First: under-outlining. If your outline lacks enough detail, it's not going to serve its purpose as a structure to guide your writing, and you will end up writing from scratch. You want to avoid this at all costs; it leads to argumentative dead ends and weak structure overall. "In high school, I wrote all my papers in one go, starting with the intro, constructing and polishing each sentence in order," explains Christine from Harvard. "In college I've become a huge fan of outline-based writing, which has made my essays much more tightly argued and given them better, clearer trajectories...since I can now shuffle topics around until they flow with some natural order and logic— rather than straining rhetorically to bridge from one idea to another."

The second mistake: over-outlining. Some students construct beautifully intricate outlines, replete with three or four levels of information, roman numerals, digits, letters, and tabs flying everywhere—the type of outline they taught you to make for your fifth-grade research project. Don't do this either. It constrains you. As Doris from Harvard explains: "One pitfall to avoid is getting stuck in the outline stage—I've seen students who spend far too much time embellishing their outlines when they should really have begun writing the paper itself long ago." When it comes time to write, you will be hampered if you constructed an outline that practically spells out what each sentence of each paragraph should say. These sorts of low-level decisions should be made when you write, not before. It's not until you're actually putting words on paper that you will understand the best way to make each small piece of your argument flow. Don't let an outline make these decisions for you. The happy medium between these two extremes is to construct a topic-level outline. Before we can cover the specifics of this process, I must first define what I mean by "topic." Here, I use the term to describe any self contained point that you might discuss in your paper. Typically, this is something more general than a piece of evidence but also more specific than a multipart argument. For example, here are some sample topics for our hypothetical paper about the Eiger:

- Our thesis about the Eiger and Swiss cultural identity
- Early written accounts of the Eiger

- The first ascent of the Eiger
- Contemporary press accounts of Eiger summit attempts
- Mentions of the Eiger in early-twentieth-century popular culture
- Mentions of the Eiger in early-twentieth-century Swiss tourist brochures
- MacMillan's thesis about the Alps and European identity
- The relationship between our thesis and MacMillan's argument
- Concluding thoughts about our thesis—implications and future work and future work

We start the outlining process by constructing a topic skeleton. This is a list of all the topics you will discuss in your paper, presented in the order that you plan to include them. Type this list directly into your computer because you will later need the ability to insert text in between items. Your topic skeleton succinctly describes the structure of your argument. For example, we might take the previously mentioned topics and order them as follows to form a topic skeleton for our hypothetical Eiger paper:

1. Mentions of the Eiger in early-twentieth-century Swiss tourist brochures
 2. MacMillan's thesis about the Alps and European identity
 3. Our thesis about the Eiger and Swiss cultural identity
 4. Early written accounts of the Eiger
 5. The first ascent of the Eiger
 6. Contemporary press accounts of Eiger summit attempts
 7. Mentions of the Eiger in early-twentieth-century popular culture
 8. The relationship between our thesis and MacMillan's argument
 9. Concluding thoughts about our thesis—implications and future work
- At this point, no specific pieces of evidence are described by our outline, but it does capture how the paper will flow. In a perfect world, you would have at least one or two good sources to support each topic.

However, it will often occur that as you formulate your topic skeleton, you come across a topic that you really need to include but for which you don't yet have any sources. That's okay. We mentioned at the end of the last step that once you start formulating your argument, you might come across some holes that need to be filled. This is exactly where these holes will become noticeable. Once you have completed your topic skeleton, you need to return to the previous step and find sources to support any of the currently unsupported topics. If you followed the research termination determination procedure from before, there shouldn't be too many of these holes.

Filling in the Details of Your Topic Outline

Once you finish your topic skeleton, and find sources for all of the unsupported topics, it's time to fill in the supporting details. This next step is crucial. As Christine from Harvard explains: "Below each bold header [in my topic skeleton], I compile in regular typeface the evidence pertaining to that header." You should actually type quotes from your research material right into the word processor document containing the outline, and label each quote with the source and page that it came from. For example, under the "first ascent of the Eiger" topic from above, you might insert quotes from a few different books on the mountain as well as excerpts from several contemporary articles. Some of these latter excerpts may also be included under the "contemporary press accounts of Eiger summit attempts" topic. It's okay to share information between topics at this point, since you will sort out which quote to use where once the writing process begins. This is not a time for caution—if it seems relevant, stick it in.

At first, this step may sound excessive. By the time you finish, your outline will be large and filled with quotes, perhaps even longer than the projected length of your completed paper. Fortunately, this process is greatly simplified by the format of your gathered research materials. Because you made a personal copy of and annotated every source, finding the appropriate pieces of evidence to include in your outline will be much easier than if you had to page through each book and article from scratch. Furthermore, the benefits of this outline far outweigh the annoyance of constructing it. As Robert, a straight-A student from Brown, explains; "I find that using this process helps me avoid digging through a pile of books and articles for each piece of information I need as I need it during writing." Remember, the goal of the straight-A approach is to separate the different components of paper construction. When it comes time to write, you don't want to be flipping through your sources, hunting down the right support. This drains your energy, increases your pain, takes time, and reduces the quality of your writing. This is why it is crucial that you extract the information from your sources in advance. Later, the writing process will be reduced to the much simpler task of simply building a framework around this already identified and organized information structure.

Step 6 Consult Your Expert Panel

“I discuss ideas with friends,” says Suzanne, a straight-A student from Brown, “and am therefore usually pretty confident with my argument by the time I sit down to write.” Suzanne reinforces a key observation: The more input you receive, the better your paper will turn out. And because soliciting advice is easy, you might as well get your outline reviewed by a group of people you trust. In the straight-A lexicon, this strategy is called “consulting your expert panel.” The technique is popular because it requires little effort on your part, but the impact on your paper quality is significant. This is the final push that transforms your thinking from interesting into compelling and your paper from competent into a standout.

Choosing Your Expert Panel

The size of your expert panel should be directly proportional to the importance of the assignment. If it's a one-page essay worth 5 percent of your grade, then your expert panel should consist of only yourself. If it's a medium-size critical analysis essay, you might aim for two opinions. If it's a major term paper worth a significant portion of your grade, then you may want to solicit feedback from as many as half-a-dozen well-chosen people. Who should sit on your panel? Your number one pick should be your professor. Unless he specifically states that he won't discuss drafts in progress (which professors sometimes do to avoid an overload of conferencing in a large class), definitely plan to bring your outline to office hours. Lay out the general shape of your argument, and the types of sources you are drawing from and where. More often than not, the professor will have some targeted advice on how to better present your points. He might suggest a new order or an added topic that should be addressed. As David from Dartmouth notes, this meeting also “will help you to create a rapport with the prof, and give you an idea of what he or she is looking for.” Yes, you've already talked with your professor in Step #3 (Seek a Second Opinion). Don't worry. There is nothing wrong with talking to a professor on two separate occasions for one paper. The first conference was quick and dealt with making sure you were starting off in the right direction. This second conference is more detailed, making sure that you managed to stay on course. Keep in mind that some students talk to their professors many times during the paper-writing process, perhaps once or twice a week. This is overkill and shouldn't be necessary if you've followed the efficient strategy laid out in this book. But rest assured that two visits are hardly monopolizing your professor's time. In addition to your professor, as David also suggests, “if you have smart friends, get their help too.”

Friends from the same class are your best bet, since they will already understand the constraints of the assignment. If you aren't close with any classmates, then tap a friend with a compatible academic background. For example, if your paper is for a history class, it makes more sense to talk to a liberal arts major than an engineering major. The former will be more familiar with this style of paper. Pick a half-hour period to sit down with each friend you chose. Explain your thesis and then run through your outline, touching on your main supporting arguments. Your friends will help you identify pieces of your structure that are unclear or unnecessary. As Jason, a straight-A student from the University of Pennsylvania, explains: "If you can explain why your argument works in a rational, step-by-step manner, and you have an arsenal of sources to cite to support the argument, then you're ready to go." One final warning: Before discussing with a classmate, make sure that collaboration of this sort is allowed. It should be no problem for research papers, but for focused critical analysis essays the professor may specifically forbid that you discuss your response with other people from the class.

Step 7 Write Without the Agony

If you've followed the Straight-A strategy so far, writing should be the most straightforward part of constructing a standout paper. This step is not mysterious. At this point, you know what to say and in what order, so all you have to do is clearly communicate your already well developed argument. "Once I have the outline, my brain relaxes," explains Jeremy, a straight-A student from Dartmouth. "I don't need to think anymore about structuring the paper, but rather just think about how to best articulate my thoughts." Note, however, that this book is not about the mechanics of writing. This is a skill that you will need to develop on your own. In general, the more you write outside of class, the better; so, to improve your skills, try to write as much as you can. Also, don't be afraid to plunk a Chicago Manual of Style above your desk or flip through well-known style guides like William Zinsser's *On Writing Well*. These can help you focus and polish your writing, and professors appreciate clear exposition. This being said, there is not much left to cover. You know what you have to do: Put words on paper. It's not easy, but, if you followed the previous steps, it won't be nearly as agonizing as most students make it. I leave you with only three succinct pieces of logistical advice to help guide you through the process of combining your writing skills with your straight-A preparation to produce the best possible paper:

Separate Your Writing from the Steps That Come Before and After

As Greta, a straight-A student from Dartmouth, explains, when it comes to the writing process she "would map out a schedule, for example, write two pages a day for five days, and then edit one day." Ryan, another Dartmouth student, admits that he "usually gave about two days for the actual writing, but the research part of the paper usually happened a few weeks before." Both of these students' habits are instructed by a simple rule:

Separate your research from your writing and your writing from your editing.

Of course, this is not always practical for a small critical analysis essay, but it's crucial for a more substantial research paper. A fresh mind produces better results. It's hard to write well when you've spent an exhausting morning researching in the library. It's equally as hard to edit carefully when you have already spent hours that day writing the words you are about to review. "Having time away from the paper," explains Jeremy from Dartmouth, "allows you to come at it with better concentration."

Write in Quiet Isolation

Writing requires substantial concentration. If you work in an area with a lot of ambient noise, you will become distracted and your efficiency will decrease dramatically. Therefore, if you have a laptop, retreat to a distant, silent corner of a faraway building to work on your writing. “I am most productive,” explains Suzanne from Brown, “in a place where I have total silence and no external stimulation—for example, the library stacks.” As I emphasized in Part One of this book, avoid, if possible, study lounges, crowded areas of the library, and public computer labs. These places are noisy, and, as Rielle from Brown warns: “You’re always running into people and getting snagged by fascinating conversations.” If you don’t have a laptop, then work at the computer in your room at times when your roommates are in class or at meetings. If necessary, arrange in advance to kick them out for a few hours so you can work in peace. In addition, you should schedule your writing to correspond to your energetic high points during the day. For me, this meant working right after breakfast with my first cup of coffee. For others, this might be the early evening, right before dinner, or the afternoon after a post-lunch workout. The key is to recognize that writing is perhaps the most demanding (in terms of focus required) intellectual activity you will do while a college student. More so than reading, solving problem sets, or studying, writing demands all the energy and focus that you can manage.

Follow Your Outline and Move Slowly

Chris from Dartmouth offers simple advice for tackling the writing process: “I use the outline I’ve created as a guide and just sort of build from that, taking it one paragraph at a time.” Follow this example. Use your outline to direct your writing, setting up and expounding on each of the topics in a clear, cogent way, and copying and pasting quotes directly into your paper wherever needed. Keep your attention focused on the topic at hand. Your mind is free from concerns of structure and sources at this point, so you can concentrate on articulating specific points clearly and strongly. Always make sure your current point reads clearly before moving on to the next. Some students have success by writing their first draft quickly and sloppily, and then returning to clean it up in many successive editing rounds. In your case, however, because you’re working from a detailed topic outline, it will end up being quicker to write carefully the first time. Moving fast tends to produce time-consuming dead ends later on, and ultimately necessitates major rewrites. And, believe it or not, that’s all you need to know. So stop fearing writing! If you follow this system, this step, though still challenging, won’t take an excessive amount of time. Leave

the all-nighters to the average students, get your first draft done quickly and effectively, and then go have some fun.

Step 8 Fix, Don't Fixate

Editing your paper is important, and this shouldn't come as a surprise. If you hand in pages containing spelling and grammatical mistakes, the professor will be more than disappointed—she's likely to lower your grade as a result. Even if your argument is brilliant, it's really hard to get past those simple errors. This last step of the paperwriting process aims to free your work of these imperfections. At the same time, however, you don't want to overedit. Many students fixate on these fixes, and end up devoting hours to reviewing draft after draft. This act of academic self-flagellation is especially prevalent when working on big research papers. After all the work you dedicate to crafting a masterpiece of an argument, you begin to fear letting your baby out into the world. It's sort of like suffering from a nerdy version of Stockholm Syndrome— and it's a drag. “You can edit a paper forever and still not be satisfied,” explains Frank from Brown. “So it's important to know when to just print the damn thing out and send it off to its fate.” The goal here is to devise a simple system, something you can follow for every paper to help you root out the embarrassing typos and confusing constructions but also to prevent you from becoming a grammar psycho. Drawing from the advice given in my straight-A interviews, I present in this step a system that meets these criteria. It involves three simple passes through your draft. No more and no less. For those of you who are used to endless editing runs, the idea that three passes is enough might sound suspiciously quick. Or, if you're the kind of person whose idea of proofreading is hitting the spell-check button, multiple runs might seem hopelessly time consuming. But rest assured, the system is efficient and it gets the job done. As we will soon discuss, the key is the specific kind of attention given to each pass. Here is how it works:

The Argument Adjustment Pass

Your first pass through your work should be conducted on your computer. Read carefully, and focus on the on your computer. Read carefully, and focus on the presentation of your arguments—don't worry about small grammatical mistakes for the moment. Take in the paper one paragraph at a time. If a section is awkwardly stated, clarify the sentences. If it makes a point you already explained earlier, ruthlessly cut it out. If the argument is lacking detail, add in more sentences as necessary to fully explain your point. If a transition is lacking between topics or paragraphs, add one. Also be on the lookout for any major structural issues. Sometimes you don't realize until you finish an entire draft that your topic outline wasn't optimal. Don't be afraid to shift around major chunks of text. This is your

chance to make serious edits to the structure of your paper, so take this seriously. Do this editing at a time when you are rested and unhurried by upcoming appointments. For a large paper, spread this pass out over several days if possible. When you're done, your paper may still contain small mistakes. That's okay. You'll fix those next. The goal here is to tweak the argument until you're satisfied that it makes every point that you want to make in the order that you want to make them. Once you're done with this pass, these big picture details are locked in.

The Out Loud Pass

The Argument Adjustment pass is important, but not sufficient by itself. As Robert from Brown explains: "My papers always read differently on the page than on the screen." And as Melanie, a straight-A Dartmouth student, adds: "having a hard copy to read and mark up was absolutely necessary." Accordingly, for this next pass, you should first print out a copy of your paper, and then take it where you can have some privacy. With a pencil in hand, and this is the important part, begin to read your paper out loud. Don't cheat. Use a strong voice and articulate each word as if you're delivering a speech. For a long paper, it may take a long time to read the entire thing, so be prepared to split this into several sessions. You might also want water or hot tea on hand to prevent you from losing your voice. Whatever you do, however, don't avoid actually articulating every word. Whereas the last pass focused on your arguments, the goal of this pass is to root out small mistakes that might otherwise distract a reader from your engaging thesis. While reading, whenever you come across a grammatical mistake or an awkward construction, mark it clearly on the printout. Then go back up to the beginning of the preceding paragraph and start reading again. After you have marked up the entire document, go back to your computer and enter the changes you noted on your printout. A word of warning—this process always takes longer than expected, so leave yourself plenty of time. The rationale behind this approach is simple. As Ryan from Dartmouth explains: "Reading it out loud helps you catch typos or strange wording better than reading it in your head." No matter how many times you review a draft, if you're scanning silently, there are certain awkward phrases you might skip over every time—our subconscious minds have a habit of patching over these mistakes when reading our own writing. When you say the words out loud, on the other hand, your ear will catch even minor problems and draw your attention to them. "Something that looks fine on paper will jump out as strange or poorly worded when you hear it," explains Jeremy from Dartmouth. Therefore, by reading the paper out loud, you

will catch most mistakes in your paper in just one pass—requiring much less time than the multiple silent reviews necessary to achieve similar results.

The Sanity Pass

Because the previous passes were so careful, you're almost done, and you've only read through your work twice so far! Just to be sure that something embarrassing didn't slip through, it's a good idea to make a final, quick pass through a printed copy of your paper before handing it in. You don't have to do this pass out loud, and feel free to move through it quickly. But definitely use a printed copy, rather than reading on your computer screen, since a hard copy has a better chance of revealing a typo. If possible, separate this pass from the previous two. In fact, it's fine to do this the morning of the deadline. At this point, there should be no major mistakes lurking in your document. The goal here is twofold.

First, as mentioned, this last pass catches stray mistakes.

"I tried to always reread my papers before handing them in," explains James, a straight-A student from Dartmouth. "I try to smooth out any last kinks in the flow during that final editing."

Second, and perhaps more important, it also provides closure on your paper.

Because your work is so polished by this point, this final read-through should essentially go smoothly. As a result, you will develop a better feel for the flow and enjoy the experience of watching your argument unfold. This should help put your mind at ease. After all your work, think of this last pass as your reward. A final review before the paper leaves your hands, probably never to be read by you again. That's why we call it a sanity pass. Once you hand in your paper, you can now confidently tell yourself: "Unless I'm going insane here, I'm pretty sure that I just handed in a damn good piece of writing!"

Part Three Cheat Sheet

Step #1. Target a Titillating Topic

- Start looking for an interesting topic early.

Step #2. Conduct a Thesis-Hunting Expedition

- Start with general sources and then follow references to find the more targeted sources where good thesis ideas often hide.

Step #3. Seek a Second Opinion

- A thesis is not a thesis until a professor has approved it.

Step #4. Research like a Machine

- Find sources.
- Make personal copies of all sources.
- Annotate the material.
- Decide if you're done. (If the answer is "no," loop back to #1.)

Step #5. Craft a Powerful Story

- There is no shortcut to developing a well-balanced and easy-to-follow argument.
- Dedicate a good deal of thought over time to getting it right.
- Describe your argument in a topic-level outline.
- Type supporting quotes from sources directly into your outline.

Step #6. Consult Your Expert Panel

- Before starting to write, get some opinions on the organization of your argument and your support from classmates and friends who are familiar with the general area of study.
- The more important the paper, the more people who should review it.

Step #7. Write Without the Agony

- Follow your outline and articulate your points clearly.
- Write no more than three to five pages per weekday and five to eight pages per weekend day.

Step #8. Fix, Don't Fixate

- Solid editing requires only three careful passes:
 - The Argument Adjustment Pass: Read the paper carefully on your computer to make sure your argument is clear, fix obvious errors, and rewrite where the flow needs improvement.
 - The Out Loud Pass: Carefully read out loud a printed copy of your paper, marking any awkward passages or unclear explanations.
 - The Sanity Pass: A final pass over a printed version of the paper to check the overall flow and to root out any remaining errors.

Step 109-Thinking, Logic and Mental Model

1. Listen, Follow and Apply Thinking, Logic and Mental Model PART 7

Part 7: Thinking, Logic and Mental Model For Deep Work or Deep Study, Or Bible Study

- 1. Step 57- Slow Down. Pages 1061-1063.**
- 2. Step 58- NOT MULTITASK. Pages 1064.**
- 3. Step 59-You Have Required To Do The Work For Thinking and Applying Mental Tool Models. Pages 1065-1080.**
- 4. Step 60-Why Critical Thinking, Logic, Thinking and Mental Tools Are Important? Pages 1081-1083.**
- 5. Step 61-Intradisciplinary Thinking. Pages 1084-1125.**
- 6. Step 62-Multidisciplinary Thinking. Pages 1126-1168.**
- 7. Step 63-CrossDisciplinary Thinking. Pages 1169-1211.**
- 8. Step 64-Interdisciplinary Thinking. Pages 1212-1254.**
- 9. Step 65-Transdisciplinary Thinking. Pages 1255-1298.**
- 10. Step 66-Journaling. Pages 1299.**
- 11. Step 67-Letting The World Do The Work For You. Pages 1300-1305.**
- 12. Step 68-Journaling. Pages 1306.**
- 13. Step 69-Letting The World Do The Work For You. Pages 1307-1312.**

Step 110-Letting The World Do The Work For You

1. Listen and Apply book
 - I. This Explains Everything_ Deep, Beautiful, and Elegant Theories of How the World Works
2. **The world never tells you that you're wrong; it only gives you outcomes.**
3. **Don't force. Don't resist. Have a beginner's mind. Let the world teach you.**
4. **Reality will do a lot of the work for us if we simply align with it. Most of the time we're simply adding friction because we want the world to work in the way we think it should.**
5. **If you don't see the world the way it is, you'll think it works in a way that it doesn't and make terrible mistakes. The key to getting what you want out of life is to identify how the world works and align yourself accordingly. This is hard because we think the world should work the way we see it. The word "should" is important. Because we think the world should work in a way that it doesn't, our approach is suboptimal. What the pupil must learn, if he learns anything at all, is that the world will do most of the work for you, provided you cooperate with it by identifying how it really works and aligning with those realities. If we do not let the world teach us, it teaches us a lesson. Joseph Tussman.**
6. When an outcome is not what you want it to be, things get tough. You can ignore the result and continue to think that you're right. This protects your ego. It also carries the risk of your continuing to believe something that isn't true. Alternatively, you can calibrate your believability on the subject at hand by lowering the odds that you're right. For example, maybe you gave yourself an 85 out of 100 for the ability to hold a firm opinion on this subject, and now you lower your score to 75. If the world continues to provide undesirable outcomes, eventually you get the hint and change your beliefs. Finally, you can give up your opinions and just respond to the world as it is. This option is the hardest.
7. You do not create the way the world works, you can only align yourself with it. It takes a lot of work to align ourselves with reality. When we don't get the outcome we're seeking, the last place we look is inside ourselves. Instead, we blame others or

circumstances. If you want to align yourself with reality, you have to work at it and care about it. There are two keys to aligning yourself with how the world really works: accepting feedback and stopping bargaining.

- I. We let people, not results, guide our behavior. The world tries to tell us when we don't see it the way it is. The problem is we don't listen to the world. Instead, we let others tell us what's right and wrong, what works, and what doesn't. Common actions get common results. Most of our actions come from others. We want what they want. Even worse, we employ the same actions to get it. This isn't always wrong. If you're just starting, the quickest path to average is to copy. If you want better results than average, you're going to have to iterate. Doing something different means we might look like a fool, and we do not want to look like a fool. Iterating means trying something new, it means you might fail. Show me a person who's afraid to look bad, and I'll show you a person you can beat every time. If we do what everyone else is doing, we're going to get the same results that everyone else is getting. Different results demand different actions. If you can't really fail, you can't really succeed. Let results, not popularity, determine your actions. If you're doing something that doesn't get you the results you want, try something new. If you're doing something that seems to work, keep doing it. Consistently repeat successful actions.
- II. Bargaining with the world doesn't work. A lot of otherwise smart people know what they're doing isn't getting the results they want, but because they think the world *should* work in a way that it doesn't, they keep repeating them hoping for different results. If you are this person, see it for what it is, and change your actions. The feedback from the world is often painful. Often, it is this very pain that causes us to no longer delude ourselves with how the world should work and accept how it does work. If you can learn to accept the world for how it is, before suffering, you'll go faster and further. Outcome over ego. If you think you know how the world works but you're doing something that gets suboptimal results because it *should* work a different way, you don't really know how the world works. Rational people take feedback from the world. If you want to know how someone sees the world, look at their actions. In the end, it's all your fault. You are accountable for your outcomes. When you take responsibility for your outcomes, you naturally accept feedback from reality. When you get feedback from reality, you adjust your behavior.

- III. As Per Kobe Bryant statement: Trivial things should not be taken your attention. The attentions should be focused on things that is very important. Anything outside of the most important things in life, you should not have time for. You Should love the challenge in life, and always be curious, if you can be at the top , as these greats in that area. Always focus on one thing and not multiple things, this gives an edge and advantage over other people, who focusing on multiple things in life. The World Becomes a library to you, to be better at your craft.: Everything you see whether TV show I saw, Books, Journals, I read, whether discussion, debate I listen, people I talk to. Everything was done to try to learn to become better at the craft your focusing. When you have this point of you, then the world becomes your library to help you to become better at the craft.
- IV. Have the best work ethic on daily basis. This is everyday process, and try to figure it out, the strengths and weaknesses of my position and opposing person position.
- V. Always look at the reality of the situation, and do not let the emotion cloud the situation and the execution. Always be in the present and the moment.
- VI. If you understand the world as it really is, not as you'd wish it to be, you will begin to make better decisions almost immediately. Once you start making better decisions the results compound. Better initial decisions free up your time, reduce your stress, allowing you to spend more time with your family and leave your competition in the dust.
- VII. How can we best understand the world as it is? Acquiring knowledge can be a very daunting task. If you think of the mind as a toolbox, we're only as good as the tools at our disposal. A carpenter doesn't show up to work with an empty toolbox. Not only do they want as many tools in their toolbox as possible, but they want to know how to use them. Having more tools and the knowledge of how to use them means they can tackle more problems. Try as we might, we cannot build a house with only a hammer. If you're a knowledge worker, you're a carpenter. But your tools aren't bought at a store and they don't come in a red box that you carry around. Mental tools are the big ideas from multiple disciplines, and we store them in our mind. And if we have a lot of tools and the knowledge required to wield them properly, we can start to synthesize how the world works and make better decisions when confronted with problems.
- VIII. This is how we understand and deal with reality. The tools you put into your toolbox are Mental Models. Mental models are a framework for understanding

how the world really works. They help you grasp new ideas quickly, identify patterns before anyone else and shift your perspective with ease. Mental Models allow us to make better decisions, scramble out of bad situations, and think critically. If you want to understand reality you must look at a problem in multiple dimensions — how could it be otherwise? Getting to this level of understanding requires having a lot of tools and knowing how to use them. You knew there was a hitch right? We need to change our fast-food diet of information consumption and adopt the healthier diet of knowledge that changes slowly over time. While changing diets isn't easy, it can be incredibly rewarding: more time, less stress, and being better at your job. The costs, however, are short term pain for long-term gain. You must change how you think.

- IX. 2nd Order Thinking. One example of a model we can immediately conceptualize and use to improve our ability to make better decisions is something we can borrow from ecology called second-order thinking. The simple way to conceptualize this is to ask yourself "If I do X, what will happen *after* that?". I sum this up using the ecologist Garrett Hardin's simple question: "And then what?" A lot of people forget about higher order effects — second and third-order effects or higher. I've been in a lot of meetings where decisions are made and very few people think to the second level, let alone the third. Rather, what typically happens is called first conclusion bias. The brain shuts down and stops thinking at the first idea that comes to mind that seems to address the problem as you understand it. We don't often realize that our first thoughts are usually not even our own thoughts. They usually belong to someone else. We understand the sound-byte but we haven't done the hard work of real thinking. After we reach the first conclusion, our minds often shut down. We don't seek evidence that would contradict our conclusion. We don't ask ourselves what the likely result of this solution would be — we don't ask ourselves "And then what?" We don't ask what other solutions might be even *more* optimal. For example, consider a hypothetical organization that decides to change their incentive systems. They come up with a costly new system that requires substantial changes to the current system. Only they don't consider (or even understand) the problems that the *new* system is likely to create. It's possible they've created more problems than they've solved — only now there are *different* problems they must put their head down to solve. Optically, they "reorganize their incentive programs," but practically, they've simply expended energy to stay in place. Another, perhaps more complicated,

example is when a salesman comes into a company and offers you a software program he claims will lower your operating costs and increase your profits. He's got all these beautiful charts on how much more competitive you'll be and how it will improve everything. This is exactly what you need because your compensation is based on increasing profits. You're sold. Then second-order thinking kicks in and you dare to ask how much of those cost savings are going to go to you and how much will eventually end up benefits enjoyed by customers? To a large extent, that depends on the business you're in. However, you can be damn sure the salesman is now knocking on your competitor's door and telling them you just bought their product and if they want to remain competitive they better purchase it too. Eventually, you all have the new software and no one is truly better off. Thus, in the manner of a crowd of people standing on their tip-toes at a parade, all competitors spend the money but none of them win: The salesman wins and the customer wins. We know, thanks to people like Garrett Hardin, Howard Marks, Charlie Munger, Peter Kaufman, and disciplines like ecology, that there are second and third-order effects. This is how the world really works. It just isn't always a comfortable reality. Understanding how the world works isn't easy and it shouldn't be. It's hard work. If it were easy, everyone would do it. And it's not for everyone. Sometimes, if your goal is to maximize utility, you should focus on getting very, very good in a narrow area and becoming an expert, accepting that you will make many mistakes outside of that domain. But for most, it's extremely helpful to understand the forces at play outside of their narrow area of expertise. Because when you think about it, how could reality be anything other than a synthesis of multiple factors? How could it possibly be otherwise?

- X. When our mental models line up with reality, they help us avoid problems. However, they also cause problems when they don't line up with reality as we think something that isn't true.
- XI. We must be open to other perspectives if we truly want to understand the results of our actions. Despite feeling that we've got all the information, if we're on the ship, the fish in the ocean has more he can share. The second flaw is ego. Many of us tend to have too much invested in our opinions of ourselves to see the world's feedback—the feedback we need to update our beliefs about reality. This creates a profound ignorance that keeps us banging our head against the wall over and over again. Our inability to learn from the world because of our ego happens for many reasons, but two are worth mentioning here. First, we're so

afraid about what others will say about us that we fail to put our ideas out there and subject them to criticism. This way we can always be right. Second, if we do put our ideas out there and they are criticized, our ego steps in to protect us. We become invested in defending instead of upgrading our ideas. The third flaw is distance. The further we are from the results of our decisions, the easier it is to keep our current views rather than update them. When you put your hand on a hot stove, you quickly learn the natural consequence. You pay the price for your mistakes. Since you are a pain avoiding creature, you update your view. Before you touch another stove, you check to see if it's hot. But you don't just learn a micro lesson that applies in one situation. Instead, you draw a general abstraction, one that tells you to check before touching anything that could potentially be hot. Organizations over a certain size often remove us from the direct consequences of our decisions. When we make decisions that other people carry out, we are one or more levels removed and may not immediately be able to update our understanding.

*PART 16: Deep Work, Strategy
and Tactics.*

Step 111-Slow Down

- 1. Do Not Rush Any Tasks I will do At Any Time.**
- 2. Listen and Apply Book “The Slow Fix Solve Problems, Work Smarter, and Live Better in a World Addicted to Speed”**
- 3. Listen and Apply Book *In Praise Of Slowness Challenging the Cult of Speed BY Carl Honore.**

- I. We live in a world scarce of understanding and abundant with information. We complain that we never have any free time yet we seek distraction. If work can't distract us, we distract ourselves. We crave perpetual stimulation and motion. We're so busy that our free time comes in 20 second bursts, just long enough for us to read the gist and assume we understand. If we are to synthesize learning and understanding we need time to think.
- II. The modern storm of bits and stimulation, relents only when we sleep. (And then only if we remember to turn off the phone.) Lost in all of this is the art of stillness. We live in a world with more information than ever and yet we understand less. We have come into the belief that the simple act of reading confers understanding. Worse, most of our reading is elementary reading, or skimming — a far cry from syntopical reading, which seems more fertile for the mind willing to do the work.
- III. But that's just it. We don't want, or can't find the time, to do the work that's required to hold an opinion. It's much easier to simply read the opinions of another and let them think for us.
- IV. Understanding comes from focusing, chewing, and relentlessly ragging on a problem. It comes with false starts, dead ends, and frustration. Thinking requires time and space. It's slow. It means saying I don't know. In short, thinking is everything the modern workplace is designed to eradicate.
- V. We're expected to have an opinion about everything and yet our time to think is near zero. We hold more opinions than ever but have less understanding. We don't even understand ourselves. How could it be otherwise?
- VI. As Milan Kundera wrote in his 1996 novella Slowness, “When things happen too fast, nobody can be certain about anything, about anything at all, not even about himself. “In our fast-moving modern world, it always seems that the time-train is

pulling out of the station just as we reach the platform. No matter how fast we go, no matter how cleverly we schedule, there are never enough hours in the day.”

VII. Carl Honore, wrote a book, In Praise of Slowness: Challenging the Cult of Speed, to explore why we’re always in such a rush, what if anything is the cure for time-sickness, and whether it’s desirable to slow down. The book is not an all-out declaration of war against speed. Speed has helped to remake our world in ways that are wonderful and liberating. Who wants to live without the Internet or jet travel? The problem is that our love of speed, our obsession with doing more and more in less and less time, has gone too far; it has turned into an addiction, a kind of idolatry. Even when speed starts to backfire, we invoke the go-faster gospel.

VIII. When we rush, we skim the surface, and fail to make real connections with the world or other people.” Moreover we don’t make connections with ideas. We don’t synthesize. We don’t test theories over time. We don’t play with ideas.

IX. The implications on thinking are fascinating. We are all fast-thinkers now. We have forgotten how to look forward to things, and how to enjoy the moment when they arrive. Restaurants report that hurried diners increasingly pay the bill and order a taxi while eating dessert. Many fans leave sporting events early, no matter how close the score is, simply to steal a march on the traffic. Then there is the curse of multi-tasking. Doing two things at once seems so clever, so efficient, so modern. And yet what it often means is doing two things not very well. Like many people, I read the paper while watching TV— and find that I get less out of both. In this media-drenched, data-rich, channel-surfing, computer-gaming age, we have lost the art of doing nothing, of shutting out the background noise and distractions, of slowing down and simply being alone with our thoughts. Boredom — the word itself hardly existed 150 years ago— is a modern invention. Remove all stimulation, and we fidget, panic and look for something, anything, to do to make use of the time. When did you last see someone just gazing out the window on a train? Everyone is too busy reading the paper, playing video games, listening to iPods, working on the laptop, yammering into mobile phones. Instead of thinking deeply, or letting an idea simmer in the back of the mind, our instinct now is to reach for the nearest sound bite. In modern warfare, correspondents in the field and pundits in the studio spew out instant analyses of events as they occur. Often their insights turn out to be wrong. But that hardly matters nowadays: in the land of speed, the man with the instant response is king. With satellite feeds and twenty-four-hour news channels, the electronic media is dominated by what one

French sociologist dubbed “le fast thinker”— a person who can, without skipping a beat, summon up a glib answer to any question.

- X. Fast eats time. One consequence of fast is that we make poor decision after poor decision. Those decisions don't go away never to be seen again. It's not like we make a bad decision and we're done with it. No, the consequences are much worse. Poor decisions eat time. They come back to haunt you. They create issue after issue. They feed into the perpetual motion machine of busyness. And in a culture where people wear busyness as a badge of honor bad decisions actually lead us to think that we're doing more.

4. Do The Tasks Slowly, and Step By Step.

5. The Art of Slowing down and Do Not Rush Anything.

- I. The Art of Stillness is a persuasively argued case for the pleasures of slowing down and being in one place. Today we're going faster and faster in search of contentment and meaning. This is largely a recipe for ensuring we will never be happy. We have the sense, too often, of running at top speed and never being able to catch up.
- II. Too many of us see going nowhere as turning away from something rather than turning towards something.
- III. Going nowhere isn't about turning your back on the world; it's about stepping away now and then so that you can see the world more clearly and love it more deeply. “There is nothing either good or bad, but thinking makes it so.”
- IV. The idea behind choosing to sit still long enough to learn about yourself is simple and has been around for ages. Marcus Aurelius and Epictetus reminded us many millennia ago that it's how we respond to our experiences, not the experiences themselves, which shape us.
- V. The greatest weapon against stress is our ability to choose one thought over another. Part of making better decisions is making time to think. Something that few of us are able to do.
- VI. “Our creations come not when we're out in the world, gathering impressions, but when we're sitting still, turning those impressions into sentences.

Step 112 - NOT MULTITASK.

1. Of course you can do more than one thing at once. The catch is you can't do more than one thing at once that requires concentration. You can walk and chew gum, but you can't write an email and a report at the same time. When you're doing two things at once that are cognitively demanding, what you're really doing is switching back and forth very quickly from one task to another.
2. There is a mental cost—called a switching cost—to all of this multitasking. But that's not all it makes deep thinking impossible.
3. I think people that multitask pay a huge price. They think they're being extra productive, and I think they're (out of their mind). I use the metaphor of the one-legged man in the ass-kicking contest. I think when you multi-task so much, you don't have time to think about anything deeply. You're giving the world an advantage you shouldn't do. Practically everybody is drifting into that mistake. Concentrating hard on something that is important is. I can't succeed at all without doing it. I did not succeed in life by intelligence. I succeeded because I have a long attention span.
4. It sounds counter-intuitive but if you want to increase discretionary time and reduce stress you need to schedule time to think. The tiny fragments of time many of us find ourselves with have a negative effect on our ability to think deeply about a problem. Furthermore they impede our ability to learn — we stay at a surface level and never move into a deep understanding. Deresiewicz warns: "You simply cannot (think) in bursts of 20 seconds at a time, constantly interrupted by Facebook messages or Twitter tweets, or fiddling with your iPod, or watching something on YouTube."
5. The opposite approach is to focus on a problem or subject and try to achieve a deep fluency. How many of us, however, have time? We don't do the work required to have an opinion. Instead we operate with surface knowledge. We tackle problems with the first thought that comes to mind. Because we make a poor initial decision, we spend countless hours attempting to correct it. No wonder we have no time to think. We're not heeding the advice of Joseph Tussman and letting the world do the work for us.
6. Listen and Apply The Following Books:

A. The Multitasking Mind By Dario Saliveci

Step 113-You ARE Required To Do The Work For Strategy and Tactics.

1. When Give Opinion on Anything, Do Not Be so Angry and Mean to Others.
2. People Need To Stop Doing By Coming Unprepared To Give Opinion On Any Subject, Without Having Good Idea Of The Literature, and Arguments Written on Topic and Theme Available To Them. The people coming unprepared and not doing any Hard Work To Have an Opinion On The Subject or Topic. When People Coming Overconfidence, which could be resulting in Lack of Preparation, Which Could Lead That Your Position can be Destroyed with Ease. They simply won't do the work required. It's easy to come home, sit on the couch, watch TV, and zone out until bedtime rolls around. But that's not going to help you get smarter.
 - A. People Who Do Not Put The Required Work: The first thing they always do is tell you what they think. When someone has an opinion about everything, they want to share it with you. They often tout stats and research as if they had an imaginary checklist of facts they need to be able to rattle off to establish themselves as an expert in a field they actually know very little about. Because they have an opinion on everything, they are quick to judge others – for their lack of opinions, for their lack of knowledge, for their lack of outrage, and the list goes on.
 - B. People who have opinions about everything barf so much noise that it's hard to find the signal. Your brain has to work overtime to figure out if they did the work to come up with their opinions themselves or if they're simply regurgitating some oped in a newspaper. Over time, opinionated people also end up in their own prisons and they try to take you with them.
 - C. The problem comes from how we see the world. Our opinions are often rooted in how we think the world should work, according to our morals, values, and principles. If we see the world through the lens of our opinions, much of what happens will not agree with us. This is feedback, and how we respond to this feedback is key.

3. How to Get Smarter Read. A lot. Warren Buffett says, "I just sit in my office and read all day." What does that mean? He estimates that he spends 80% of his working day reading and thinking. When asked how to get smarter, Buffett once held up stacks of paper and said, "Read 500 pages like this every week. That's how knowledge builds up, like compound interest." All of us can build our knowledge, but most of us won't put in the effort. "Go to bed smarter than when you woke up."
4. How Long Does it Take To Prepare:
 - A. Depend on the topic and opponent, and how much he's written.
 - B. If the opponent nothing published, then there was very little preparation to be made because I simply didn't know what to expect.
 - C. On the other hand, if the opponent has published lots of written work and have some videos. Read and what his written and videos and prepare the summaries articles, videos, and have sense where he is coming from. This can take Weeks or Months.

5. Before Preparation. The difference between the people who do the work and the people who just reel off memorized opinions is huge. When you do the work, you can answer the next question. You know when to follow the rules and when they'll get you in trouble. When I did my postgraduate I was surrounded by people who could answer the test questions. They got good grades — actually, they got *great* grades but an odd thing happened after school: a lot of those people couldn't apply their knowledge to problems they hadn't seen before. They were chauffeurs — they knew the memorized answer. They couldn't answer the next question. We're all chauffeurs in some aspects of our lives. This is why understanding your circle of competence is so critical to living a rational life.

I. Circle of Competence:

A. **Circle Of Competence**-Understanding my Circle of Competence helps to avoid problems, identify opportunities for improvement and learn from Others. Circle of Competence is simple: Each of us, through experience or study, has built up useful knowledge on certain areas of the world. Some areas are understood by most of us, while some areas require a lot more specialty to evaluate. For example, most of us have a basic understanding of the economics of a restaurant: You rent or buy space, spend money to outfit the place and then hire employees to seat, serve, cook, and clean. (And, if you don't want to do it yourself, manage.) From there, it's a matter of generating enough traffic and setting the appropriate prices to generate a profit on the food and drinks you serve—after all of your operating expenses have been paid. Though the cuisine, atmosphere, and price points will vary by restaurant, they all have to follow the same economic formula. That basic knowledge, along with some understanding of accounting and a little bit of study, would enable one to evaluate and invest in any number of restaurants and restaurant chains, public or private. It's not all that complicated. Far more important is to honestly define what we do know and stick to those areas. Our circle of competence can be widened, but only slowly and over time. Mistakes are most often made when straying from this discipline. Where should we devote our limited time in life, to achieve the most success? So, the simple takeaway here is clear. If you want to improve your odds of success in life and business, then define the perimeter of your circle of competence, and operate inside. Over time, work to expand that circle

but never fool yourself about where it stands today, and never be afraid to say “I don’t know.”

II. Two Type of Knowledge: The Max Planck and Chauffeur Test

A. The Two Types of Knowledge: The Max Planck and Chauffeur Test: How to distinguish between the two types of knowledge: real knowledge and pretend knowledge.

- The first type of knowledge is real. It can’t be bought. It can’t be copied. If you want real knowledge you need to earn it. One is Planck knowledge, the people who really know. They’ve paid the dues, they have the aptitude. You are going to have the problem in your life of getting the responsibility into the people with the Planck knowledge and away from the people with the chauffeur knowledge. Real knowledge comes when people do the work. The problem is that it’s difficult to separate the two. This is the Batesian Mimicry problem. One way to tease out the difference between Planck and chauffeur knowledge is to ask them why.
- The second type of knowledge is copied. On the surface you know the answer but you lack the understanding to show your work. Then we’ve got chauffeur knowledge. They’ve learned the talk. They may have a big head of hair, they may have fine temper in the voice, they’ll make a hell of an impression. But in the end, all they have is chauffeur knowledge. I think I’ve just described practically every politician in the United States. We have the people who don’t do the work — they pretend. While they’ve learned to put on a good show, they lack understanding. They can’t answer questions that don’t rely on memorization. They can’t explain things without using jargon or vague terms. They have no idea how things interact. They can’t predict the consequences. The problem is that it’s difficult to separate the two. This is the Batesian Mimicry problem. One way to tease out the difference between Planck and chauffeur knowledge is to ask them why.
- How To Distinguish Real Knowledge and Fake Knowledge. With journalists, it is more difficult. Some have acquired true knowledge.

Often they are veteran reporters who have specialized for years in a clearly defined area. They make a serious effort to understand the complexity of a subject and to communicate it. They tend to write long articles that highlight a variety of cases and exceptions. The majority of journalists, however, fall into the category of chauffeur. They conjure up articles off the tops of their heads or, rather, from Google searches. Their texts are one-sided, short, and— often as compensation for their patchy knowledge. The same superficiality is present in business. The larger a company, the more the CEO is expected to possess “star quality.” Dedication, solemnity, and reliability are undervalued, at least at the top. Too often shareholders and business journalists seem to believe that showmanship will deliver better results, which is obviously not the case. One way to guard against this is to understand your circle of competence. Dobelli concludes with some advice worth taking to heart. Be on the lookout for chauffeur knowledge. Do not confuse the company spokesperson, the ringmaster, the newscaster, the schmoozer, the verbiage vendor, or the cliché generator with those who possess true knowledge. How do you recognize the difference? There is a clear indicator: True experts recognize the limits of what they know and what they do not know. If they find themselves outside their circle of competence, they keep quiet or simply say, “I don’t know.” This they utter unapologetically, even with a certain pride. From chauffeurs, we hear every line except this.

III. Batesian Mimicry Problem. Batesian Mimicry: Why Copycats Are Successful.

Mimic and the Real Thing:

- A. "There's two kinds of snakes you come across. There's the Texas Coral Snake, and the Mexican Milk Snake, and they both look exactly alike. The Texas Coral Snake is dangerous, it's venomous, it can kill you in a minute. The Mexican Milk Snake can't do anything to you; it's an impostor." How is it that these two look alike? It's due to a phenomenon called Batesian Mimicry.
- B. In the 1850s, the naturalist Henry Walter Bates found a certain set of butterflies who were clearly *not* of the same species but whose wings looked almost the same to the naked eye. After thinking it over, Bates eventually figured out what was going on: While the butterflies which were toxic to potential predators (the "models") were able to operate freely and relatively unmolested, there had also developed a "mimic" population of butterflies which wasn't toxic at all, yet still went untouched! In fact, biologists eventually figured out that the more toxic and dangerous the "model" was and the more frequently they appeared in the local population, the easier it was for its "mimics" to get by! Predators simply wouldn't take the risk of mixing up the two. If there aren't as many "models" around or they aren't that dangerous, the mimics have a harder time.
- C. This is a wonderful model, and in the practical world we live in, a similar phenomenon abounds: Copycats or "pretenders to the throne" are often very effective, very convincing "mimics" of the true champions. They dress the part, they talk the talk, and they know what buttons to push. But in the end, they are merely chauffeurs. We see a very Batesian effect at work: The more impressive the "model," the more effective its mimics can be in convincing people they too are impressive, and in all the same ways. But for every Warren Buffett (just one by our count), there has been many "future" Warren Buffett's. For every Steve Jobs, there have been many "next" Steve Jobs'. In fact, sometimes even just *appearances* can be quite convincing: now-disgraced Theranos founder Elizabeth Holmes was very fond of wearing a very Steve Jobsian black turtleneck outfit. Because they can be very convincing, we must be wise enough to watch out for Batesian mimicry

— even in ourselves. This brings up an interesting, at times paradoxical, question: Who can best tell the difference between a Coral Snake and its Mimics? The Coral Snake itself. The real thing knows a fake. It's worth taking the time to work on learning all the big ideas you can find, not just the ones you want to learn. In that search, you'll find a host of big winners you didn't even know existed.

6. Preparation:

- A. While we all hold an opinion on almost everything. Have I do the work required to have an opinion on any Subject? Never allow myself to have an opinion on anything that I don't know the other side's argument better than they do. The work required to have an opinion is very hard part, have I avoid it?
 - I. I have to do the reading.
 - II. I have to talk to competent people and understand their arguments.
 - III. Never try to be biased toward any of the side, but question both side of the argument.
 - IV. Do not support any side, until all the facts are put out there, clear and obvious.
 - V. Once known all the facts then analyse both sides of the argument like William Lane Craig.
 - VI. I have to think about the key variables and how they interact over time.
 - VII. I have to listen and chase down arguments that run counter to your views.
 - VIII. I have to think about how you might be fooling yourself.
 - IX. I have to see the issue from multiple perspectives.
 - X. I have to think.
 - XI. I need to become your most intelligent critic and have the intellectual honesty to kill some of your best-loved ideas.
 - XII. Be honest with yourself and open minded. ANALYSE both side of the argument logically and see which is true logically. Means has the clear terms, premises are true, and conclusion follows from premises.
 - XIII. Never say your opinion about anything that requires the analysis of the arguments and facts. Work very bery hard to have an opinion about anything.
 - XIV. Listen very carefully other side and use ancient method *state the opposition argument in my own words and ask him/her if the argument I

stated in my own words represents correctly their argument and if I UNDERSTOOD Correctly their arguments.

XV. Never use cheap shots to win argument, like logical fallacies.

XVI. Debate and discussion is not about just win at any cost, but let other person to think about your arguments and engage with them. Second reason never use in discussion cheap shots toward other person, but be civil. Third reason is win the debate and discussion. Fourth is find the truth.

B. For Affirmative and Negative Case:

- I. Read, analyse, Research, Syntopicon and Investigate Published Work.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of My own Arguments
- II. Read Opponents Books, Articles, Newspapers, Blogs. Reading Published work. What objections he would raise against the topic and prepare the responses for each of these points.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of opponent Arguments.
- III. Watch Video. Watching Videos of the opponent. What objections he would raise against the topic and prepare the responses for each of these points.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of My own Arguments.
- IV. Listen The recording that the opposition made, in which he addresses these issues.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of My own Arguments.
- V. Talk with People who are students in his class, who can tell me, privately, insights into his thinking and character.
- VI. If that sounds like a lot of work, just say, “I don’t have an opinion on that; why don’t you tell me how you got to have such a firm one? It sounds like I could learn something.”
- VII. Another way to get smarter, outside of reading, is to surround yourself with people who are not afraid to challenge your ideas. “Develop into a lifelong self-learner through voracious reading; cultivate curiosity and strive to become a little wiser every day.”

7. Compound Knowledge- Are The Resources I will Choose Concentrating On the Expiring Information or Compound Knowledge?

- I. Are on the Resources providing expiring information?
 - A. Will you care about what you're reading in a month? In a year? In five years?
 - B. Are you focused enough on the same thing to build cumulative knowledge or are you too spread out?
 - C. What do you spend time on that's likely to change in the next few years? What's not likely to change?
 - D. What would need to happen for you to stop outsourcing organisation of information to the computer?
- II. Signs of The Information in the resources are expiring
 - A. First, it's marketed to you.
 - B. Second, lacking details and nuance, it's easily digestible. This is why it's commonly telling you what happened, not why it happened or under what conditions it might happen again
 - C. Third, it won't be relevant in a month or a year. Expiring information is one reason I stopped reading most news. It's a false map.
- III. While most of us focus on consuming information that we won't care about next month, let alone next year, focus on knowledge and companies that change very, very slowly or not at all. And because the information he was learning changed slowly he could compound his knowledge over time.
- IV. Doing his own thinking and vacuums up the details. When we don't think for ourselves it's easy to put the blame on someone else, to "pass the buck" so to speak.
- V. When we consume information that doesn't expire or expires slowly; is very detailed; and we spend time thinking about it not passing the buck, we can match patterns. This is how you learn to see what other people are missing. The longer you do this, the more advantage you get.
- VI. Just like the rest of us, Buffett's dependent on information and knowledge to make great decisions. Unlike most of us, he has a great memory—perhaps because he's not trying to outsource his memory or thinking to others.
- VII. A lot of what the snowball is about the concept of learning, and creating, and the advantage of having the information and knowing it. When I came here today one

of the things that I was thinking is that what you do is so much at the intersection, because retrieving information is different from having it already in your head.

VIII. What you do is different. You work on manipulating how you use the information.

In fact, Warren Buffett and Charlie Munger have the files in their head. That's why they aren't really out there googling all the time looking for, trying to look stuff up, because they already know it.

IX. I think a lot of the work that you do here is helpful to the ordinary person, but Warren Buffett or Charlie Munger don't need it. At the same time, the lesson that they have, which is that learning yourself, making yourself as smart as you can is extremely valid, and not just relying on a library where you can look something up all the time, because a lot of times when you need to make a decision, and you need 50 pieces of information, you need to know it then.

8. The Art of Anticipation of Objections.

- A. Analyse My Arguments, and Scrutinise The arguments by using Rules of Reading.
- B. Analyse the arguments of the opponent. Scrutinise Their arguments by using Rules of Reading.
- C. Analyse My own arguments. Scrutinise My own arguments, and the potential Loopholes in the argument by Use Rules of Reading.
- D. Use Think, Logic, Strategem, Thinking models.
- E. Write.
- F. Prepare The responses to anticipated objections that, I think the opponent will bring up.
- G. Be intellectually Prepared. This means That I need to know my arguments, so well, that nothing new can surprise me. I would also invest lots of time in knowing and know better opposite side arguments. I would read both side of the arguments, and work Hard on analysing the arguments and evidence of both sides. Doing the work required to hold an opinion means you can argue against yourself better than others can. Only then can you say, "I can hold this view because I can't find anyone else who can argue better against my view." Great thinkers, like Charles Darwin, did the work. And it's one of the biggest reasons he's buried at Westminster Abbey. While we all hold an opinion on almost everything. Have I do the work required to have an opinion on any Subject? Never allow myself to have an opinion on anything that I don't know the other side's argument better than they do. The work required to have an opinion is very hard part, have I avoid it? If that sounds like a lot of work, just say, "I don't have an opinion on that; why don't you tell me how you got to have such a firm one? It sounds like I could learn something."
- H. Doing the work required to hold an opinion means you can argue against yourself better than others can. Only then can you say, "I can hold this view because I can't find anyone else who can argue better against my view." Great thinkers, like Charles Darwin, did the work. And it's one of the biggest reasons he's buried at Westminster Abbey.
- I. Doing the work counteracts our natural desire to seek out only information that confirms what we believe we know. When Darwin encountered opinions or facts that ran contrary to his ideas, he endeavored not only to listen but also not to rest

until he could either argue better than his challengers or understand how the fact fit. Darwin did the work. It's wasn't easy, but that's the point.

- J. Have the best work ethic on daily basis. This is everyday process, and try to figure it out, the strengths and weaknesses of my position and opposing person position, This leads to the True Confidence.
- K. As Per Kobe Bryant statement: Trivial things should not be taken your attention. The attentions should be focused on things that is very important. Anything outside of the most important things in life, you should not have time for. You Should love the challenge in life, and always be curious, if you can be at the top , as these greats in that area. Always focus on one thing and not multiple things, this gives an edge and advantage over other people, who focusing on multiple things in life. The World Becomes a library to you, to be better at your craft.: Everything you see whether TV show I saw, Books, Journals, I read, whether discussion, debate I listen, people I talk to. Everything was done to try to learn to become better at the craft your focusing. When you have this point of view, then the world becomes your library to help you to become better at the craft.
- L. I Always need to ask myself: Have I done the work required to have an opinion on any Subject? Never allow myself to have an opinion on anything that I don't know the other side's argument better than they do. The work required to have an opinion is very hard part, have I avoid it? If that sounds like a lot of work, just say, "I don't have an opinion on that; why don't you tell me how you got to have such a firm one? It sounds like I could learn something."
- M. I might need to Suspend my judgement and tell them that I do not have an opinion on this specific Topic.
- N. Never Under Prepare, but Vastly Over Prepare for the Opponent and their arguments and responses
- O. Spend years in preparation, take debate class at the college or university. You need to participate in debates. You need to have mock debates, where someone play role of your opponent, and then you respond to them. You need to do reading and learn how to flow the debates. How to construct affirmative case and negative case. You need to take time to prepare and have enormous preparation.
- P. Memorize the arguments for my case

9. When Dialogue, Discussion, Debate Takes A Place.

A. As Affirmative Speaker, you need to present Prima Facie Case for proposition that is under debate. Prima Facie Case will be one that will establish the truth of proposition you are defending. If I am defending proposition that God Exist, I will want to give 3-5 arguments leading to that Conclusion, that God Exists, and then I will lay those out with great clarity in my opening speech, and say this is the groundwork for the debate. I am not interested in talking about other issues for example if Christianity bad for society Then, I come back to those in every speech over and over again. The goal is to make opponent argue on your grounds. You do not go over to his grounds, and let your audience forget, your affirmative case, rather you reorganise opponent speech, so that you answer his objections in so far as they reply to your arguments, so you may answer them in a very different order than he gave them, because you will be seeing for example: now what answer or response did he have to the cosmological argument, I see two basic responses and then you deal with them.

- Make Briefs, where I have suitable objection, and then have two or three responses to those objections.
- Use The Brief During Exchange with the Opponent. File these Briefs into Folders, and spread These Manila Folders out in front of me on Desk, When I am interacting with the Opponent. Once the opponent Rises his point I just pull These briefs from these folders and never have to think on my feet because I am completely prepared. Key is never have to think on the feet to be so well prepared, that I would have my responses ready for anything he brings up.
- Quote Peer Review Scientific Articles on the topic in support the conclusions.

B. Take Notes While the Opposition is speaking:

- How To Take Notes- Flow Chart. By Taking Notes, I am sure that I am responding to my opponent's arguments and everything he brings up.

I. Make 11-12 Columns on the Pad. Prepare the left column in advance of the communication, debate. The Left Column needs to be filled in, if you starting first. If not, then leave left column as blank.

II. First Left Hand Column Are My Arguments.

III. Second Left Hand Column are Opposition Arguments and Responses to My arguments.

IV. Third Left Column are My Responses to the Opponent responses.

V. Fourth Left Hand Column are My Rebuttal.

VI. Fifth Left Hand Column are Opponent Rebuttal.

VII. Sixth Left Hand Column are my Responses to the Opponent rebuttal.

VIII. Seventh Left Hand Column is the Final My Rebuttal.

IX. Eight Left Hand Column is The opponent Rebuttal.

X. Ninth Left Hand Column is my closing statements.

XI. Tenth Left Hand Column is the opponent closing statements.

XII. Eleventh Left Hand Column is the Cross Examination.

- My Answer.

- Opponent Answer.

- My response to the response of the opponent.

C. Always Remind the audience what are your three to five arguments and what are the responses of the opponent, if any to your arguments.

D. Always allow the opponent allow to lay out his argument without interruption.

E. Take the opponent arguments and put in my own words and correctly represent their argument carefully without misrepresentation.

F. Be Honest.

G. Be Open Minded.

H. Always from Your side be honest and rigorous exchange of arguments and counter Arguments from which me and opponent would benefit.

I. One of good technique is whenever you can quote an opponent against himself, this is powerful device. Have the manuscript, point to the footnote, cite the book, and the quotation and have the page number.

J. Never Take Cheap Shots at the Opponent.

- K. Encourage not just trust someone say so, but demand published peer reviewed articles in support of the positions that one take
- L. Always look at the reality of the situation, and do not let the emotion cloud the situation and the execution. Always be in the present and the moment.

Step 114-Use Rules of Reading for Strategy and Tactics

1. Listen, Follow and Apply Rules of Reading of Bible Study, Deep Work, Deep Study, Analysis, Syntopicon and Research For Strategy and Tactics.
 - A. **VERY VERY FAST Reading- Skimming. Pages 47-51.**
 - B. **VERY FAST READING- Entertainment.**
 - I. **Method 1-Speed Reading. FAST Reading. Pages 59-64.**
 - C. **FAST READING: Methods for Basic Knowledge For Deep Work or Bible Study.**
 - I. **Method 1-Survey, Question, Read, Recite, Record, Reflect (SQR4). Pages 66-67.**
 - II. **Method 2-Use 80/20 Principle For Reading. Pages 68.**
 - III. **Method 3-Preview, Question, Read, Summary,Test (PQRST). Page 69.**
 - IV. **Method 4-Flip Through Pages and Analyse. Page 70.**
 - V. **Method 5-Devotional Bible Study by Using Devotional Books. Pages 71-72.**
 - VI. **Method 6-Devotional Bible Read. Pages 73-74.**

D. Deep Work, Deep Study, Bible Study or Any Book- SLOW Reading- Complex Text.

- I. Method 1-Chapter Summary Method. Pages 143-147.**
- II. Method 2-Character Quality Method. Pages 148-160.**
- III. Method 3-Thematic Method. Pages 161-163.**
- IV. Method 4-Biographical Method. Pages 164-176.**
- V. Method 5-Topical Method. Pages 177-180.**
- VI. Method 6-Word Study Method. Pages 181-189.**
- VII. Method 7-Book Background Method. Pages 190-194.**
- VIII. Method 8-Book Survey Method. Pages 195-205.**
- IX. Method 9-Chapter Analysis Method. Pages 206-215.**
- X. Method 10-Paragraph Study. Pages 216-229.**
- XI. Method 11-Verse by Verse Analysis Method. Pages 230-234.**
- XII. Method 12-Book Synthesis Method. Pages 235-238.**
- XIII. Method 13-Theological Study Method of Bible Study. Pages 239-245.**
- XIV. Method 14-Studying Bible Prophecy. Pages 246-259.**
- XV. Method 15-Typological Study Method. Pages 260-262.**
- XVI. Method 16- John MacArthur Way Bible Study. Pages 263-268.**
- XVII. Method 17-Inductive Bible Study Method. Pages 269-296.**
- XVIII. Method 18-BIBLICAL HERMENEUTICS. Pages 297-302.**
- XIX. Method 19-Theological Group of Principles. Pages 303-306.**
- XX. Method 20- How To Read A Book Pages 307.**

E. VERY VERY SLOW READING- COMPLEX TEXT. Deep Work, Shallow Work, Bible Study, Analysis of Text, Research, Investigative Journalism, Investigation and Syntopicon, Mixed Method.

- I. Method 21- How To Read A Book By Mortimer Adler Various edition Pages 341.**
- II. Method 22-How To Read A Book For Various Books. Pages 342-600.**
- III. Method 23- Syntopicon Pages 601-642.**
- IV. Method 24-The Craft of Research. Pages 644-882.**
- V. Method 25-Research Books can Be Used. Pages 883-897.**
- VI. Method 26-Investigative Journalism. Pages 898-923.**
- VII. Method 27-Mixed Methods of Rules of Reading. Pages 924-942.**

2. Apply The Books To Strategy and Tactics

Step 115-Strategy, Stratagem and Tactic

Books

1. **Listen, Follow And Apply Rules of Reading Part 1 to 14, before looking into Strategy and Tactics.**
2. **Listen, Follow and Apply the following Books.**
 - A. Competitive Strategy.
 - B. Games, Strategies, and Decision Making.
 - C. Good Strategy_Bad Strategy.
 - D. Strategic Management_ Theory & Cases_ An Integrated Approach.
 - E. The 33 Strategies of War.
 - F. The Art of Strategy_ A Game Theorist's Guide to Success in Business and Life.
 - G. Your Strategy Needs a Strategy_ How to Choose and Execute the Right Approach.
 - H. 36 Strategem.
 - I. Extreme Ownership.
 - J. Competitive Advantage of Nations.
 - K. Competitive advantage_ creating and sustaining superior performance _ with a new introduction.
 - L. Chinese Stratagem and Chinese Business Negotiating Behaviour: An Introduction.
 - M. Secrecy & Stratagem_ Understanding Chinese Strategic Culture.
 - N. Stratagem_ Deception and Surprise in War (Artech House Information Warfare Library).
 - O. Stratagems And Spoils_ A Social Anthropology Of Politics.
 - P. Strategem.
 - Q. Strategic Management.
 - R. Strategic Management.
 - S. Strategic Management and Business Policy.
 - T. Strategic Management Theory An Integrated Approach.
 - U. Strategy - Strategic Planning For Project Management.
 - V. Sun Tzu and the Art of Business_ Six Strategic Principles for Managers.

- W. The 33 Strategies of War.
- X. The 36 Stratagems for Business_ Achieve Your Objectives Through Hidden and Unconventional Strategies and Tactics.
- Y. The 36 Strategies of the Chinese Can It Be a Eurasian Strategic Model in a Global Context?
- Z. The 36 strategies of the martial arts _ the classic Chinese guide for success in war, business, and life.
- AA.The Art of War for Small Business_ Defeat the Competition and Dominate the Market with the Masterful Strategies of Sun Tzu.
- BB.The Art of War_ Complete Text and Commentaries.
- CC.The Attacker's Advantage_ Turning Uncertainty into Breakthrough Opportunities.
- DD.The Complete Art of War.
- EE.Treasons, Stratagems, And Spoils_ How Leaders Make Practical Use Of Beliefs And Values.

Step 116-A Primer on Strategy

There are many good reasons to read Good Strategy Bad Strategy by Richard Rumelt.

You may be frustrated by the state of your organization's strategy. You may be interested in identifying the characteristics of good strategy. Or you may want to learn how to identify the elements of a bad strategy.

A leader's most important responsibility is identifying the biggest challenges to forward progress and devising a coherent approach to overcoming them. In contexts ranging from corporate direction to national security, strategy matters. Yet we have become so accustomed to strategy as exhortation that we hardly blink an eye when a leader spouts slogans and announces high-sounding goals, calling the mixture a "strategy."

Complexity

"A hallmark of mediocrity and bad strategy," Rumelt writes, "is unnecessary complexity—a flurry of fluff masking an absence of substance." Most bad strategies are nothing more than statements of desire. And if you read them closely, the goals often contradict one another. This book should be required reading for managers and executives alike.

The Strategy Retreat

I'm sure this excerpt sounds familiar to many of you:

The event was a "strategy retreat." The CEO had modeled it on a similar event at British Airways he had attended several years before. About two hundred upper-level managers from around the world gathered in a hotel ballroom where top management presented a vision for the future: to be the most respected and successful company in their field. There was a specially produced motion picture featuring the firm's products and services being used in colorful settings around the world. There was an address by the CEO accompanied by dramatic music to highlight the company's "strategic" goals: global leadership, growth, and high shareholder return. There were breakouts into smaller groups to allow discussion and buy-in. There was a colorful release of balloons. There was everything but strategy.

Good strategy is the exception not the rule. Rumelt argues that the bad strategy problem is only growing. Even worse, more and more leaders think they have a strategy when they do not—they have a bad strategy. Bad strategy, "ignores the power of choice and focus,

trying instead to accommodate a multitude of conflicting demands and interests.” Sounds familiar?

What is a bad strategy?

Bad strategy is long on goals and short on policy or action. It assumes that goals are all you need. It puts forward strategic objectives that are incoherent and, sometimes, totally impracticable. It uses high-sounding words and phrases to hide these failings.

Underperformance

When a leader characterizes the challenge as underperformance, it sets the stage for bad strategy. Underperformance is a result. The true challenges are the reasons for the underperformance.

Good Strategy

Good strategy is not just “what” you are trying to do. It is also “why” and “how” you are doing it. ... Good strategy requires leaders who are willing and able to say no to a wide variety of actions and interests. Strategy is at least as much about what an organization does not do as it is about what it does.

Strategy is not vision or ambition

Despite the roar of voices wanting to equate strategy with ambition, leadership, “vision,” planning, or the economic logic of competition, strategy is none of these. The core of strategy work is always the same: discovering the critical factors in a situation and designing a way of coordinating and focusing actions to deal with those factors. A leader’s most important responsibility is identifying the biggest challenges to forward progress and devising a coherent approach to overcoming them. In contexts ranging from corporate direction to national security, strategy matters.

The Three Elements of Strategy

The kernel of a strategy contains three elements: a diagnosis, a guiding policy, and coherent action. The guiding policy specifies the approach to dealing with the obstacles called out in the diagnosis. It is like a signpost, marking the direction forward but not defining the details of the trip. Coherent actions are feasible coordinated policies, resource commitments, and actions designed to carry out the guiding policy.

Coherence of design

A good strategy doesn’t just draw on existing strength; it creates strength through the coherence of its design. Most organizations of any size don’t do this. Rather, they pursue

multiple objectives that are unconnected with one another or, worse, that conflict with one another.

Coordination is costly and hard

Coordination is costly, because it fights against the gains to specialization, the most basic economies in organized activity. To specialize in something is, roughly speaking, to be left alone to do just that thing and not be bothered with other tasks, interruptions, and other agents' agendas. As is clear to anyone who has belonged to a coordinating committee, coordination interrupts and de-specializes people.

Good strategy is surprising

Most complex organizations spread rather than concentrate resources, acting to placate and pay off internal and external interests. Thus, we are surprised when a complex organization, such as Apple or the U.S. Army, actually focuses its actions. Not because of secrecy, but because good strategy itself is unexpected.

Focus, however, is hard. It means saying no to individuals, groups, and even entire lines of business.

The inside view describes the fact that people tend to see themselves, their group, their project, their company, or their nation as special and different.

Increasing value ...

In particular, increasing value requires a strategy for progress on at least one of four different fronts: deepening advantages, broadening the extent of advantages, creating higher demand for advantaged products or services, or strengthening the isolating mechanisms that block easy replication and imitation by competitors.

Unfinished Thought

As I was reading this book I kept wondering why organizations were so reluctant to employ a strategy. All of this thinking reminded me of another book I had read a few years back on strategy called The Strategy Paradox.

What is the paradox?

The most profitable strategies are “extreme” strategies that commit companies to positions of either product differentiation or cost leadership. These extreme positions expose firms to a greater likelihood of bankruptcy by increasing the strategic risk they face. Consequently, the strategies likeliest to succeed are also likeliest to fail. That is the strategy paradox.

At first I thought that maybe organizations avoided good strategy simply because it was complicated and involved hard choices. The more I thought about it, however, the more I settled on the fact that people avoid good strategies because they don't want to be wrong. When Steve Jobs took over Apple, he did the unexpected.

What he did was both obvious and, at the same time, unexpected. He shrunk Apple to a scale and scope suitable to the reality of its being a niche producer in the highly competitive personal computer business. He cut Apple back to a core that could survive.

Steve Jobs talked Microsoft into investing \$150 million in Apple, exploiting Bill Gates's concerns about what a failed Apple would mean to Microsoft's struggle with the Department of Justice. Jobs cut all of the desktop models—there were fifteen—back to one. He cut all portable and handheld models back to one laptop. He completely cut out all the printers and other peripherals. He cut development engineers. He cut software development. He cut distributors and cut out five of the company's six national retailers. He cut out virtually all manufacturing, moving it offshore to Taiwan. With a simpler product line manufactured in Asia, he cut inventory by more than 80 percent. A new Web store sold Apple's products directly to consumers, cutting out distributors and dealers.

What is remarkable about Jobs's turnaround strategy for Apple was how much it was “Business 101” and yet how much of it was unanticipated.

In May 1998, shortly after taking over Apple, Jobs explained the substance and coherence of his actions:

The product lineup was too complicated and the company was bleeding cash. A friend of the family asked me which Apple computer she should buy. She couldn't figure out the differences among them and I couldn't give her clear guidance, either. I was appalled that there was no Apple consumer computer priced under \$2,000. We are replacing all of those desktop computers with one, the Power Mac G3. We are dropping five of six national retailers—meeting their demand has meant too many models at too many price points and too much markup.

Jobs's actions were both focused and decisive and, in hindsight, correct. Everyone at the time was surprised because they expected the fluffy goals and vacuous promises typical of

most executives. But Jobs's back-to-business 101 approach was correct. Jobs had a sick business and he needed to fix it.

While Jobs's turnaround at Apple was impressive it wouldn't enable Apple to become more than a niche player in an industry dominated by network effects. In 1998 Rumelt had a chance to ask Jobs "What is the strategy?" Jobs responded simply "I am going to wait for the next big thing." This encounter struck Rumelt as different. Everywhere he went and everyone he talked to just spewed the same clichés about their strategy — network relationships, adopt best practices, etc.

Rumelt writes:

Jobs did not enunciate some simple-minded growth or market share goal. He did not pretend that pushing on various levers would somehow magically restore Apple to market leadership in personal computers. Instead, he was actually focused on the sources of and barriers to success in his industry—recognizing the next window of opportunity, the next set of forces he could harness to his advantage, and then having the quickness and cleverness to pounce on it quickly like a perfect predator. There was no pretense that such windows opened every year or that one could force them open with incentives or management tricks. He knew how it worked. He had done it before with the Apple II and the Macintosh and then with Pixar. He had tried to force it with NeXT, and that had not gone well. It would be two years before he would make that leap again with the iPod and then online music. And, after that, with the iPhone.

Steve Jobs's answer that day—"to wait for the next big thing"—is not a general formula for success. But it was a wise approach to Apple's situation at that moment, in that industry, with so many new technologies seemingly just around the corner.

In hindsight we know Jobs's strategy worked but it could have just as easily backfired. The turnaround might have failed and landed Apple, now the world's largest company, in bankruptcy. Apple's strategy at the time wasn't easy to like — in fact, many people thought he was wrong. I imagine that Jobs would have been ok with being wrong — he was more worried about being mediocre.

We equate strategy with success but they are different things.

Real strategies—*good strategies*—can be wrong. And we don't want to be wrong. We're playing not to lose rather than playing to win. We all know how it feels to make a mistake — we'd rather watch other people make mistakes than make them ourselves. So we seek consensus because it's safe.

Yet consensus, when you think about it, is almost assured to fail. It's making everyone happy and alienating no one.

Consensus is the opposite of marshalling your resources towards a coordinated approach. And consensus, by definition, almost certainly assures a bad strategy because it doesn't make any choices. It's a sprinkle of this and a dash of that — it's something for everyone. Rather than risk being wrong, we hide behind puff that makes everyone happy. That's bad strategy.

The beauty of Good Strategy Bad Strategy is that it calls out the vast majority of public and private organizations that have horrible strategies. The bad news is that things are unlikely to change. After all, no one ever got fired for having a strategy to "increase the percentage of high school graduates." It's hard to argue with that as a goal but let's stop calling it a strategy.

There are plenty of good strategies out there. Lou Gestner developed one when he took over IBM in 1993 (for details see Gestner's book — Who Says Elephants Can't Dance?: Leading a Great Enterprise through Dramatic Change). He understood the problem and devised an approach that marshalled the organization towards dealing with the problem.

Step 117-Strategy vs. Tactics: Why the Difference Matters

In order to do anything meaningful, you have to know where you are going.

Strategy and tactics are two terms that get thrown around a lot, and are often used interchangeably in numerous contexts. But what exactly do they mean, what is the difference, and why is it important? In this article, we will look at the contrast between strategy and tactics, and the most effective ways to use each.

While strategy and tactics originated as military terminology, their use has spread to planning in many areas of life. Strategy is overarching plan or set of goals. Changing strategies is like trying to turn around an aircraft carrier—it can be done but not quickly. Tactics are the specific actions or steps you undertake to accomplish your strategy. For example, in a war, a nation's strategy might be to win the hearts and minds of the opponent's civilian population. To achieve this they could use tactics such as radio broadcasts or building hospitals. A personal strategy might be to get into a particular career, whereas your tactics might include choosing your educational path, seeking out a helpful mentor, or distinguishing yourself from the competition.

We might have strategies for anything from gaining political power or getting promoted, to building relationships and growing the audience of a blog. Whatever we are trying to do, we would do well to understand how strategy and tactics work, the distinction, and how we can fit the two together. Without a strategy we run the risk of ambling through life, uncertain and confused about if we are making progress towards what we want. Without tactics, we are destined for a lifetime of wishful thinking or chronic dissatisfaction. As Lawrence Freedman writes in *Strategy: A History*, "Without a strategy, facing up to any problem or striving for any objective would be considered negligent. Certainly, no military campaign, company investment, or government initiative is likely to receive backing unless there is a strategy to evaluate.... There is a call for strategy every time the path to a given destination is not straightforward." And without tactics you become dependent on pure luck to implement your strategy.

To achieve anything we need a view of both the micro and the macro, the forest and the trees—and how both perspectives slot together. Strategy and tactics are complementary. Neither works well without the other. Sun Tzu recognized this two and a half millennia ago

when he stated, “Strategy without tactics is the slowest route to victory. Tactics without strategy are the noise before defeat.” We need to take a long-term view and think ahead, while choosing short-term steps to take now for the sake of what we want later.

The Relationship Between Strategy and Tactics

Any time we decide on a goal and invest resources in achieving it, we are strategizing. Freedman writes:

One common contemporary definition describes it as being about maintaining a balance between ends, ways, and means; about identifying objectives; and about the resources and methods available for meeting such objectives. This balance requires not only finding out how to achieve desired ends but also adjusting ends so that realistic ways can be found to meet them by available means.

In *The Grand Strategy of the Roman Empire*, Edward N. Luttwak writes that strategy “is not about moving armies over geography, as in board games. It encompasses the entire struggle of adversarial forces, which need not have a spatial dimension at all....” When you think about winning a war, what does it mean to actually win? History is full of examples of wars that were “won” on paper, only to be restarted as soon as the adversary had time to regroup. So being precise in your goal, to encompass the entirety of what you want to achieve, is necessary to articulate a good strategy. It’s not about success in the moment, but success in the long term. It’s the difference between the end of WWI and WWII. World War I was about winning that war. World War II was about never fighting a war like that again. The strategies articulated and pursued by the Treaty of Versailles and the Marshall Plan were full of markedly different tactics.

In *Good Strategy, Bad Strategy*, Richard Rumelt writes: “The most basic idea of strategy is the application of strength against weakness. Or if you prefer, strength applied to the most promising opportunity...A good strategy doesn’t just draw on existing strength; it creates strength.” Rumelt’s definition of strategy as creating strength is particularly important. You don’t deplete yourself as you execute your strategy. You choose tactics that reinforce and build strength as they are deployed. Back to winning hearts and minds – the tactics require up-front costs. But as they proceed, and as the strategy unfolds, strength and further support are gained by having the support of the local population. A good strategy makes you stronger.

“Grand strategy is the art of looking beyond the present battle and calculating ahead. Focus on your ultimate goal and plot to reach it.”

— Robert Greene, *The 33 Strategies of War*

The Components of Strategy

The strategic theorist Henry Mintzberg provides a useful approach to thinking about strategy in adversarial situations. According to Mintzberg, there are five key components or types:

1. Plan: A consciously chosen series of actions to achieve a goal, made in advance.
2. Ploy: A deliberate attempt to confuse, mislead or distract an opponent.
3. Pattern: A consistent, repeated series of actions that achieve the desired result.
4. Position: A considered relationship between an entity (organization, army, individual etc) and its context.
5. Perspective: A particular way of viewing the world, a mindset regarding actions that lead to a distinct way of behaving.

Geoffrey P. Chamberlain offers a slightly different perspective on the components of strategy, useful when the strategy is more about a personal goal. He identifies seven parts:

1. A strategy is used within a particular domain.
2. A strategy has a single, well defined focus.
3. A strategy lays out a path to be followed.
4. A strategy is made up of parts (tactics).
5. Each of a strategy's parts pushes towards the defined focus.
6. A strategy recognises its sphere of influence.
7. A strategy is either intentionally formed or emerges naturally.

According to Rumelt, a strategy must include “premeditation, the anticipation of others’ behavior, and the purposeful design of coordinated actions. As a general rule, strategy is more important in situations where other parties have the potential to thwart or disrupt actions, or where our plans are at risk if we don’t take meaningful steps to achieve them. Good strategy requires us to both focus on a goal, and anticipate obstacles to reaching that goal. When we encounter obstacles, we may need to employ what Freedman calls “deceits, ruses, feints, manoeuvres and a quicker wit”—our tactics.

“The skillful tactician may be likened to the Shuai-Jan. Now the Shuai-Jan is a snake that is found in the Ch’ang mountains. Strike at its head, and you will be attacked by its tail; strike at its tail, and you will be attacked by its head; strike at its middle, and you will be attacked by head and tail both.”

— Sun Tzu, The Art of War

A Few Words on Tactics

Even the most elegant, well-planned strategy is useless if we do not take thoughtful steps to achieve it. While the overall goal remains stable, the steps we take to achieve it must be flexible enough to adjust to the short-term realities of our situation.

The word “tactic” comes from the Ancient Greek “taktikos,” which loosely translates to “the art of ordering or arranging.” We now use the term to denote actions toward a goal. Tactics often center around the efficient use of available resources, whether money, people, time, ammunition, or materials. Tactics also tend to be shorter-term and more specific than strategies.

Many tactics are timeless and have been used for centuries or even millennia. Military tactics such as ambushes, using prevailing weather, and divide-and-conquer have been around as long as people have fought each other. The same applies to tactics used by politicians and protesters. Successful tactics often include an ‘implementation intention’—a specific trigger that signals when they should be used. Simply deciding what to do is rarely enough. We need an “if this, then that” plan for where, when and why. The short-term nature and flexibility of tactics allow us to pivot as needed, choosing the right ones for the situation, to achieve our larger, strategic goals.

If you don't have a strategy, you are part of someone else's strategy.”

— Alvin Toffler

Conclusion

Although often regarded as interchangeable, strategy and tactics are somewhat different, though complementary concepts. According to the skilled strategist Sun Tzu, strategy is about winning before the battle begins, while tactics are about striking at weakness. Both are ancient concepts that have come to be an essential part of numerous disciplines and offer endless new ways of thinking.

Step 118 Thinking, Logic and Mental Model

1. Listen, Follow and Apply Thinking, Logic and Mental Model PART 7

Part 7: Thinking, Logic and Mental Model For Deep Work or Deep Study, Or Bible Study

- 1. Step 57- Slow Down. Pages 1061-1063.**

Step 119- Tiny Gains. Massive Results.

When we want to improve ourselves, we often pursue dramatic changes with little success. A better idea is to go for small, incremental improvements that add up over time.

Self-motivated, self-starting individuals are incredibly motivated to find their weaknesses. It's not far-fetched to say that some of us actually seek to make ourselves perfect — rational, calculating beings making the right type of decisions at just the right times. But we've learned from Star Trek; we don't look to eliminate emotion either and turn ourselves into Mr. Spock. We want *just the right amount* of emotion in our lives.

People often overestimate what they can accomplish in one year. But they greatly underestimate what they could accomplish in five years.

— Peter drucker

If we're night owls, we seek to become early risers. (Ben Franklin did it!). If we're procrastinators, we look to become doers. If we're always late to meetings, we look to be early to meetings. We want to eliminate our weaknesses and become a little More.

This is, of course, a laudable goal. But the self-starters among us have probably all run into the same problem: We don't actually follow through on the things we know will make us better. We don't eat the broccoli. We get a little too robotic. We get up at 8:30 when we said we'd do 5:30 from here on out. We leave that essay until the last second even though that was never going to happen again. We're five minutes late. We don't become lore at all, and the failure to get there makes us feel like less.

The culprit is the thought that any important change happens quickly. It doesn't matter whether you're trying to get up early or pick up and implement the Psychology of Human Misjudgment. Anything important happens slowly.

From Potential to Useful

And why should it be otherwise? If you were to truly understand, in-depth, and apply the *Psychology of Human Misjudgment* to your dealings, you'd be way far out ahead of your peers and your former self. The advantage of understanding human nature is incredible. But it takes deep, repeated study and a long gestation period to get there. It takes applying the ideas to the world, feeling them out, forgetting them, redoubling yourself, and trying again. Not giving up when you forget or fail. It is through the process of *refinement* that one learns new habits and ideas.

The visual mental model I like for self-improvement is imagining something like a Lathe.

A *lathe*, for the non-engineer, is a tool that molds a piece of material into some shapely form. A machinist would use a lathe to take a hunk of metal and turn it into a usable engine part, for example. The lathe takes something with *potential* and shapes it into something *useful* by slowly refining it and shaving away the excess.

Compounding works in other areas besides money.

The way I think about it, if I can get 5% wiser and better every year, then I will be about twice as wise as I am now in less than 15 years. (Go ahead, grab your calculators.) In less than 30 years, my return will be 4x. This is how the non-gifted among us can surpass otherwise more intelligent people.

Tiny Improvements, Massive Results

Tiny improvements add up to *massive* differences.

Compounding works in other areas besides money. And we want to compound worldly wisdom. These little mental tricks like the Lathe and the idea of 5% yearly improvement are just ways to remind myself that I'm not going to wake up wiser/nicer/healthier/smarter tomorrow morning or the morning after. And just as importantly, if I backslide on a goal I've set or I forget something I thought I'd learned well, that it's really not the end of the world. I don't need to give up and call it hopeless. All I have to do is figure out where I slipped, re-double my efforts, and go after it again. All I need is 5% a year to become 4x better in my adult lifetime. The truth is that whatever bad habits you have or whatever things you're struggling to learn, there's probably a good reason. Your biology and your experiences to date have set you in stone to a certain extent, and the older you are, the more likely that is to be true. The chains of habit are too light to be felt until they are too heavy to be broken. Billion-dollar industries have been built on convincing you that it's *easy* to make big changes or to get a lot wiser and better. But it honestly isn't. It's hard work.

Yet any study of great individuals reveals that the work is worth doing.

So just imagine if you could make slightly better decisions every year. Whether it's 5% better consideration of *all* of your decisions, or making 5% of your decisions differently, or some permutation thereof, it doesn't really matter. Every year you'll look back at some part of your old self and wonder how you could've been so dumb. And one day, in less than 30 years, you'll look back and see your old self as almost unrecognizably stupid.

What more could you ask for?

Step 120-Letting The World Do The Work For You

1. Listen and Apply book
 - I. This Explains Everything_ Deep, Beautiful, and Elegant Theories of How the World Works
2. **The world never tells you that you're wrong; it only gives you outcomes.**
3. **Don't force. Don't resist. Have a beginner's mind. Let the world teach you.**
4. **Reality will do a lot of the work for us if we simply align with it. Most of the time we're simply adding friction because we want the world to work in the way we think it should.**
5. **If you don't see the world the way it is, you'll think it works in a way that it doesn't and make terrible mistakes. The key to getting what you want out of life is to identify how the world works and align yourself accordingly. This is hard because we think the world should work the way we see it. The word "should" is important. Because we think the world should work in a way that it doesn't, our approach is suboptimal. What the pupil must learn, if he learns anything at all, is that the world will do most of the work for you, provided you cooperate with it by identifying how it really works and aligning with those realities. If we do not let the world teach us, it teaches us a lesson. Joseph Tussman**
6. When an outcome is not what you want it to be, things get tough. You can ignore the result and continue to think that you're right. This protects your ego. It also carries the risk of your continuing to believe something that isn't true. Alternatively, you can calibrate your believability on the subject at hand by lowering the odds that you're right. For example, maybe you gave yourself an 85 out of 100 for the ability to hold a firm opinion on this subject, and now you lower your score to 75. If the world continues to provide undesirable outcomes, eventually you get the hint and change your beliefs. Finally, you can give up your opinions and just respond to the world as it is. This option is the hardest.
7. You do not create the way the world works, you can only align yourself with it. It takes a lot of work to align ourselves with reality. When we don't get the outcome we're seeking, the last place we look is inside ourselves. Instead, we blame others or

circumstances. If you want to align yourself with reality, you have to work at it and care about it. There are two keys to aligning yourself with how the world really works: accepting feedback and stopping bargaining.

- I. We let people, not results, guide our behavior. The world tries to tell us when we don't see it the way it is. The problem is we don't listen to the world. Instead, we let others tell us what's right and wrong, what works, and what doesn't. Common actions get common results. Most of our actions come from others. We want what they want. Even worse, we employ the same actions to get it. This isn't always wrong. If you're just starting, the quickest path to average is to copy. If you want better results than average, you're going to have to iterate. Doing something different means we might look like a fool, and we do not want to look like a fool. Iterating means trying something new, it means you might fail. Show me a person who's afraid to look bad, and I'll show you a person you can beat every time. If we do what everyone else is doing, we're going to get the same results that everyone else is getting. Different results demand different actions. If you can't really fail, you can't really succeed. Let results, not popularity, determine your actions. If you're doing something that doesn't get you the results you want, try something new. If you're doing something that seems to work, keep doing it. Consistently repeat successful actions.
- II. Bargaining with the world doesn't work. A lot of otherwise smart people know what they're doing isn't getting the results they want, but because they think the world *should* work in a way that it doesn't, they keep repeating them hoping for different results. If you are this person, see it for what it is, and change your actions. The feedback from the world is often painful. Often, it is this very pain that causes us to no longer delude ourselves with how the world should work and accept how it does work. If you can learn to accept the world for how it is, before suffering, you'll go faster and further. Outcome over ego. If you think you know how the world works but you're doing something that gets suboptimal results because it *should* work a different way, you don't really know how the world works. Rational people take feedback from the world. If you want to know how someone sees the world, look at their actions. In the end, it's all your fault. You are accountable for your outcomes. When you take responsibility for your outcomes, you naturally accept feedback from reality. When you get feedback from reality, you adjust your behavior.

- III. As Per Kobe Bryant statement: Trivial things should not be taken your attention. The attentions should be focused on things that is very important. Anything outside of the most important things in life, you should not have time for. You Should love the challenge in life, and always be curious, if you can be at the top , as these greats in that area. Always focus on one thing and not multiple things, this gives an edge and advantage over other people, who focusing on multiple things in life. The World Becomes a library to you, to be better at your craft.: Everything you see whether TV show I saw, Books, Journals, I read, whether discussion, debate I listen, people I talk to. Everything was done to try to learn to become better at the craft your focusing. When you have this point of you, then the world becomes your library to help you to become better at the craft.
- IV. Have the best work ethic on daily basis. This is everyday process, and try to figure it out, the strengths and weaknesses of my position and opposing person position.
- V. Always look at the reality of the situation, and do not let the emotion cloud the situation and the execution. Always be in the present and the moment.
- VI. If you understand the world as it really is, not as you'd wish it to be, you will begin to make better decisions almost immediately. Once you start making better decisions the results compound. Better initial decisions free up your time, reduce your stress, allowing you to spend more time with your family and leave your competition in the dust.
- VII. How can we best understand the world as it is? Acquiring knowledge can be a very daunting task. If you think of the mind as a toolbox, we're only as good as the tools at our disposal. A carpenter doesn't show up to work with an empty toolbox. Not only do they want as many tools in their toolbox as possible, but they want to know how to use them. Having more tools and the knowledge of how to use them means they can tackle more problems. Try as we might, we cannot build a house with only a hammer. If you're a knowledge worker, you're a carpenter. But your tools aren't bought at a store and they don't come in a red box that you carry around. Mental tools are the big ideas from multiple disciplines, and we store them in our mind. And if we have a lot of tools and the knowledge required to wield them properly, we can start to synthesize how the world works and make better decisions when confronted with problems.
- VIII. This is how we understand and deal with reality. The tools you put into your toolbox are Mental Models. Mental models are a framework for understanding

how the world really works. They help you grasp new ideas quickly, identify patterns before anyone else and shift your perspective with ease. Mental Models allow us to make better decisions, scramble out of bad situations, and think critically. If you want to understand reality you must look at a problem in multiple dimensions — how could it be otherwise? Getting to this level of understanding requires having a lot of tools and knowing how to use them. You knew there was a hitch right? We need to change our fast-food diet of information consumption and adopt the healthier diet of knowledge that changes slowly over time. While changing diets isn't easy, it can be incredibly rewarding: more time, less stress, and being better at your job. The costs, however, are short term pain for long-term gain. You must change how you think.

- IX. 2nd Order Thinking. One example of a model we can immediately conceptualize and use to improve our ability to make better decisions is something we can borrow from ecology called second-order thinking. The simple way to conceptualize this is to ask yourself "If I do X, what will happen *after* that?". I sum this up using the ecologist Garrett Hardin's simple question: "And then what?" A lot of people forget about higher order effects — second and third-order effects or higher. I've been in a lot of meetings where decisions are made and very few people think to the second level, let alone the third. Rather, what typically happens is called first conclusion bias. The brain shuts down and stops thinking at the first idea that comes to mind that seems to address the problem as you understand it. We don't often realize that our first thoughts are usually not even our own thoughts. They usually belong to someone else. We understand the sound-byte but we haven't done the hard work of real thinking. After we reach the first conclusion, our minds often shut down. We don't seek evidence that would contradict our conclusion. We don't ask ourselves what the likely result of this solution would be — we don't ask ourselves "And then what?" We don't ask what other solutions might be even *more* optimal. For example, consider a hypothetical organization that decides to change their incentive systems. They come up with a costly new system that requires substantial changes to the current system. Only they don't consider (or even understand) the problems that the *new* system is likely to create. It's possible they've created more problems than they've solved — only now there are *different* problems they must put their head down to solve. Optically, they "reorganize their incentive programs," but practically, they've simply expended energy to stay in place. Another, perhaps more complicated,

example is when a salesman comes into a company and offers you a software program he claims will lower your operating costs and increase your profits. He's got all these beautiful charts on how much more competitive you'll be and how it will improve everything. This is exactly what you need because your compensation is based on increasing profits. You're sold. Then second-order thinking kicks in and you dare to ask how much of those cost savings are going to go to you and how much will eventually end up benefits enjoyed by customers? To a large extent, that depends on the business you're in. However, you can be damn sure the salesman is now knocking on your competitor's door and telling them you just bought their product and if they want to remain competitive they better purchase it too. Eventually, you all have the new software and no one is truly better off. Thus, in the manner of a crowd of people standing on their tip-toes at a parade, all competitors spend the money but none of them win: The salesman wins and the customer wins. We know, thanks to people like Garrett Hardin, Howard Marks, Charlie Munger, Peter Kaufman, and disciplines like ecology, that there are second and third-order effects. This is how the world really works. It just isn't always a comfortable reality. Understanding how the world works isn't easy and it shouldn't be. It's hard work. If it were easy, everyone would do it. And it's not for everyone. Sometimes, if your goal is to maximize utility, you should focus on getting very, very good in a narrow area and becoming an expert, accepting that you will make many mistakes outside of that domain. But for most, it's extremely helpful to understand the forces at play outside of their narrow area of expertise. Because when you think about it, how could reality be anything other than a synthesis of multiple factors? How could it possibly be otherwise?

- X. When our mental models line up with reality, they help us avoid problems. However, they also cause problems when they don't line up with reality as we think something that isn't true.
- XI. We must be open to other perspectives if we truly want to understand the results of our actions. Despite feeling that we've got all the information, if we're on the ship, the fish in the ocean has more he can share. The second flaw is ego. Many of us tend to have too much invested in our opinions of ourselves to see the world's feedback—the feedback we need to update our beliefs about reality. This creates a profound ignorance that keeps us banging our head against the wall over and over again. Our inability to learn from the world because of our ego happens for many reasons, but two are worth mentioning here. First, we're so

afraid about what others will say about us that we fail to put our ideas out there and subject them to criticism. This way we can always be right. Second, if we do put our ideas out there and they are criticized, our ego steps in to protect us. We become invested in defending instead of upgrading our ideas. The third flaw is distance. The further we are from the results of our decisions, the easier it is to keep our current views rather than update them. When you put your hand on a hot stove, you quickly learn the natural consequence. You pay the price for your mistakes. Since you are a pain avoiding creature, you update your view. Before you touch another stove, you check to see if it's hot. But you don't just learn a micro lesson that applies in one situation. Instead, you draw a general abstraction, one that tells you to check before touching anything that could potentially be hot. Organizations over a certain size often remove us from the direct consequences of our decisions. When we make decisions that other people carry out, we are one or more levels removed and may not immediately be able to update our understanding.

*PART 17: Deep Work and
Leadership and Accountability*

Step 121-Slow Down

- 1. Do Not Rush Any Tasks I will do At Any Time.**
- 2. Listen and Apply Book “The Slow Fix Solve Problems, Work Smarter, and Live Better in a World Addicted to Speed”**
- 3. Listen and Apply Book *In Praise Of Slowness Challenging the Cult of Speed BY Carl Honore.**

- I. We live in a world scarce of understanding and abundant with information. We complain that we never have any free time yet we seek distraction. If work can't distract us, we distract ourselves. We crave perpetual stimulation and motion. We're so busy that our free time comes in 20 second bursts, just long enough for us to read the gist and assume we understand. If we are to synthesize learning and understanding we need time to think.
- II. The modern storm of bits and stimulation, relents only when we sleep. (And then only if we remember to turn off the phone.) Lost in all of this is the art of stillness. We live in a world with more information than ever and yet we understand less. We have come into the belief that the simple act of reading confers understanding. Worse, most of our reading is elementary reading, or skimming — a far cry from syntopical reading, which seems more fertile for the mind willing to do the work.
- III. But that's just it. We don't want, or can't find the time, to do the work that's required to hold an opinion. It's much easier to simply read the opinions of another and let them think for us.
- IV. Understanding comes from focusing, chewing, and relentlessly ragging on a problem. It comes with false starts, dead ends, and frustration. Thinking requires time and space. It's slow. It means saying I don't know. In short, thinking is everything the modern workplace is designed to eradicate.
- V. We're expected to have an opinion about everything and yet our time to think is near zero. We hold more opinions than ever but have less understanding. We don't even understand ourselves. How could it be otherwise?
- VI. As Milan Kundera wrote in his 1996 novella Slowness, “When things happen too fast, nobody can be certain about anything, about anything at all, not even about himself. “In our fast-moving modern world, it always seems that the time-train is

pulling out of the station just as we reach the platform. No matter how fast we go, no matter how cleverly we schedule, there are never enough hours in the day.”

VII. Carl Honore, wrote a book, In Praise of Slowness: Challenging the Cult of Speed, to explore why we’re always in such a rush, what if anything is the cure for time-sickness, and whether it’s desirable to slow down. The book is not an all-out declaration of war against speed. Speed has helped to remake our world in ways that are wonderful and liberating. Who wants to live without the Internet or jet travel? The problem is that our love of speed, our obsession with doing more and more in less and less time, has gone too far; it has turned into an addiction, a kind of idolatry. Even when speed starts to backfire, we invoke the go-faster gospel.

VIII. When we rush, we skim the surface, and fail to make real connections with the world or other people.” Moreover we don’t make connections with ideas. We don’t synthesize. We don’t test theories over time. We don’t play with ideas.

IX. The implications on thinking are fascinating. We are all fast-thinkers now. We have forgotten how to look forward to things, and how to enjoy the moment when they arrive. Restaurants report that hurried diners increasingly pay the bill and order a taxi while eating dessert. Many fans leave sporting events early, no matter how close the score is, simply to steal a march on the traffic. Then there is the curse of multi-tasking. Doing two things at once seems so clever, so efficient, so modern. And yet what it often means is doing two things not very well. Like many people, I read the paper while watching TV— and find that I get less out of both. In this media-drenched, data-rich, channel-surfing, computer-gaming age, we have lost the art of doing nothing, of shutting out the background noise and distractions, of slowing down and simply being alone with our thoughts. Boredom — the word itself hardly existed 150 years ago— is a modern invention. Remove all stimulation, and we fidget, panic and look for something, anything, to do to make use of the time. When did you last see someone just gazing out the window on a train? Everyone is too busy reading the paper, playing video games, listening to iPods, working on the laptop, yammering into mobile phones. Instead of thinking deeply, or letting an idea simmer in the back of the mind, our instinct now is to reach for the nearest sound bite. In modern warfare, correspondents in the field and pundits in the studio spew out instant analyses of events as they occur. Often their insights turn out to be wrong. But that hardly matters nowadays: in the land of speed, the man with the instant response is king. With satellite feeds and twenty-four-hour news channels, the electronic media is dominated by what one

French sociologist dubbed “le fast thinker”— a person who can, without skipping a beat, summon up a glib answer to any question.

- X. Fast eats time. One consequence of fast is that we make poor decision after poor decision. Those decisions don’t go away never to be seen again. It’s not like we make a bad decision and we’re done with it. No, the consequences are much worse. Poor decisions eat time. They come back to haunt you. They create issue after issue. They feed into the perpetual motion machine of busyness. And in a culture where people wear busyness as a badge of honor bad decisions actually lead us to think that we’re doing more.

4. Do The Tasks Slowly, and Step By Step.

5. The Art of Slowing down and Do Not Rush Anything.

- I. The Art of Stillness is a persuasively argued case for the pleasures of slowing down and being in one place. Today we’re going faster and faster in search of contentment and meaning. This is largely a recipe for ensuring we will never be happy. We have the sense, too often, of running at top speed and never being able to catch up.
- II. Too many of us see going nowhere as turning away from something rather than turning towards something.
- III. Going nowhere isn’t about turning your back on the world; it’s about stepping away now and then so that you can see the world more clearly and love it more deeply. “There is nothing either good or bad, but thinking makes it so.”
- IV. The idea behind choosing to sit still long enough to learn about yourself is simple and has been around for ages. Marcus Aurelius and Epictetus reminded us many millennia ago that it’s how we respond to our experiences, not the experiences themselves, which shape us.
- V. The greatest weapon against stress is our ability to choose one thought over another. Part of making better decisions is making time to think. Something that few of us are able to do.
- VI. “Our creations come not when we’re out in the world, gathering impressions, but when we’re sitting still, turning those impressions into sentences.

Step 122 - NOT MULTITASK.

1. Of course you can do more than one thing at once. The catch is you can't do more than one thing at once that requires concentration. You can walk and chew gum, but you can't write an email and a report at the same time. When you're doing two things at once that are cognitively demanding, what you're really doing is switching back and forth very quickly from one task to another.
2. There is a mental cost—called a switching cost—to all of this multitasking. But that's not all it makes deep thinking impossible.
3. I think people that multitask pay a huge price. They think they're being extra productive, and I think they're (out of their mind). I use the metaphor of the one-legged man in the ass-kicking contest. I think when you multi-task so much, you don't have time to think about anything deeply. You're giving the world an advantage you shouldn't do. Practically everybody is drifting into that mistake. Concentrating hard on something that is important is. I can't succeed at all without doing it. I did not succeed in life by intelligence. I succeeded because I have a long attention span.
4. It sounds counter-intuitive but if you want to increase discretionary time and reduce stress you need to schedule time to think. The tiny fragments of time many of us find ourselves with have a negative effect on our ability to think deeply about a problem. Furthermore they impede our ability to learn — we stay at a surface level and never move into a deep understanding. Deresiewicz warns: "You simply cannot (think) in bursts of 20 seconds at a time, constantly interrupted by Facebook messages or Twitter tweets, or fiddling with your iPod, or watching something on YouTube."
5. The opposite approach is to focus on a problem or subject and try to achieve a deep fluency. How many of us, however, have time? We don't do the work required to have an opinion. Instead we operate with surface knowledge. We tackle problems with the first thought that comes to mind. Because we make a poor initial decision, we spend countless hours attempting to correct it. No wonder we have no time to think. We're not heeding the advice of Joseph Tussman and letting the world do the work for us.
6. Listen and Apply The Following Books:

A. The Multitasking Mind By Dario Saliveci

Step 123-You Have Required To Do The Work For Leadership.

1. When Give Opinion on Anything, Do Not Be so Angry and Mean to Others.
2. People Need To Stop Doing By Coming Unprepared To Give Opinion On Any Subject, Without Having Good Idea Of The Literature, and Arguments Written on Topic and Theme Available To Them. The people coming unprepared and not doing any Hard Work To Have an Opinion On The Subject or Topic. When People Coming Overconfidence, which could be resulting in Lack of Preparation, Which Could Lead That Your Position can be Destroyed with Ease. They simply won't do the work required. It's easy to come home, sit on the couch, watch TV, and zone out until bedtime rolls around. But that's not going to help you get smarter.
 - A. People Who Do Not Put The Required Work: The first thing they always do is tell you what they think. When someone has an opinion about everything, they want to share it with you. They often tout stats and research as if they had an imaginary checklist of facts they need to be able to rattle off to establish themselves as an expert in a field they actually know very little about. Because they have an opinion on everything, they are quick to judge others – for their lack of opinions, for their lack of knowledge, for their lack of outrage, and the list goes on.
 - B. People who have opinions about everything barf so much noise that it's hard to find the signal. Your brain has to work overtime to figure out if they did the work to come up with their opinions themselves or if they're simply regurgitating some oped in a newspaper. Over time, opinionated people also end up in their own prisons and they try to take you with them.
 - C. The problem comes from how we see the world. Our opinions are often rooted in how we think the world should work, according to our morals, values, and principles. If we see the world through the lens of our opinions, much of what happens will not agree with us. This is feedback, and how we respond to this feedback is key.

3. How to Get Smarter Read. A lot. Warren Buffett says, "I just sit in my office and read all day." What does that mean? He estimates that he spends 80% of his working day reading and thinking. When asked how to get smarter, Buffett once held up stacks of paper and said, "Read 500 pages like this every week. That's how knowledge builds up, like compound interest." All of us can build our knowledge, but most of us won't put in the effort. "Go to bed smarter than when you woke up."
4. How Long Does it Take To Prepare:
 - A. Depend on the topic and opponent, and how much he's written.
 - B. If the opponent nothing published, then there was very little preparation to be made because I simply didn't know what to expect.
 - C. On the other hand, if the opponent has published lots of written work and have some videos. Read and what his written and videos and prepare the summaries articles, videos, and have sense where he is coming from. This can take Weeks or Months.

5. Before Preparation. The difference between the people who do the work and the people who just reel off memorized opinions is huge. When you do the work, you can answer the next question. You know when to follow the rules and when they'll get you in trouble. When I did my postgraduate I was surrounded by people who could answer the test questions. They got good grades — actually, they got *great* grades but an odd thing happened after school: a lot of those people couldn't apply their knowledge to problems they hadn't seen before. They were chauffeurs — they knew the memorized answer. They couldn't answer the next question. We're all chauffeurs in some aspects of our lives. This is why understanding your circle of competence is so critical to living a rational life.

I. Circle of Competence:

A. **Circle Of Competence**-Understanding my Circle of Competence helps to avoid problems, identify opportunities for improvement and learn from Others. Circle of Competence is simple: Each of us, through experience or study, has built up useful knowledge on certain areas of the world. Some areas are understood by most of us, while some areas require a lot more specialty to evaluate. For example, most of us have a basic understanding of the economics of a restaurant: You rent or buy space, spend money to outfit the place and then hire employees to seat, serve, cook, and clean. (And, if you don't want to do it yourself, manage.) From there, it's a matter of generating enough traffic and setting the appropriate prices to generate a profit on the food and drinks you serve—after all of your operating expenses have been paid. Though the cuisine, atmosphere, and price points will vary by restaurant, they all have to follow the same economic formula. That basic knowledge, along with some understanding of accounting and a little bit of study, would enable one to evaluate and invest in any number of restaurants and restaurant chains, public or private. It's not all that complicated. Far more important is to honestly define what we do know and stick to those areas. Our circle of competence can be widened, but only slowly and over time. Mistakes are most often made when straying from this discipline. Where should we devote our limited time in life, to achieve the most success? So, the simple takeaway here is clear. If you want to improve your odds of success in life and business, then define the perimeter of your circle of competence, and operate inside. Over time, work to expand that circle

but never fool yourself about where it stands today, and never be afraid to say “I don’t know.”

II. Two Type of Knowledge: The Max Planck and Chauffeur Test

A. The Two Types of Knowledge: The Max Planck and Chauffeur Test: How to distinguish between the two types of knowledge: real knowledge and pretend knowledge.

- The first type of knowledge is real. It can’t be bought. It can’t be copied. If you want real knowledge you need to earn it. One is Planck knowledge, the people who really know. They’ve paid the dues, they have the aptitude. You are going to have the problem in your life of getting the responsibility into the people with the Planck knowledge and away from the people with the chauffeur knowledge. Real knowledge comes when people do the work. The problem is that it’s difficult to separate the two. This is the Batesian Mimicry problem. One way to tease out the difference between Planck and chauffeur knowledge is to ask them why.
- The second type of knowledge is copied. On the surface you know the answer but you lack the understanding to show your work. Then we’ve got chauffeur knowledge. They’ve learned the talk. They may have a big head of hair, they may have fine temper in the voice, they’ll make a hell of an impression. But in the end, all they have is chauffeur knowledge. I think I’ve just described practically every politician in the United States. We have the people who don’t do the work — they pretend. While they’ve learned to put on a good show, they lack understanding. They can’t answer questions that don’t rely on memorization. They can’t explain things without using jargon or vague terms. They have no idea how things interact. They can’t predict the consequences. The problem is that it’s difficult to separate the two. This is the Batesian Mimicry problem. One way to tease out the difference between Planck and chauffeur knowledge is to ask them why.
- How To Distinguish Real Knowledge and Fake Knowledge. With journalists, it is more difficult. Some have acquired true knowledge.

Often they are veteran reporters who have specialized for years in a clearly defined area. They make a serious effort to understand the complexity of a subject and to communicate it. They tend to write long articles that highlight a variety of cases and exceptions. The majority of journalists, however, fall into the category of chauffeur. They conjure up articles off the tops of their heads or, rather, from Google searches. Their texts are one-sided, short, and— often as compensation for their patchy knowledge. The same superficiality is present in business. The larger a company, the more the CEO is expected to possess “star quality.” Dedication, solemnity, and reliability are undervalued, at least at the top. Too often shareholders and business journalists seem to believe that showmanship will deliver better results, which is obviously not the case. One way to guard against this is to understand your circle of competence. Dobelli concludes with some advice worth taking to heart. Be on the lookout for chauffeur knowledge. Do not confuse the company spokesperson, the ringmaster, the newscaster, the schmoozer, the verbiage vendor, or the cliché generator with those who possess true knowledge. How do you recognize the difference? There is a clear indicator: True experts recognize the limits of what they know and what they do not know. If they find themselves outside their circle of competence, they keep quiet or simply say, “I don’t know.” This they utter unapologetically, even with a certain pride. From chauffeurs, we hear every line except this.

III. Batesian Mimicry Problem. Batesian Mimicry: Why Copycats Are Successful.

Mimic and the Real Thing:

- A. "There's two kinds of snakes you come across. There's the Texas Coral Snake, and the Mexican Milk Snake, and they both look exactly alike. The Texas Coral Snake is dangerous, it's venomous, it can kill you in a minute. The Mexican Milk Snake can't do anything to you; it's an impostor." How is it that these two look alike? It's due to a phenomenon called Batesian Mimicry.
- B. In the 1850s, the naturalist Henry Walter Bates found a certain set of butterflies who were clearly *not* of the same species but whose wings looked almost the same to the naked eye. After thinking it over, Bates eventually figured out what was going on: While the butterflies which were toxic to potential predators (the "models") were able to operate freely and relatively unmolested, there had also developed a "mimic" population of butterflies which wasn't toxic at all, yet still went untouched! In fact, biologists eventually figured out that the more toxic and dangerous the "model" was and the more frequently they appeared in the local population, the easier it was for its "mimics" to get by! Predators simply wouldn't take the risk of mixing up the two. If there aren't as many "models" around or they aren't that dangerous, the mimics have a harder time.
- C. This is a wonderful model, and in the practical world we live in, a similar phenomenon abounds: Copycats or "pretenders to the throne" are often very effective, very convincing "mimics" of the true champions. They dress the part, they talk the talk, and they know what buttons to push. But in the end, they are merely chauffeurs. We see a very Batesian effect at work: The more impressive the "model," the more effective its mimics can be in convincing people they too are impressive, and in all the same ways. But for every Warren Buffett (just one by our count), there has been many "future" Warren Buffett's. For every Steve Jobs, there have been many "next" Steve Jobs'. In fact, sometimes even just *appearances* can be quite convincing: now-disgraced Theranos founder Elizabeth Holmes was very fond of wearing a very Steve Jobsian black turtleneck outfit. Because they can be very convincing, we must be wise enough to watch out for Batesian mimicry

— even in ourselves. This brings up an interesting, at times paradoxical, question: Who can best tell the difference between a Coral Snake and its Mimics? The Coral Snake itself. The real thing knows a fake. It's worth taking the time to work on learning all the big ideas you can find, not just the ones you want to learn. In that search, you'll find a host of big winners you didn't even know existed.

6. Preparation:

- A. While we all hold an opinion on almost everything. Have I do the work required to have an opinion on any Subject? Never allow myself to have an opinion on anything that I don't know the other side's argument better than they do. The work required to have an opinion is very hard part, have I avoid it?
 - I. I have to do the reading.
 - II. I have to talk to competent people and understand their arguments.
 - III. Never try to be biased toward any of the side, but question both side of the argument.
 - IV. Do not support any side, until all the facts are put out there, clear and obvious.
 - V. Once known all the facts then analyse both sides of the argument like William Lane Craig.
 - VI. I have to think about the key variables and how they interact over time.
 - VII. I have to listen and chase down arguments that run counter to your views.
 - VIII. I have to think about how you might be fooling yourself.
 - IX. I have to see the issue from multiple perspectives.
 - X. I have to think.
 - XI. I need to become your most intelligent critic and have the intellectual honesty to kill some of your best-loved ideas.
 - XII. Be honest with yourself and open minded. ANALYSE both side of the argument logically and see which is true logically. Means has the clear terms, premises are true, and conclusion follows from premises.
 - XIII. Never say your opinion about anything that requires the analysis of the arguments and facts. Work very bery hard to have an opinion about anything.
 - XIV. Listen very carefully other side and use ancient method *state the opposition argument in my own words and ask him/her if the argument I

stated in my own words represents correctly their argument and if I UNDERSTOOD Correctly their arguments.

XV. Never use cheap shots to win argument, like logical fallacies.

XVI. Debate and discussion is not about just win at any cost, but let other person to think about your arguments and engage with them. Second reason never use in discussion cheap shots toward other person, but be civil. Third reason is win the debate and discussion. Fourth is find the truth.

B. For Affirmative and Negative Case:

- I. Read, analyse, Research, Syntopicon and Investigate Published Work.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of My own Arguments
- II. Read Opponents Books, Articles, Newspapers, Blogs. Reading Published work. What objections he would raise against the topic and prepare the responses for each of these points.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of opponent Arguments.
- III. Watch Video. Watching Videos of the opponent. What objections he would raise against the topic and prepare the responses for each of these points.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of My own Arguments.
- IV. Listen The recording that the opposition made, in which he addresses these issues.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of My own Arguments.
- V. Talk with People who are students in his class, who can tell me, privately, insights into his thinking and character.
- VI. If that sounds like a lot of work, just say, “I don’t have an opinion on that; why don’t you tell me how you got to have such a firm one? It sounds like I could learn something.”
- VII. Another way to get smarter, outside of reading, is to surround yourself with people who are not afraid to challenge your ideas. “Develop into a lifelong self-learner through voracious reading; cultivate curiosity and strive to become a little wiser every day.”

7. Compound Knowledge- Are The Resources I will Choose Concentrating On the Expiring Information or Compound Knowledge?

- I. Are on the Resources providing expiring information?
 - A. Will you care about what you're reading in a month? In a year? In five years?
 - B. Are you focused enough on the same thing to build cumulative knowledge or are you too spread out?
 - C. What do you spend time on that's likely to change in the next few years? What's not likely to change?
 - D. What would need to happen for you to stop outsourcing organisation of information to the computer?
- II. Signs of The Information in the resources are expiring
 - A. First, it's marketed to you.
 - B. Second, lacking details and nuance, it's easily digestible. This is why it's commonly telling you what happened, not why it happened or under what conditions it might happen again
 - C. Third, it won't be relevant in a month or a year. Expiring information is one reason I stopped reading most news. It's a false map.
- III. While most of us focus on consuming information that we won't care about next month, let alone next year, focus on knowledge and companies that change very, very slowly or not at all. And because the information he was learning changed slowly he could compound his knowledge over time.
- IV. Doing his own thinking and vacuums up the details. When we don't think for ourselves it's easy to put the blame on someone else, to "pass the buck" so to speak.
- V. When we consume information that doesn't expire or expires slowly; is very detailed; and we spend time thinking about it not passing the buck, we can match patterns. This is how you learn to see what other people are missing. The longer you do this, the more advantage you get.
- VI. Just like the rest of us, Buffett's dependent on information and knowledge to make great decisions. Unlike most of us, he has a great memory—perhaps because he's not trying to outsource his memory or thinking to others.
- VII. A lot of what the snowball is about the concept of learning, and creating, and the advantage of having the information and knowing it. When I came here today one

of the things that I was thinking is that what you do is so much at the intersection, because retrieving information is different from having it already in your head.

VIII. What you do is different. You work on manipulating how you use the information.

In fact, Warren Buffett and Charlie Munger have the files in their head. That's why they aren't really out there googling all the time looking for, trying to look stuff up, because they already know it.

IX. I think a lot of the work that you do here is helpful to the ordinary person, but Warren Buffett or Charlie Munger don't need it. At the same time, the lesson that they have, which is that learning yourself, making yourself as smart as you can is extremely valid, and not just relying on a library where you can look something up all the time, because a lot of times when you need to make a decision, and you need 50 pieces of information, you need to know it then.

8. The Art of Anticipation of Objections.

- A. Analyse My Arguments, and Scrutinise The arguments by using Rules of Reading.
- B. Analyse the arguments of the opponent. Scrutinise Their arguments by using Rules of Reading.
- C. Analyse My own arguments. Scrutinise My own arguments, and the potential Loopholes in the argument by Use Rules of Reading.
- D. Use Think, Logic, Strategem, Thinking models.
- E. Write.
- F. Prepare The responses to anticipated objections that, I think the opponent will bring up.
- G. Be intellectually Prepared. This means That I need to know my arguments, so well, that nothing new can surprise me. I would also invest lots of time in knowing and know better opposite side arguments. I would read both side of the arguments, and work Hard on analysing the arguments and evidence of both sides. Doing the work required to hold an opinion means you can argue against yourself better than others can. Only then can you say, "I can hold this view because I can't find anyone else who can argue better against my view." Great thinkers, like Charles Darwin, did the work. And it's one of the biggest reasons he's buried at Westminster Abbey. While we all hold an opinion on almost everything. Have I do the work required to have an opinion on any Subject? Never allow myself to have an opinion on anything that I don't know the other side's argument better than they do. The work required to have an opinion is very hard part, have I avoid it? If that sounds like a lot of work, just say, "I don't have an opinion on that; why don't you tell me how you got to have such a firm one? It sounds like I could learn something."
- H. Doing the work required to hold an opinion means you can argue against yourself better than others can. Only then can you say, "I can hold this view because I can't find anyone else who can argue better against my view." Great thinkers, like Charles Darwin, did the work. And it's one of the biggest reasons he's buried at Westminster Abbey.
- I. Doing the work counteracts our natural desire to seek out only information that confirms what we believe we know. When Darwin encountered opinions or facts that ran contrary to his ideas, he endeavored not only to listen but also not to rest

until he could either argue better than his challengers or understand how the fact fit. Darwin did the work. It's wasn't easy, but that's the point.

- J. Have the best work ethic on daily basis. This is everyday process, and try to figure it out, the strengths and weaknesses of my position and opposing person position, This leads to the True Confidence.
- K. As Per Kobe Bryant statement: Trivial things should not be taken your attention. The attentions should be focused on things that is very important. Anything outside of the most important things in life, you should not have time for. You Should love the challenge in life, and always be curious, if you can be at the top , as these greats in that area. Always focus on one thing and not multiple things, this gives an edge and advantage over other people, who focusing on multiple things in life. The World Becomes a library to you, to be better at your craft.: Everything you see whether TV show I saw, Books, Journals, I read, whether discussion, debate I listen, people I talk to. Everything was done to try to learn to become better at the craft your focusing. When you have this point of view, then the world becomes your library to help you to become better at the craft.
- L. I Always need to ask myself: Have I done the work required to have an opinion on any Subject? Never allow myself to have an opinion on anything that I don't know the other side's argument better than they do. The work required to have an opinion is very hard part, have I avoid it? If that sounds like a lot of work, just say, "I don't have an opinion on that; why don't you tell me how you got to have such a firm one? It sounds like I could learn something."
- M. I might need to Suspend my judgement and tell them that I do not have an opinion on this specific Topic.
- N. Never Under Prepare, but Vastly Over Prepare for the Opponent and their arguments and responses
- O. Spend years in preparation, take debate class at the college or university. You need to participate in debates. You need to have mock debates, where someone play role of your opponent, and then you respond to them. You need to do reading and learn how to flow the debates. How to construct affirmative case and negative case. You need to take time to prepare and have enormous preparation.
- P. Memorize the arguments for my case

9. When Dialogue, Discussion, Debate Takes A Place.

A. As Affirmative Speaker, you need to present Prima Facie Case for proposition that is under debate. Prima Facie Case will be one that will establish the truth of proposition you are defending. If I am defending proposition that God Exist, I will want to give 3-5 arguments leading to that Conclusion, that God Exists, and then I will lay those out with great clarity in my opening speech, and say this is the groundwork for the debate. I am not interested in talking about other issues for example if Christianity bad for society Then, I come back to those in every speech over and over again. The goal is to make opponent argue on your grounds. You do not go over to his grounds, and let your audience forget, your affirmative case, rather you reorganise opponent speech, so that you answer his objections in so far as they reply to your arguments, so you may answer them in a very different order than he gave them, because you will be seeing for example: now what answer or response did he have to the cosmological argument, I see two basic responses and then you deal with them.

- Make Briefs, where I have suitable objection, and then have two or three responses to those objections.
- Use The Brief During Exchange with the Opponent. File these Briefs into Folders, and spread These Manila Folders out in front of me on Desk, When I am interacting with the Opponent. Once the opponent Rises his point I just pull These briefs from these folders and never have to think on my feet because I am completely prepared. Key is never have to think on the feet to be so well prepared, that I would have my responses ready for anything he brings up.
- Quote Peer Review Scientific Articles on the topic in support the conclusions.

B. Take Notes While the Opposition is speaking:

- How To Take Notes- Flow Chart. By Taking Notes, I am sure that I am responding to my opponent's arguments and everything he brings up.

- I. Make 11-12 Columns on the Pad. Prepare the left column in advance of the communication, debate. The Left Column needs to be filled in, if you starting first. If not, then leave left column as blank.
- II. First Left Hand Column Are My Arguments.
- III. Second Left Hand Column are Opposition Arguments and Responses to My arguments.
- IV. Third Left Column are My Responses to the Opponent responses.
- V. Fourth Left Hand Column are My Rebuttal.
- VI. Fifth Left Hand Column are Opponent Rebuttal.
- VII. Sixth Left Hand Column are my Responses to the Opponent rebuttal.
- VIII. Seventh Left Hand Column is the Final My Rebuttal.
- IX. Eight Left Hand Column is The opponent Rebuttal.
- X. Ninth Left Hand Column is my closing statements.
- XI. Tenth Left Hand Column is the opponent closing statements.
- XII. Eleventh Left Hand Column is the Cross Examination.
 - My Answer.
 - Opponent Answer.
 - My response to the response of the opponent.

C. Always Remind the audience what are your three to five arguments and what are the responses of the opponent, if any to your arguments.

D. Always allow the opponent allow to lay out his argument without interruption.

E. Take the opponent arguments and put in my own words and correctly represent their argument carefully without misrepresentation.

F. Be Honest.

G. Be Open Minded.

H. Always from Your side be honest and rigorous exchange of arguments and counter Arguments from which me and opponent would benefit.

I. One of good technique is whenever you can quote an opponent against himself, this is powerful device. Have the manuscript, point to the footnote, cite the book, and the quotation and have the page number.

J. Never Take Cheap Shots at the Opponent.

- K. Encourage not just trust someone say so, but demand published peer reviewed articles in support of the positions that one take
- L. Always look at the reality of the situation, and do not let the emotion cloud the situation and the execution. Always be in the present and the moment.

Step 124-Use Rules of Reading for Leadership And Accountability

1. Listen, Follow and Apply Rules of Reading of Bible Study, Deep Work, Deep Study, Analysis, Syntopicon and Research For Leadership And Accountability.
 - A. **VERY VERY FAST Reading- Skimming. Pages 47-51.**
 - B. **VERY FAST READING- Entertainment.**
 - I. **Method 1-Speed Reading. FAST Reading. Pages 59-64.**
 - C. **FAST READING: Methods for Basic Knowledge For Deep Work or Bible Study.**
 - I. **Method 1-Survey, Question, Read, Recite, Record, Reflect (SQR4). Pages 66-67.**
 - II. **Method 2-Use 80/20 Principle For Reading. Pages 68.**
 - III. **Method 3-Preview, Question, Read, Summary,Test (PQRST). Page 69.**
 - IV. **Method 4-Flip Through Pages and Analyse. Page 70.**
 - V. **Method 5-Devotional Bible Study by Using Devotional Books. Pages 71-72.**
 - VI. **Method 6-Devotional Bible Read. Pages 73-74.**

D. Deep Work, Deep Study, Bible Study or Any Book- SLOW Reading- Complex Text.

- I. Method 1-Chapter Summary Method. Pages 143-147.**
- II. Method 2-Character Quality Method. Pages 148-160.**
- III. Method 3-Thematic Method. Pages 161-163.**
- IV. Method 4-Biographical Method. Pages 164-176.**
- V. Method 5-Topical Method. Pages 177-180.**
- VI. Method 6-Word Study Method. Pages 181-189.**
- VII. Method 7-Book Background Method. Pages 190-194.**
- VIII. Method 8-Book Survey Method. Pages 195-205.**
- IX. Method 9-Chapter Analysis Method. Pages 206-215.**
- X. Method 10-Paragraph Study. Pages 216-229.**
- XI. Method 11-Verse by Verse Analysis Method. Pages 230-234.**
- XII. Method 12-Book Synthesis Method. Pages 235-238.**
- XIII. Method 13-Theological Study Method of Bible Study. Pages 239-245.**
- XIV. Method 14-Studying Bible Prophecy. Pages 246-259.**
- XV. Method 15-Typological Study Method. Pages 260-262.**
- XVI. Method 16- John MacArthur Way Bible Study. Pages 263-268.**
- XVII. Method 17-Inductive Bible Study Method. Pages 269-296.**
- XVIII. Method 18-BIBLICAL HERMENEUTICS. Pages 297-302.**
- XIX. Method 19-Theological Group of Principles. Pages 303-306.**
- XX. Method 20- How To Read A Book Pages 307.**

E. VERY VERY SLOW READING- COMPLEX TEXT. Deep Work, Shallow Work, Bible Study, Analysis of Text, Research, Investigative Journalism, Investigation and Syntopicon, Mixed Method.

- I. Method 21- How To Read A Book By Mortimer Adler Various edition Pages 341.**
- II. Method 22-How To Read A Book For Various Books. Pages 342-600.**
- III. Method 23- Syntopicon Pages 601-642.**
- IV. Method 24-The Craft of Research. Pages 644-882.**
- V. Method 25-Research Books can Be Used. Pages 883-897.**
- VI. Method 26-Investigative Journalism. Pages 898-923.**
- VII. Method 27-Mixed Methods of Rules of Reading. Pages 924-942.**

2. Apply The Books To Leadership.

Step 125-Leadership and Accountability

Books

1. **Listen, Follow And Apply Rules of Reading Part 1 to 15, before looking into Leadership and Accountability.**
2. **Listen, Follow and Apply the following Books.**
 - A. **How To Read A Book By Mortimer Adler**
 - B. **Socratic Logic, Method and Questioning.**
 - C. **Start with Why_ How Great Leaders Inspire Everyone to Take Action.**
 - D. **The Dichotomy of Leadership_ Balancing the Challenges of Extreme Ownership to Lead and Win.**
 - E. **The seven habits of highly effective people _ restoring the character ethic.**
 - F. **The-Art-of-Leadership.**
 - G. **Tools of Titans_ The Tactics, Routines, and Habits of Billionaires, Icons, and World-Class Performers.**
 - H. **Why Great Leaders Don't Take Yes for an Answer Managing.**
 - I. **Best Practices in Leadership Development and Organization Change_ How the Best Companies Ensure Meaningful Change and Sustainable.**
 - J. **Coaching for Leadership_ The Practice of Leadership Coaching from the World's Greatest Coaches.**
 - K. **Develop Your Leadership Skills_ Develop Yourself as a Leader - Lead at a Strategic Level - Grow Leaders in Your Organisation.**
 - L. **Educational Leadership_ Personal Growth for Professional Development.**
 - M. **Focus on Leadership_ Servant-Leadership for the 21st Century.**
 - N. **Good Leaders Ask Great Questions_ Your Foundation for Successful Leadership.**
 - O. **Strategic Leadership**
 - P. **The Leadership Challenge_ Activities Book (J-B Leadership Challenge.**
 - Q. **The Maxwell Leadership Bible.**
 - R. **The Only Leadership Book You'll Ever Need_ How to Build Organizations Where Employees Love to Come to Work.**
 - S. **The Bible on Leadership.**

- 3. Listen, Follow and Apply the following Books.**
- A. How To Read A Book By Mortimer Adler**
 - B. Socratic Logic, Method and Questioning.**
 - C. 12 Accountability Commitments.**
 - D. OZ Principle: Getting Results Through Individual and Organizational Accountability.**
 - E. Accountability in the WorkPlace.**
 - F. The Dichotomy of Leadership_ Balancing the Challenges of Extreme Ownership to Lead and Win.**
 - G. Summary of QBQ The Question Behind Question**
 - H. NDSU QBQ.**

Step 126-Thinking, Logic and Mental Model

1. Listen, Follow and Apply Thinking, Logic and Mental Model PART 7

Part 7: Thinking, Logic and Mental Model For Deep Work or Deep Study, Or Bible Study

- 1. Step 57- Slow Down. Pages 1061-1063.**
- 2. Step 58- NOT MULTITASK. Pages 1064.**
- 3. Step 59-You Have Required To Do The Work For Thinking and Applying Mental Tool Models. Pages 1065-1080.**
- 4. Step 60-Why Critical Thinking, Logic, Thinking and Mental Tools Are Important? Pages 1081-1083.**
- 5. Step 61-Intradisciplinary Thinking. Pages 1084-1125.**
- 6. Step 62-Multidisciplinary Thinking. Pages 1126-1168.**
- 7. Step 63-CrossDisciplinary Thinking. Pages 1169-1211.**
- 8. Step 64-Interdisciplinary Thinking. Pages 1212-1254.**
- 9. Step 65-Transdisciplinary Thinking. Pages 1255-1298.**
- 10. Step 66-Journaling. Pages 1299.**
- 11. Step 67-Letting The World Do The Work For You. Pages 1300-1305.**
- 12. Step 68-Journaling. Pages 1306.**
- 13. Step 69-Letting The World Do The Work For You. Pages 1307-1312.**

Step 127-Leaders and Followers, Planners and Doers

The author Marshall Goldsmith has a gift for taking classic theories and adding to them, or slightly modifying them, to construct something new and interesting.

A good example of this is what he does with Situational Leadership in the book Triggers: Creating Behavior That Lasts – Becoming the Person You Want to Be.

He takes the original ideas postulated by Paul Hersey and Ken Blanchard in their theory of Situational Leadership and adds an interesting spin, allowing us to use some of the insights more personally.

Situational leadership is the idea that one needs to constantly adapt their leadership style to the ever changing environment in which they operate.

If a specific style works in one situation with one particular individual, that doesn't mean we should adopt that style for all people and situations. However, in part because success is reinforced, that is generally what we do.

Hersey and Blanchard's premise is that leaders need to adapt their style to fit the performance readiness of their followers. Readiness not only varies by person, it also varies by task. Followers have different levels of motivation and ability for different tasks.

Leaders need to acknowledge that situations change along with the readiness of their staff. To be most effective, different people require different types of leadership.

Hersey and Blanchard outlined four distinct styles:

1. *Directing is for employees requiring a lot of specific guidance to complete the task. The leader might say, 'Chris, here's what I'd like you to do, step by step. And here's when I need it done.' It's primarily a one-way conversation, with little input from the employee.*
2. *Coaching is for employees who need more than average guidance to complete the task, but with above-average amounts of two-way dialogue. Coaching is for people who both want and need to learn. The leader might say, 'Chris, here's what I'd like you to do,' and then ask for input: 'What do you think, Chris?'*
3. *Supporting is for employees with the skills to complete the task but who may lack the confidence to do it on their own. This style features below-average amounts of*

direction. The leader might say, 'Chris, here's the task, How do you think it should be done? Let's talk about it. How can I help you on this one?'

4. *Delegating is for employees who score high on motivation, ability, and confidence. They know what to do, how to do it, and can do it on their own. The leader might say, 'Chris, here's the assignment. You have a great track record. If I can help, just ask. If not, you're on your own.'*

The four styles are quite different. The idea is to try and measure the need of your employee and choose the style that best fits them at that particular moment in time. The measuring process needs to happen continually for you to be most effective. The style which best helps Chris in situation X might not be the one that will help him in situation Y.

Now for the twist.

Hersey and Blanchard's situational leadership is a perfect analogue to a hidden dynamic that exists within us when we attempt to change our behavior. It's the same dynamic whether you call it leader and follower, planner and doer, or manager and employee. The terms are interchangeable as far as I'm concerned.

As we go through life making plans to be a better friend, partner, worker, athlete, parent, son, or daughter, inside each of us are two separate personas. There's the leader/planner/manager who plans to change his or her ways. And there's the follower/doer/employee who must execute the plan.

Goldsmith argues that whether you are trying to lead other people or lead yourself, the obstacles are very much the same. You still have to deal with all the variables in the environment: temptations pushing you away from your objective, motivation issues, and self-discipline issues. One result is that we tend to be superior planners but inferior doers. We talk a good game.

If you take a moment to think of a recent plan that you devised but never executed, you'll realize that Goldsmith is onto something here. Would a successful leader come up with a beautiful plan, throw it out to their employees, and then walk away and hope for the best? No.

To improve the odds of success, a leader would check in. They would look for obstacles to remove. They would want feedback on progression. They would be an active part of implementing the plan. We know this, yet we don't do it in our own work and lives. We don't manage execution.

What if the planner in each of us, like an effective leader with his or her subordinates, could size up the situation at any point during the day and adopt the appropriate management style for the doer in us? It's a simple two-step: measure the need, choose the style.

It gives you such a new perspective to think of your goals in this way. It allows you to step back from the situation and clearly see where you are getting off course. Just step into execution mode and out of planning mode, as any good hands-on leader would do.

We don't adequately weigh many of your past experiences/failures. This may be a willful denial of why you have failed at a task in the past or it could simply be that you've never taken the time for reflection.

It's not just environmental intrusions and unpredicted events that upset our plans. It's also our willful discounting of past experience. We make plans that are wholly contradicted by our previous actions.

The planner in us is convinced this time it will be different. Yet if you don't understand why you failed, you're doomed to repeat folly. Learning from our mistakes is key to increasing the odds to achieve our personal and professional goals.

Goldsmith's book is filled with insightful ideas. His decades of experience in coaching leaders is evident throughout the pages; both in the way he highlights his ideas with meaningful examples and the way he explains the evolution in his own thinking. You will find yourself identifying with his client's issues and walking through the solutions, endowing you with practical tools to help you change your own behavior, whatever your own "triggers" might be.

Step 128-Letting The World Do The Work For You

1. Listen and Apply book
 - I. This Explains Everything_ Deep, Beautiful, and Elegant Theories of How the World Works
2. **The world never tells you that you're wrong; it only gives you outcomes.**
3. **Don't force. Don't resist. Have a beginner's mind. Let the world teach you.**
4. **Reality will do a lot of the work for us if we simply align with it. Most of the time we're simply adding friction because we want the world to work in the way we think it should.**
5. **If you don't see the world the way it is, you'll think it works in a way that it doesn't and make terrible mistakes. The key to getting what you want out of life is to identify how the world works and align yourself accordingly. This is hard because we think the world should work the way we see it. The word "should" is important. Because we think the world should work in a way that it doesn't, our approach is suboptimal. What the pupil must learn, if he learns anything at all, is that the world will do most of the work for you, provided you cooperate with it by identifying how it really works and aligning with those realities. If we do not let the world teach us, it teaches us a lesson. Joseph Tussman**
6. When an outcome is not what you want it to be, things get tough. You can ignore the result and continue to think that you're right. This protects your ego. It also carries the risk of your continuing to believe something that isn't true. Alternatively, you can calibrate your believability on the subject at hand by lowering the odds that you're right. For example, maybe you gave yourself an 85 out of 100 for the ability to hold a firm opinion on this subject, and now you lower your score to 75. If the world continues to provide undesirable outcomes, eventually you get the hint and change your beliefs. Finally, you can give up your opinions and just respond to the world as it is. This option is the hardest.
7. You do not create the way the world works, you can only align yourself with it. It takes a lot of work to align ourselves with reality. When we don't get the outcome we're seeking, the last place we look is inside ourselves. Instead, we blame others or

circumstances. If you want to align yourself with reality, you have to work at it and care about it. There are two keys to aligning yourself with how the world really works: accepting feedback and stopping bargaining.

- I. We let people, not results, guide our behavior. The world tries to tell us when we don't see it the way it is. The problem is we don't listen to the world. Instead, we let others tell us what's right and wrong, what works, and what doesn't. Common actions get common results. Most of our actions come from others. We want what they want. Even worse, we employ the same actions to get it. This isn't always wrong. If you're just starting, the quickest path to average is to copy. If you want better results than average, you're going to have to iterate. Doing something different means we might look like a fool, and we do not want to look like a fool. Iterating means trying something new, it means you might fail. Show me a person who's afraid to look bad, and I'll show you a person you can beat every time. If we do what everyone else is doing, we're going to get the same results that everyone else is getting. Different results demand different actions. If you can't really fail, you can't really succeed. Let results, not popularity, determine your actions. If you're doing something that doesn't get you the results you want, try something new. If you're doing something that seems to work, keep doing it. Consistently repeat successful actions.
- II. Bargaining with the world doesn't work. A lot of otherwise smart people know what they're doing isn't getting the results they want, but because they think the world *should* work in a way that it doesn't, they keep repeating them hoping for different results. If you are this person, see it for what it is, and change your actions. The feedback from the world is often painful. Often, it is this very pain that causes us to no longer delude ourselves with how the world should work and accept how it does work. If you can learn to accept the world for how it is, before suffering, you'll go faster and further. Outcome over ego. If you think you know how the world works but you're doing something that gets suboptimal results because it *should* work a different way, you don't really know how the world works. Rational people take feedback from the world. If you want to know how someone sees the world, look at their actions. In the end, it's all your fault. You are accountable for your outcomes. When you take responsibility for your outcomes, you naturally accept feedback from reality. When you get feedback from reality, you adjust your behavior.

- III. As Per Kobe Bryant statement: Trivial things should not be taken your attention. The attentions should be focused on things that is very important. Anything outside of the most important things in life, you should not have time for. You Should love the challenge in life, and always be curious, if you can be at the top , as these greats in that area. Always focus on one thing and not multiple things, this gives an edge and advantage over other people, who focusing on multiple things in life. The World Becomes a library to you, to be better at your craft.: Everything you see whether TV show I saw, Books, Journals, I read, whether discussion, debate I listen, people I talk to. Everything was done to try to learn to become better at the craft your focusing. When you have this point of you, then the world becomes your library to help you to become better at the craft.
- IV. Have the best work ethic on daily basis. This is everyday process, and try to figure it out, the strengths and weaknesses of my position and opposing person position.
- V. Always look at the reality of the situation, and do not let the emotion cloud the situation and the execution. Always be in the present and the moment.
- VI. If you understand the world as it really is, not as you'd wish it to be, you will begin to make better decisions almost immediately. Once you start making better decisions the results compound. Better initial decisions free up your time, reduce your stress, allowing you to spend more time with your family and leave your competition in the dust.
- VII. How can we best understand the world as it is? Acquiring knowledge can be a very daunting task. If you think of the mind as a toolbox, we're only as good as the tools at our disposal. A carpenter doesn't show up to work with an empty toolbox. Not only do they want as many tools in their toolbox as possible, but they want to know how to use them. Having more tools and the knowledge of how to use them means they can tackle more problems. Try as we might, we cannot build a house with only a hammer. If you're a knowledge worker, you're a carpenter. But your tools aren't bought at a store and they don't come in a red box that you carry around. Mental tools are the big ideas from multiple disciplines, and we store them in our mind. And if we have a lot of tools and the knowledge required to wield them properly, we can start to synthesize how the world works and make better decisions when confronted with problems.
- VIII. This is how we understand and deal with reality. The tools you put into your toolbox are Mental Models. Mental models are a framework for understanding

how the world really works. They help you grasp new ideas quickly, identify patterns before anyone else and shift your perspective with ease. Mental Models allow us to make better decisions, scramble out of bad situations, and think critically. If you want to understand reality you must look at a problem in multiple dimensions — how could it be otherwise? Getting to this level of understanding requires having a lot of tools and knowing how to use them. You knew there was a hitch right? We need to change our fast-food diet of information consumption and adopt the healthier diet of knowledge that changes slowly over time. While changing diets isn't easy, it can be incredibly rewarding: more time, less stress, and being better at your job. The costs, however, are short term pain for long-term gain. You must change how you think.

- IX. 2nd Order Thinking. One example of a model we can immediately conceptualize and use to improve our ability to make better decisions is something we can borrow from ecology called second-order thinking. The simple way to conceptualize this is to ask yourself "If I do X, what will happen *after* that?". I sum this up using the ecologist Garrett Hardin's simple question: "And then what?" A lot of people forget about higher order effects — second and third-order effects or higher. I've been in a lot of meetings where decisions are made and very few people think to the second level, let alone the third. Rather, what typically happens is called first conclusion bias. The brain shuts down and stops thinking at the first idea that comes to mind that seems to address the problem as you understand it. We don't often realize that our first thoughts are usually not even our own thoughts. They usually belong to someone else. We understand the sound-byte but we haven't done the hard work of real thinking. After we reach the first conclusion, our minds often shut down. We don't seek evidence that would contradict our conclusion. We don't ask ourselves what the likely result of this solution would be — we don't ask ourselves "And then what?" We don't ask what other solutions might be even *more* optimal. For example, consider a hypothetical organization that decides to change their incentive systems. They come up with a costly new system that requires substantial changes to the current system. Only they don't consider (or even understand) the problems that the *new* system is likely to create. It's possible they've created more problems than they've solved — only now there are *different* problems they must put their head down to solve. Optically, they "reorganize their incentive programs," but practically, they've simply expended energy to stay in place. Another, perhaps more complicated,

example is when a salesman comes into a company and offers you a software program he claims will lower your operating costs and increase your profits. He's got all these beautiful charts on how much more competitive you'll be and how it will improve everything. This is exactly what you need because your compensation is based on increasing profits. You're sold. Then second-order thinking kicks in and you dare to ask how much of those cost savings are going to go to you and how much will eventually end up benefits enjoyed by customers? To a large extent, that depends on the business you're in. However, you can be damn sure the salesman is now knocking on your competitor's door and telling them you just bought their product and if they want to remain competitive they better purchase it too. Eventually, you all have the new software and no one is truly better off. Thus, in the manner of a crowd of people standing on their tip-toes at a parade, all competitors spend the money but none of them win: The salesman wins and the customer wins. We know, thanks to people like Garrett Hardin, Howard Marks, Charlie Munger, Peter Kaufman, and disciplines like ecology, that there are second and third-order effects. This is how the world really works. It just isn't always a comfortable reality. Understanding how the world works isn't easy and it shouldn't be. It's hard work. If it were easy, everyone would do it. And it's not for everyone. Sometimes, if your goal is to maximize utility, you should focus on getting very, very good in a narrow area and becoming an expert, accepting that you will make many mistakes outside of that domain. But for most, it's extremely helpful to understand the forces at play outside of their narrow area of expertise. Because when you think about it, how could reality be anything other than a synthesis of multiple factors? How could it possibly be otherwise?

- X. When our mental models line up with reality, they help us avoid problems. However, they also cause problems when they don't line up with reality as we think something that isn't true.
- XI. We must be open to other perspectives if we truly want to understand the results of our actions. Despite feeling that we've got all the information, if we're on the ship, the fish in the ocean has more he can share. The second flaw is ego. Many of us tend to have too much invested in our opinions of ourselves to see the world's feedback—the feedback we need to update our beliefs about reality. This creates a profound ignorance that keeps us banging our head against the wall over and over again. Our inability to learn from the world because of our ego happens for many reasons, but two are worth mentioning here. First, we're so

afraid about what others will say about us that we fail to put our ideas out there and subject them to criticism. This way we can always be right. Second, if we do put our ideas out there and they are criticized, our ego steps in to protect us. We become invested in defending instead of upgrading our ideas. The third flaw is distance. The further we are from the results of our decisions, the easier it is to keep our current views rather than update them. When you put your hand on a hot stove, you quickly learn the natural consequence. You pay the price for your mistakes. Since you are a pain avoiding creature, you update your view. Before you touch another stove, you check to see if it's hot. But you don't just learn a micro lesson that applies in one situation. Instead, you draw a general abstraction, one that tells you to check before touching anything that could potentially be hot. Organizations over a certain size often remove us from the direct consequences of our decisions. When we make decisions that other people carry out, we are one or more levels removed and may not immediately be able to update our understanding.

T. Why Didn't They Teach Me This in School__ 99 Personal Money Management Principles to Live.

Step 130 - An Investment Approach That Works

There are as many investment strategies as there are investment opportunities. Some are good; many are terrible. Here's the one that I lean on the most when I'm looking for low risk and above average returns.

"The whole secret of investment is to find places where it's safe and wise to non-diversify. It's just that simple." Charlie Munger

Goal: An investment algorithm to lean on hard when it is available. Low-risk, long-duration, above-average returns.

There are many paths to investment heaven (and we've written on the topic before). The diversity of working approaches demonstrates that. However, fundamentally, any useful approach must do three things:

1. It must work in all conceivable financial environments.
2. It must be within the "circle of competence" and "circle of interestingness" of its user.
3. It must meet the moral criteria of its user.

I believe the system below satisfies the first criterion, and allows for all three. A 7-Element Algorithm for Equity Investing.

Everyone Wins

Successful businesses have indefinitely sustainable business systems: owners, employees, customers, suppliers, all content.

Ballast for the Storm

Look for a sustainable balance sheet, given the capricious nature of the world. Past bad events do not predict future bad events. Sometimes inefficient balance sheets allow companies to survive by positioning them for all environments, not just optimizing for one.

Different and Hard to Match

Candidates must occupy a structurally profitable, indefinitely sustainable business niche, allowing for the truism that all moats are subject to being crossed eventually. There must be an element of mystery.

Operational Soundness

Reliable execution of the “blocking and tackling” of operations is a must. Getting this wrong always costs big, and can ruin a good niche.

A Few Simple Variables

Allowing for the difficulty of predicting the future, candidates should have just a few reasonably predictable economic variables that will dominate their outcomes. In the words of Warren Buffett, “There are all kinds of businesses where we have no idea what they’ll earn this year, let alone any future year.” Look for boring investments, sexy is usually complicated and full of competition. Look for what’s staying the same.

Long Runway

You should be able to foresee an indefinite period of growth ahead, through some combination of market creation, market penetration, and pricing power.

Priced Attractively

Stock should be priced so that stock returns $\geq$ business returns, always including a margin for error in forward-looking estimates.

Seemingly missing is the concept of “good management,” but I consider this redundant in light of the first four elements. Any business meeting those criteria is being managed properly, and any investment going 7/7 has a very low probability of failure.

Notice that the word indefinite is used several times. This does not mean the same thing as infinite. There are no infinities in the business world. Indefinite means “as far out as can presently be seen.”

Caution: what psychologists call the “representativeness heuristic” puts us at risk of over-fitting to this or any algorithm. Always be on guard. In the words of Richard Feynman, “Never fool yourself, and remember that you are the easiest person to fool.”

Step 131-Investing: The Rules of the Road

Investing money can seem a little rudderless at times.

One day you hear that stocks are risky and the next that they're indispensable. Some days it seems like stocks only go up and sometimes that they only go down. Real estate used to seem like an automatic path to wealth, and then the housing crisis hit. For the uninitiated, it sometimes seems there are no central truths. And unlike certain fields, we all have to deal with money. We can't "opt out" from financial concerns unless we plan to live in a monastery, and it is useful for all of us to understand the basic ideas.

Investing is not a *science* but a *craft*, and a craftsman needs tools. In the case of investing, the tools are mostly mental. If we accumulate a few simple mental tools, we can start evaluating the claims of experts, salesmen, or simply well-intentioned friends.

The Rules of the Road

(1) The value of an asset depends entirely on the net cash it will generate from now to the hereafter.

This goes for a stock, an apartment house, a convenience store, a bakery, or an iPhone app startup. An asset only has value (in a financial sense) if it can generate net cash flow to its owner. The amount and timing of that cash determines the value of the business. The more cash to be expected and the sooner it's expected to come, the more valuable the asset is today. This is the fundamental truth about investing. Nothing escapes the orbit of future cash flows.

The other determinant of value is interest rates: The average future interest that could have earned if you bought a "risk-free" asset is the opportunity cost of the asset you're considering purchasing today. That risk-free interest rate determines the value of an asset's future cash flows to you today. (Although we don't recommend trying to compute the figure out to three decimal places.) If average risk-free interest rates are 6% over time and I offer you a chance to buy an apartment house that pays you 4% on cost, is that a good buy? You better feel confident that the 4% will grow over time, right? This basic form of reasoning can be applied to all types of cash-producing assets.

This is the thing you should be thinking about when you're instead thinking about what the Fed will be doing or what Jim Cramer said on TV or what the hot industry is or what the CEO of some company had for breakfast. Do you have any idea what the business or property will earn over the next five, ten, or twenty years in relation to what it earns now? This *Grand Unifying Theory* of investing gets discussed surprisingly little.

It also generates some sub-conclusions that aren't always recognized by lay investors and are frequently forgotten by professionals.

(A) What an asset has earned in the past does not determine its value. In stocks, looking at the last ten years of earnings is a useful exercise in trying to understand what type of business you're dealing with, but while it's a good guide, past earnings do not generate value. Future earnings do, and that goes for all types of assets. This means you must develop a view about the future, which we'll address again in point (2) below.

(B) An asset that never earns any net profit after all expenses has no financial value. Please let that sink in. It is common for businesses to obscure this basic fact, and promote all sorts of alternative methodologies with which you're supposed to see value. Book value, EBITDA, number of page views, number of users, brand recognition, and years of managerial experience do not, in and of themselves, tell you about the value of a business or an asset. The bare fact is that an asset must eventually generate net cash flows to its owner which are commensurate with the price paid in order for the investment to be worthwhile. Investing on another basis is, by definition, speculation.

(C) If you have no idea what an asset will earn in the future (at least in a general sense), then you have no idea what it's worth. And if you do not know what the asset is worth, then you have no idea whether you are over-paying or under-paying for it, and as an intellectually honest person, you should consider both possibilities at least equally likely.

(D) Any future cash flows out of an asset must also be subtracted in determining today's value. If a business is going to lose money for 10 years and only then start making it, it's worth a hell of a lot less than one which will make the same amount of money starting this year. This is another idea which gets surprisingly little play in relation to its obvious importance.

(2) Buying a share of stock is a buying share of the underlying business.

Although we're discussing general investment concepts, the stock market needs a bit more attention because of its seemingly abstract nature. No one gets confused as to what they're buying when they invest in a local dry-cleaner. Most fixed income instruments are priced in a fairly straightforward manner. But when it comes to businesses traded on the public exchanges, which we call stocks, all sorts of weird theories abound.

Stocks, for all of their labels and all of the strange fears and speculations around them, are no more than a piece of an underlying business pie. When you buy stock in a business, you are buying the right to the net cash flows that its assets produce. Stocks do not escape the orbit of financial gravity no matter what the Fed is doing or what CNBC is

saying. And buying into an index fund that owns many stocks means that you're now part-owner in all of the underlying businesses; your return comes from the success of their business operations. If American business as a whole keeps on trucking, the index fund will reflect their success, assuming you paid a rational price. That's why averaging into the indexes is such a common recommendation for non-professional investors. Buying individual businesses in the form of stocks carries a heavier burden of proof and much more specialized work.

One corollary to this idea is that stock prices tend to move around much more than intrinsic business values. If you were to take the ten year business record of any of a number of very stable corporations and then guess their high and low stock prices in the same period, you would almost certainly be surprised at the degree of variation. The reason for this can be found in point (3).

(3) Investing in any asset with uncertain cash flows requires an element of speculation about the future.

Discerning an asset's cash flows requires that we make intelligent guesses about a cloudy future. This idea has some deep corollaries:

(A) The more speculation needed to determine the value of the asset, the riskier it is all else equal, due to the higher probability of getting our estimates wrong. In the case of a 1-Year U.S. Treasury bill, we don't have to offer any speculation beyond assuming that the U.S. government will be solvent and paying 12 months from now and that the U.S. dollar will continue to be accepted as legal tender. (If this ceases to be true, we're all in big trouble.)

In the case of a biotechnology startup, on the other hand, our entire valuation is going to be based on speculation. In essence, the whole exercise of valuing such a start-up would be making difficult guesses about the future. The probability that we get all of our guesses correct approaches zero, although if we're correct enough about one or two important factors we might still make money. But we'll need great luck in doing so, whereas with the Treasury bill, we hardly need any luck at all.

(B) Investing in uncertain assets, including any kind of business-based investment like a farm or a technology stock, involves some difficult speculation, so it's easy to predict that at times, investors will get caught up in their enthusiasms and mis-price assets. Charlie Munger has commented that stocks are valued partly like Treasury bonds, with obvious cash flows estimated and discounted at rational rates, and partly like art or collectibles, with speculation that the price will go higher or lower because of popularity, trend, or hope.

The riskiest assets are the ones valued primarily on speculation because of our lack of ability to see into their economic future. That's why a corporate *bond* tends to be less risky than a *stock* — you only need to establish that the corporation will be solvent for the bond to be a good investment, whereas with the stock, you must make much more complicated estimates.

(C) We know from watching horse-race betting, casino gambling, and lottery participation that people are frequently willing to speculate on odds-against bets that can only hurt them financially in the long-run. We observe the same behavior in the stock market and in other markets as well. (There was, for example, a speculative farming boom in the 1980s.) Financial markets cannot be perfectly efficient because of the speculative element. As with (B) above, more uncertain assets tend to have a greater speculative element attached.

(D) Assets with predictable cash flows tend to be inherently lower-risk than ones without predictable cash flows. Let's use two different types of businesses to understand this point. We can be essentially certain that over the next year, Visa and MasterCard will make a tremendous amount of money which is closely related to the amount they made last year — their cash flows are based on the number of transactions made on their cards and the amount of money they collect per transaction. Both elements tend to be extremely stable on a day to day and year to year basis, with a tendency towards growth as new cards make it into circulation. Unless hundreds of millions of people stop using their credit and debit cards or million of merchants find a way to pay a lot less to these intermediaries (who collect very little to start), the businesses will maintain a useful degree of economic predictability. The number of transactions you made on your card last month and the month before pretty closely predicts how much you'll use it this month and the following one.

As we move out further to year 2, we can still be pretty sure that these characteristics will continue to hold, and thus we can predict with useful accuracy the kind of money Visa/Mastercard will make. The same goes for year 3. However, the longer we continue this exercise, the more our accuracy declines. Although things look pretty good this year, next year, and the year after, what about 30 years from now? By then, one can speculate on the possibility of certain changes to the financial system which might affect the economics of Visa/Mastercard. Our earnings estimate 30 years out is certain to be inaccurate even for a predictable business.

The opposite case is Twitter. Twitter has never shown a net profit to its shareholders and has not established a consistent business model which would allow it to do so. Thus, it would be very difficult to say what Twitter's earnings might be in the next year, let alone 30

years from now. On this basis, investing in the common stock of Twitter contains a much larger speculative element than Visa/Mastercard. An investment in Visa/Mastercard *at a fair price in relation to future earnings* can be said to have far less *risk* than an investment in Twitter. Notice that we don't come to this conclusion by saying that Visa/Mastercard are *riskless*, that we can predict their earnings *forever*, or that Twitter will never be a profitable investment. We are simply ranking potential investments on a sliding scale based on the predictability of their future cash flows. Any estimates will be necessarily imprecise, but they still have great value to us as investors.

(4) The price you pay determines the return you get.

Lower prices = higher returns.

You'll often hear fables about how now is the time to invest because "The market has done really well over the past few years" or because "My friend has made a lot of money on this stock, I think it's a good investment," or some similar statement about other kinds of financial assets; real estate properties, oil royalties, McDonald's franchises, etc.

Conversely, one frequently hears things like "That stock's gone way down recently, it seems pretty risky" or "My friend bought a bunch of real estate that went way down, I think real estate is risky" and other notions to that effect.

These thoughts are 180 degrees wrong because they fail to understand the point that low prices create high future returns and that high prices create low future returns. ("High" and "low" being in relation to underlying value.) If a stock trades at 50% of its recent high price, then you are buying the same future cash flows for half the price. If a stock trades at 200% of a recent low price, then the opposite is true; you're getting exactly half the value you would have before.

You should seek to buy assets with future cash earnings you can (roughly) estimate at prices that offer a fair return. The rest is almost always noise.

(5) Everyone has a unique circle of competence which allows them to understand certain things best and other things not at all.

We discussed above in point (3) that certain investment situations are inherently speculative, as with the case of Twitter common stock. But even within the realm of *knowable* investment choices, each investor has his or her own unique circle of competence which they bring to the analysis. In the circle are the things that, through life experience and/or accumulated study, one can fairly evaluate and expect to end up in the right ballpark. Outside of the circle are things we don't have the experience to understand.

Although this point seems simple to the point of banality, it is constantly violated even by smart and financially-savvy people. Many an expert in construction businesses or plumbing businesses or restaurant businesses have tried their hand at buying apartment houses or energy stocks only to find out that their expertise did not carry over. And it is thus for all of us: We are prisoners to our talents, and we're wise to think long and hard about what we really know and don't know.

For example, if you do not have the ability to read financial statements, understand microeconomics, and assess the future underlying cash flows of an individual business, are stocks truly in your circle of competence? If you don't know cap rates from Captain America, is it wise for you to try to get rich buying real estate properties? Unless and until we learn to be honest with ourselves, we will make mistakes that we don't need to make.

Investing does not have to be rocket science. Once you understand the central concepts and begin learning to apply them, all it takes is discipline and intellectual honesty. Anyone can be a successful investor, broadly defined, by sticking to their circle of competence and not straying outside of it, by not speculating when they think they're investing, and by always looking to pay a fair price in relation to what they're buying. These three central tenets, closely followed, can allow any intelligent person to operate safely in the financial world.

Step 132 - Use Rules of Reading for Finance, Economics and Investment

1. Listen, Follow and Apply Rules of Reading of Bible Study, Deep Work, Deep Study, Analysis, Syntopicon and Research For Investment.

A. VERY VERY FAST Reading- Skimming. Pages 47-51.

B. VERY FAST READING- Entertainment.

I. Method 1-Speed Reading. FAST Reading. Pages 59-64.

C. FAST READING: Methods for Basic Knowledge For Deep Work or Bible Study.

I. Method 1-Survey, Question, Read, Recite, Record, Reflect (SQR4). Pages 66-67.

II. Method 2-Use 80/20 Principle For Reading. Pages 68.

III. Method 3-Preview, Question, Read, Summary, Test (PQRST). Page 69.

IV. Method 4-Flip Through Pages and Analyse. Page 70.

V. Method 5-Devotional Bible Study by Using Devotional Books. Pages 71-72.

VI. Method 6-Devotional Bible Read. Pages 73-74.

D. Deep Work, Deep Study, Bible Study or Any Book- SLOW Reading- Complex Text.

- I. Method 1-Chapter Summary Method. Pages 143-147.**
- II. Method 2-Character Quality Method. Pages 148-160.**
- III. Method 3-Thematic Method. Pages 161-163.**
- IV. Method 4-Biographical Method. Pages 164-176.**
- V. Method 5-Topical Method. Pages 177-180.**
- VI. Method 6-Word Study Method. Pages 181-189.**
- VII. Method 7-Book Background Method. Pages 190-194.**
- VIII. Method 8-Book Survey Method. Pages 195-205.**
- IX. Method 9-Chapter Analysis Method. Pages 206-215.**
- X. Method 10-Paragraph Study. Pages 216-229.**
- XI. Method 11-Verse by Verse Analysis Method. Pages 230-234.**
- XII. Method 12-Book Synthesis Method. Pages 235-238.**
- XIII. Method 13-Theological Study Method of Bible Study. Pages 239-245.**
- XIV. Method 14-Studying Bible Prophecy. Pages 246-259.**
- XV. Method 15-Typological Study Method. Pages 260-262.**
- XVI. Method 16- John MacArthur Way Bible Study. Pages 263-268.**
- XVII. Method 17-Inductive Bible Study Method. Pages 269-296.**
- XVIII. Method 18-BIBLICAL HERMENEUTICS. Pages 297-302.**
- XIX. Method 19-Theological Group of Principles. Pages 303-306.**
- XX. Method 20- How To Read A Book Pages 307.**

E. VERY VERY SLOW READING- COMPLEX TEXT. Deep Work, Shallow Work, Bible Study, Analysis of Text, Research, Investigative Journalism, Investigation and Syntopicon, Mixed Method.

- I. Method 21- How To Read A Book By Mortimer Adler Various edition Pages 341.**
- II. Method 22-How To Read A Book For Various Books. Pages 342-600.**
- III. Method 23- Syntopicon Pages 601-642.**
- IV. Method 24-The Craft of Research. Pages 644-882.**
- V. Method 25-Research Books can Be Used. Pages 883-897.**
- VI. Method 26-Investigative Journalism. Pages 898-923.**
- VII. Method 27-Mixed Methods of Rules of Reading. Pages 924-942.**

2. Apply The Books To Investment

Step 133-Thinking, Logic and Mental Model

1. Listen, Follow and Apply Thinking, Logic and Mental Model PART 7

Part 7: Thinking, Logic and Mental Model For Deep Work or Deep Study, Or Bible Study

- 1. Step 57- Slow Down. Pages 1061-1063.**
- 2. Step 58- NOT MULTITASK. Pages 1064.**
- 3. Step 59-You Have Required To Do The Work For Thinking and Applying Mental Tool Models. Pages 1065-1080.**
- 4. Step 60-Why Critical Thinking, Logic, Thinking and Mental Tools Are Important? Pages 1081-1083.**
- 5. Step 61-Intradisciplinary Thinking. Pages 1084-1125.**
- 6. Step 62-Multidisciplinary Thinking. Pages 1126-1168.**
- 7. Step 63-CrossDisciplinary Thinking. Pages 1169-1211.**
- 8. Step 64-Interdisciplinary Thinking. Pages 1212-1254.**
- 9. Step 65-Transdisciplinary Thinking. Pages 1255-1298.**
- 10. Step 66-Journaling. Pages 1299.**
- 11. Step 67-Letting The World Do The Work For You. Pages 1300-1305.**
- 12. Step 68-Journaling. Pages 1306.**
- 13. Step 69-Letting The World Do The Work For You. Pages 1307-1312.**

Step 134-Letting The World Do The Work For You

1. Listen and Apply book
 - I. This Explains Everything_ Deep, Beautiful, and Elegant Theories of How the World Works
2. The world never tells you that you're wrong; it only gives you outcomes.
3. Don't force. Don't resist. Have a beginner's mind. Let the world teach you.
4. **Reality will do a lot of the work for us if we simply align with it.** Most of the time we're simply adding friction because we want the world to work in the way we think it should.
5. If you don't see the world the way it is, you'll think it works in a way that it doesn't and make terrible mistakes. The key to getting what you want out of life is to identify how the world works and align yourself accordingly. This is hard because we think the world should work the way we see it. The word "should" is important. Because we think the world should work in a way that it doesn't, our approach is suboptimal. What the pupil must learn, if he learns anything at all, is that the world will do most of the work for you, provided you cooperate with it by identifying how it really works and aligning with those realities. If we do not let the world teach us, it teaches us a lesson. Joseph Tussman
6. When an outcome is not what you want it to be, things get tough. You can ignore the result and continue to think that you're right. This protects your ego. It also carries the risk of your continuing to believe something that isn't true. Alternatively, you can calibrate your believability on the subject at hand by lowering the odds that you're right. For example, maybe you gave yourself an 85 out of 100 for the ability to hold a firm opinion on this subject, and now you lower your score to 75. If the world continues to provide undesirable outcomes, eventually you get the hint and change your beliefs. Finally, you can give up your opinions and just respond to the world as it is. This option is the hardest.
7. You do not create the way the world works, you can only align yourself with it. It takes a lot of work to align ourselves with reality. When we don't get the outcome we're seeking, the last place we look is inside ourselves. Instead, we blame others or circumstances. If you want to align yourself with reality, you have to work at it and care

about it. There are two keys to aligning yourself with how the world really works: accepting feedback and stopping bargaining.

- I. We let people, not results, guide our behavior. The world tries to tell us when we don't see it the way it is. The problem is we don't listen to the world. Instead, we let others tell us what's right and wrong, what works, and what doesn't. Common actions get common results. Most of our actions come from others. We want what they want. Even worse, we employ the same actions to get it. This isn't always wrong. If you're just starting, the quickest path to average is to copy. If you want better results than average, you're going to have to iterate. Doing something different means we might look like a fool, and we do not want to look like a fool. Iterating means trying something new, it means you might fail. Show me a person who's afraid to look bad, and I'll show you a person you can beat every time. If we do what everyone else is doing, we're going to get the same results that everyone else is getting. Different results demand different actions. If you can't really fail, you can't really succeed. Let results, not popularity, determine your actions. If you're doing something that doesn't get you the results you want, try something new. If you're doing something that seems to work, keep doing it. Consistently repeat successful actions.
- II. Bargaining with the world doesn't work. A lot of otherwise smart people know what they're doing isn't getting the results they want, but because they think the world *should* work in a way that it doesn't, they keep repeating them hoping for different results. If you are this person, see it for what it is, and change your actions. The feedback from the world is often painful. Often, it is this very pain that causes us to no longer delude ourselves with how the world should work and accept how it does work. If you can learn to accept the world for how it is, before suffering, you'll go faster and further. Outcome over ego. If you think you know how the world works but you're doing something that gets suboptimal results because it *should* work a different way, you don't really know how the world works. Rational people take feedback from the world. If you want to know how someone sees the world, look at their actions. In the end, it's all your fault. You are accountable for your outcomes. When you take responsibility for your outcomes, you naturally accept feedback from reality. When you get feedback from reality, you adjust your behavior.
- III. As Per Kobe Bryant statement: Trivial things should not be taken your attention. The attentions should be focused on things that is very important. Anything

outside of the most important things in life, you should not have time for. You Should love the challenge in life, and always be curious, if you can be at the top , as these greats in that area. Always focus on one thing and not multiple things, this gives an edge and advantage over other people, who focusing on multiple things in life. The World Becomes a library to you, to be better at your craft.: Everything you see whether TV show I saw, Books, Journals, I read, whether discussion, debate I listen, people I talk to. Everything was done to try to learn to become better at the craft your focusing. When you have this point of you, then the world becomes your library to help you to become better at the craft.

- IV. Have the best work ethic on daily basis. This is everyday process, and try to figure it out, the strengths and weaknesses of my position and opposing person position.
- V. Always look at the reality of the situation, and do not let the emotion cloud the situation and the execution. Always be in the present and the moment.
- VI. If you understand the world as it really is, not as you'd wish it to be, you will begin to make better decisions almost immediately. Once you start making better decisions the results compound. Better initial decisions free up your time, reduce your stress, allowing you to spend more time with your family and leave your competition in the dust.
- VII. How can we best understand the world as it is? Acquiring knowledge can be a very daunting task. If you think of the mind as a toolbox, we're only as good as the tools at our disposal. A carpenter doesn't show up to work with an empty toolbox. Not only do they want as many tools in their toolbox as possible, but they want to know how to use them. Having more tools and the knowledge of how to use them means they can tackle more problems. Try as we might, we cannot build a house with only a hammer. If you're a knowledge worker, you're a carpenter. But your tools aren't bought at a store and they don't come in a red box that you carry around. Mental tools are the big ideas from multiple disciplines, and we store them in our mind. And if we have a lot of tools and the knowledge required to wield them properly, we can start to synthesize how the world works and make better decisions when confronted with problems.
- VIII. This is how we understand and deal with reality. The tools you put into your toolbox are Mental Models. Mental models are a framework for understanding how the world really works. They help you grasp new ideas quickly, identify patterns before anyone else and shift your perspective with ease. Mental Models

allow us to make better decisions, scramble out of bad situations, and think critically. If you want to understand reality you must look at a problem in multiple dimensions — how could it be otherwise? Getting to this level of understanding requires having a lot of tools and knowing how to use them. You knew there was a hitch right? We need to change our fast-food diet of information consumption and adopt the healthier diet of knowledge that changes slowly over time. While changing diets isn't easy, it can be incredibly rewarding: more time, less stress, and being better at your job. The costs, however, are short term pain for long-term gain. You must change how you think.

- IX. 2nd Order Thinking. One example of a model we can immediately conceptualize and use to improve our ability to make better decisions is something we can borrow from ecology called second-order thinking. The simple way to conceptualize this is to ask yourself “If I do X, what will happen *after* that?”. I sum this up using the ecologist Garrett Hardin's simple question: “*And then what?*” A lot of people forget about higher order effects — second and third-order effects or higher. I've been in a lot of meetings where decisions are made and very few people think to the second level, let alone the third. Rather, what typically happens is called first conclusion bias. The brain shuts down and stops thinking at the first idea that comes to mind that seems to address the problem as you understand it. We don't often realize that our first thoughts are usually not even our own thoughts. They usually belong to someone else. We understand the sound-byte but we haven't done the hard work of real thinking. After we reach the first conclusion, our minds often shut down. We don't seek evidence that would contradict our conclusion. We don't ask ourselves what the likely result of this solution would be — we don't ask ourselves “And then what?” We don't ask what other solutions might be even *more* optimal. For example, consider a hypothetical organization that decides to change their incentive systems. They come up with a costly new system that requires substantial changes to the current system. Only they don't consider (or even understand) the problems that the *new* system is likely to create. It's possible they've created more problems than they've solved — only now there are *different* problems they must put their head down to solve. Optically, they “reorganize their incentive programs,” but practically, they've simply expended energy to stay in place. Another, perhaps more complicated, example is when a salesman comes into a company and offers you a software program he claims will lower your operating costs and increase your profits. He's

got all these beautiful charts on how much more competitive you'll be and how it will improve everything. This is exactly what you need because your compensation is based on increasing profits. You're sold. Then second-order thinking kicks in and you dare to ask how much of those cost savings are going to go to you and how much will eventually end up benefits enjoyed by customers? To a large extent, that depends on the business you're in. However, you can be damn sure the salesman is now knocking on your competitor's door and telling them you just bought their product and if they want to remain competitive they better purchase it too. Eventually, you all have the new software and no one is truly better off. Thus, in the manner of a crowd of people standing on their tip-toes at a parade, all competitors spend the money but none of them win: The salesman wins and the customer wins. We know, thanks to people like Garrett Hardin, Howard Marks, Charlie Munger, Peter Kaufman, and disciplines like ecology, that there are second and third-order effects. This is how the world really works. It just isn't always a comfortable reality. Understanding how the world works isn't easy and it shouldn't be. It's hard work. If it were easy, everyone would do it. And it's not for everyone. Sometimes, if your goal is to maximize utility, you should focus on getting very, very good in a narrow area and becoming an expert, accepting that you will make many mistakes outside of that domain. But for most, it's extremely helpful to understand the forces at play outside of their narrow area of expertise. Because when you think about it, how could reality be anything other than a synthesis of multiple factors? How could it possibly be otherwise?

- X. When our mental models line up with reality, they help us avoid problems. However, they also cause problems when they don't line up with reality as we think something that isn't true.
- XI. We must be open to other perspectives if we truly want to understand the results of our actions. Despite feeling that we've got all the information, if we're on the ship, the fish in the ocean has more he can share. The second flaw is ego. Many of us tend to have too much invested in our opinions of ourselves to see the world's feedback—the feedback we need to update our beliefs about reality. This creates a profound ignorance that keeps us banging our head against the wall over and over again. Our inability to learn from the world because of our ego happens for many reasons, but two are worth mentioning here. First, we're so afraid about what others will say about us that we fail to put our ideas out there and subject them to criticism. This way we can always be right. Second, if we do

put our ideas out there and they are criticized, our ego steps in to protect us. We become invested in defending instead of upgrading our ideas. The third flaw is distance. The further we are from the results of our decisions, the easier it is to keep our current views rather than update them. When you put your hand on a hot stove, you quickly learn the natural consequence. You pay the price for your mistakes. Since you are a pain avoiding creature, you update your view. Before you touch another stove, you check to see if it's hot. But you don't just learn a micro lesson that applies in one situation. Instead, you draw a general abstraction, one that tells you to check before touching anything that could potentially be hot. Organizations over a certain size often remove us from the direct consequences of our decisions. When we make decisions that other people carry out, we are one or more levels removed and may not immediately be able to update our understanding.

*PART 19: Deep Work, Shallow
Work, Thinking, Logic and
Mental Model*

Step 135-Slow Down

- 1. Do Not Rush Any Tasks I will do At Any Time.**
- 2. Listen and Apply Book “The Slow Fix Solve Problems, Work Smarter, and Live Better in a World Addicted to Speed”**
- 3. Listen and Apply Book *In Praise Of Slowness Challenging the Cult of Speed BY Carl Honore.**

- I. We live in a world scarce of understanding and abundant with information. We complain that we never have any free time yet we seek distraction. If work can't distract us, we distract ourselves. We crave perpetual stimulation and motion. We're so busy that our free time comes in 20 second bursts, just long enough for us to read the gist and assume we understand. If we are to synthesize learning and understanding we need time to think.
- II. The modern storm of bits and stimulation, relents only when we sleep. (And then only if we remember to turn off the phone.) Lost in all of this is the art of stillness. We live in a world with more information than ever and yet we understand less. We have come into the belief that the simple act of reading confers understanding. Worse, most of our reading is elementary reading, or skimming — a far cry from syntopical reading, which seems more fertile for the mind willing to do the work.
- III. But that's just it. We don't want, or can't find the time, to do the work that's required to hold an opinion. It's much easier to simply read the opinions of another and let them think for us.
- IV. Understanding comes from focusing, chewing, and relentlessly ragging on a problem. It comes with false starts, dead ends, and frustration. Thinking requires time and space. It's slow. It means saying I don't know. In short, thinking is everything the modern workplace is designed to eradicate.
- V. We're expected to have an opinion about everything and yet our time to think is near zero. We hold more opinions than ever but have less understanding. We don't even understand ourselves. How could it be otherwise?
- VI. As Milan Kundera wrote in his 1996 novella Slowness, “When things happen too fast, nobody can be certain about anything, about anything at all, not even about himself. “In our fast-moving modern world, it always seems that the time-train is

pulling out of the station just as we reach the platform. No matter how fast we go, no matter how cleverly we schedule, there are never enough hours in the day.”

VII. Carl Honore, wrote a book, In Praise of Slowness: Challenging the Cult of Speed, to explore why we’re always in such a rush, what if anything is the cure for time-sickness, and whether it’s desirable to slow down. The book is not an all-out declaration of war against speed. Speed has helped to remake our world in ways that are wonderful and liberating. Who wants to live without the Internet or jet travel? The problem is that our love of speed, our obsession with doing more and more in less and less time, has gone too far; it has turned into an addiction, a kind of idolatry. Even when speed starts to backfire, we invoke the go-faster gospel.

VIII. When we rush, we skim the surface, and fail to make real connections with the world or other people.” Moreover we don’t make connections with ideas. We don’t synthesize. We don’t test theories over time. We don’t play with ideas.

IX. The implications on thinking are fascinating. We are all fast-thinkers now. We have forgotten how to look forward to things, and how to enjoy the moment when they arrive. Restaurants report that hurried diners increasingly pay the bill and order a taxi while eating dessert. Many fans leave sporting events early, no matter how close the score is, simply to steal a march on the traffic. Then there is the curse of multi-tasking. Doing two things at once seems so clever, so efficient, so modern. And yet what it often means is doing two things not very well. Like many people, I read the paper while watching TV— and find that I get less out of both. In this media-drenched, data-rich, channel-surfing, computer-gaming age, we have lost the art of doing nothing, of shutting out the background noise and distractions, of slowing down and simply being alone with our thoughts. Boredom — the word itself hardly existed 150 years ago— is a modern invention. Remove all stimulation, and we fidget, panic and look for something, anything, to do to make use of the time. When did you last see someone just gazing out the window on a train? Everyone is too busy reading the paper, playing video games, listening to iPods, working on the laptop, yammering into mobile phones. Instead of thinking deeply, or letting an idea simmer in the back of the mind, our instinct now is to reach for the nearest sound bite. In modern warfare, correspondents in the field and pundits in the studio spew out instant analyses of events as they occur. Often their insights turn out to be wrong. But that hardly matters nowadays: in the land of speed, the man with the instant response is king. With satellite feeds and twenty-four-hour news channels, the electronic media is dominated by what one

French sociologist dubbed “le fast thinker”— a person who can, without skipping a beat, summon up a glib answer to any question.

- X. Fast eats time. One consequence of fast is that we make poor decision after poor decision. Those decisions don’t go away never to be seen again. It’s not like we make a bad decision and we’re done with it. No, the consequences are much worse. Poor decisions eat time. They come back to haunt you. They create issue after issue. They feed into the perpetual motion machine of busyness. And in a culture where people wear busyness as a badge of honor bad decisions actually lead us to think that we’re doing more.

4. Do The Tasks Slowly, and Step By Step.

5. The Art of Slowing down and Do Not Rush Anything.

- I. The Art of Stillness is a persuasively argued case for the pleasures of slowing down and being in one place. Today we’re going faster and faster in search of contentment and meaning. This is largely a recipe for ensuring we will never be happy. We have the sense, too often, of running at top speed and never being able to catch up.
- II. Too many of us see going nowhere as turning away from something rather than turning towards something.
- III. Going nowhere isn’t about turning your back on the world; it’s about stepping away now and then so that you can see the world more clearly and love it more deeply. “There is nothing either good or bad, but thinking makes it so.”
- IV. The idea behind choosing to sit still long enough to learn about yourself is simple and has been around for ages. Marcus Aurelius and Epictetus reminded us many millennia ago that it’s how we respond to our experiences, not the experiences themselves, which shape us.
- V. The greatest weapon against stress is our ability to choose one thought over another. Part of making better decisions is making time to think. Something that few of us are able to do.
- VI. “Our creations come not when we’re out in the world, gathering impressions, but when we’re sitting still, turning those impressions into sentences.

Step 136-NOT MULTITASK.

1. Of course you can do more than one thing at once. The catch is you can't do more than one thing at once that requires concentration. You can walk and chew gum, but you can't write an email and a report at the same time. When you're doing two things at once that are cognitively demanding, what you're really doing is switching back and forth very quickly from one task to another.
2. There is a mental cost—called a switching cost—to all of this multitasking. But that's not all it makes deep thinking impossible.
3. I think people that multitask pay a huge price. They think they're being extra productive, and I think they're (out of their mind). I use the metaphor of the one-legged man in the ass-kicking contest. I think when you multi-task so much, you don't have time to think about anything deeply. You're giving the world an advantage you shouldn't do. Practically everybody is drifting into that mistake. Concentrating hard on something that is important is. I can't succeed at all without doing it. I did not succeed in life by intelligence. I succeeded because I have a long attention span.
4. It sounds counter-intuitive but if you want to increase discretionary time and reduce stress you need to schedule time to think. The tiny fragments of time many of us find ourselves with have a negative effect on our ability to think deeply about a problem. Furthermore they impede our ability to learn — we stay at a surface level and never move into a deep understanding. Deresiewicz warns: "You simply cannot (think) in bursts of 20 seconds at a time, constantly interrupted by Facebook messages or Twitter tweets, or fiddling with your iPod, or watching something on YouTube."
5. The opposite approach is to focus on a problem or subject and try to achieve a deep fluency. How many of us, however, have time? We don't do the work required to have an opinion. Instead we operate with surface knowledge. We tackle problems with the first thought that comes to mind. Because we make a poor initial decision, we spend countless hours attempting to correct it. No wonder we have no time to think. We're not heeding the advice of Joseph Tussman and letting the world do the work for us.
6. Listen and Apply The Following Books:

A. The Multitasking Mind By Dario Saliveci

Step 137-You Have Required To Do The Work For Deep Work, Thinking, Logic and Mental Model.

1. When Give Opinion on Anything, Do Not Be so Angry and Mean to Others.
2. People Need To Stop Doing By Coming Unprepared To Give Opinion On Any Subject, Without Having Good Idea Of The Literature, and Arguments Written on Topic and Theme Available To Them. The people coming unprepared and not doing any Hard Work To Have an Opinion On The Subject or Topic. When People Coming Overconfidence, which could be resulting in Lack of Preparation, Which Could Lead That Your Position can be Destroyed with Ease. They simply won't do the work required. It's easy to come home, sit on the couch, watch TV, and zone out until bedtime rolls around. But that's not going to help you get smarter.
 - A. People Who Do Not Put The Required Work: The first thing they always do is tell you what they think. When someone has an opinion about everything, they want to share it with you. They often tout stats and research as if they had an imaginary checklist of facts they need to be able to rattle off to establish themselves as an expert in a field they actually know very little about. Because they have an opinion on everything, they are quick to judge others – for their lack of opinions, for their lack of knowledge, for their lack of outrage, and the list goes on.
 - B. People who have opinions about everything barf so much noise that it's hard to find the signal. Your brain has to work overtime to figure out if they did the work to come up with their opinions themselves or if they're simply regurgitating some oped in a newspaper. Over time, opinionated people also end up in their own prisons and they try to take you with them.
 - C. The problem comes from how we see the world. Our opinions are often rooted in how we think the world should work, according to our morals, values, and principles. If we see the world through the lens of our opinions, much of what

happens will not agree with us. This is feedback, and how we respond to this feedback is key.

3. How to Get Smarter Read. A lot. Warren Buffett says, "I just sit in my office and read all day." What does that mean? He estimates that he spends 80% of his working day reading and thinking. When asked how to get smarter, Buffett once held up stacks of paper and said, "Read 500 pages like this every week. That's how knowledge builds up, like compound interest." All of us can build our knowledge, but most of us won't put in the effort. "Go to bed smarter than when you woke up."
4. How Long Does it Take To Prepare:
 - A. Depend on the topic and opponent, and how much he's written.
 - B. If the opponent nothing published, then there was very little preparation to be made because I simply didn't know what to expect.
 - C. On the other hand, if the opponent has published lots of written work and have some videos. Read and what his written and videos and prepare the summaries articles, videos, and have sense where he is coming from. This can take Weeks or Months.

5. Before Preparation. The difference between the people who do the work and the people who just reel off memorized opinions is huge. When you do the work, you can answer the next question. You know when to follow the rules and when they'll get you in trouble. When I did my postgraduate I was surrounded by people who could answer the test questions. They got good grades — actually, they got *great* grades but an odd thing happened after school: a lot of those people couldn't apply their knowledge to problems they hadn't seen before. They were chauffeurs — they knew the memorized answer. They couldn't answer the next question. We're all chauffeurs in some aspects of our lives. This is why understanding your circle of competence is so critical to living a rational life.

I. Circle of Competence:

A. **Circle Of Competence**-Understanding my Circle of Competence helps to avoid problems, identify opportunities for improvement and learn from Others. Circle of Competence is simple: Each of us, through experience or study, has built up useful knowledge on certain areas of the world. Some areas are understood by most of us, while some areas require a lot more specialty to evaluate. For example, most of us have a basic understanding of the economics of a restaurant: You rent or buy space, spend money to outfit the place and then hire employees to seat, serve, cook, and clean. (And, if you don't want to do it yourself, manage.) From there, it's a matter of generating enough traffic and setting the appropriate prices to generate a profit on the food and drinks you serve—after all of your operating expenses have been paid. Though the cuisine, atmosphere, and price points will vary by restaurant, they all have to follow the same economic formula. That basic knowledge, along with some understanding of accounting and a little bit of study, would enable one to evaluate and invest in any number of restaurants and restaurant chains, public or private. It's not all that complicated. Far more important is to honestly define what we do know and stick to those areas. Our circle of competence can be widened, but only slowly and over time. Mistakes are most often made when straying from this discipline. Where should we devote our limited time in life, to achieve the most success? So, the simple takeaway here is clear. If you want to improve your odds of success in life and business, then define the perimeter of your circle of competence, and operate inside. Over time, work to expand that circle

but never fool yourself about where it stands today, and never be afraid to say “I don’t know.”

II. Two Type of Knowledge: The Max Planck and Chauffeur Test

A. The Two Types of Knowledge: The Max Planck and Chauffeur Test: How to distinguish between the two types of knowledge: real knowledge and pretend knowledge.

- The first type of knowledge is real. It can’t be bought. It can’t be copied. If you want real knowledge you need to earn it. One is Planck knowledge, the people who really know. They’ve paid the dues, they have the aptitude. You are going to have the problem in your life of getting the responsibility into the people with the Planck knowledge and away from the people with the chauffeur knowledge. Real knowledge comes when people do the work. The problem is that it’s difficult to separate the two. This is the Batesian Mimicry problem. One way to tease out the difference between Planck and chauffeur knowledge is to ask them why.
- The second type of knowledge is copied. On the surface you know the answer but you lack the understanding to show your work. Then we’ve got chauffeur knowledge. They’ve learned the talk. They may have a big head of hair, they may have fine temper in the voice, they’ll make a hell of an impression. But in the end, all they have is chauffeur knowledge. I think I’ve just described practically every politician in the United States. We have the people who don’t do the work — they pretend. While they’ve learned to put on a good show, they lack understanding. They can’t answer questions that don’t rely on memorization. They can’t explain things without using jargon or vague terms. They have no idea how things interact. They can’t predict the consequences. The problem is that it’s difficult to separate the two. This is the Batesian Mimicry problem. One way to tease out the difference between Planck and chauffeur knowledge is to ask them why.
- How To Distinguish Real Knowledge and Fake Knowledge. With journalists, it is more difficult. Some have acquired true knowledge.

Often they are veteran reporters who have specialized for years in a clearly defined area. They make a serious effort to understand the complexity of a subject and to communicate it. They tend to write long articles that highlight a variety of cases and exceptions. The majority of journalists, however, fall into the category of chauffeur. They conjure up articles off the tops of their heads or, rather, from Google searches. Their texts are one-sided, short, and— often as compensation for their patchy knowledge. The same superficiality is present in business. The larger a company, the more the CEO is expected to possess “star quality.” Dedication, solemnity, and reliability are undervalued, at least at the top. Too often shareholders and business journalists seem to believe that showmanship will deliver better results, which is obviously not the case. One way to guard against this is to understand your circle of competence. Dobelli concludes with some advice worth taking to heart. Be on the lookout for chauffeur knowledge. Do not confuse the company spokesperson, the ringmaster, the newscaster, the schmoozer, the verbiage vendor, or the cliché generator with those who possess true knowledge. How do you recognize the difference? There is a clear indicator: True experts recognize the limits of what they know and what they do not know. If they find themselves outside their circle of competence, they keep quiet or simply say, “I don’t know.” This they utter unapologetically, even with a certain pride. From chauffeurs, we hear every line except this.

III. Batesian Mimicry Problem. Batesian Mimicry: Why Copycats Are Successful.

Mimic and the Real Thing:

- A. "There's two kinds of snakes you come across. There's the Texas Coral Snake, and the Mexican Milk Snake, and they both look exactly alike. The Texas Coral Snake is dangerous, it's venomous, it can kill you in a minute. The Mexican Milk Snake can't do anything to you; it's an impostor." How is it that these two look alike? It's due to a phenomenon called Batesian Mimicry.
- B. In the 1850s, the naturalist Henry Walter Bates found a certain set of butterflies who were clearly *not* of the same species but whose wings looked almost the same to the naked eye. After thinking it over, Bates eventually figured out what was going on: While the butterflies which were toxic to potential predators (the "models") were able to operate freely and relatively unmolested, there had also developed a "mimic" population of butterflies which wasn't toxic at all, yet still went untouched! In fact, biologists eventually figured out that the more toxic and dangerous the "model" was and the more frequently they appeared in the local population, the easier it was for its "mimics" to get by! Predators simply wouldn't take the risk of mixing up the two. If there aren't as many "models" around or they aren't that dangerous, the mimics have a harder time.
- C. This is a wonderful model, and in the practical world we live in, a similar phenomenon abounds: Copycats or "pretenders to the throne" are often very effective, very convincing "mimics" of the true champions. They dress the part, they talk the talk, and they know what buttons to push. But in the end, they are merely chauffeurs. We see a very Batesian effect at work: The more impressive the "model," the more effective its mimics can be in convincing people they too are impressive, and in all the same ways. But for every Warren Buffett (just one by our count), there has been many "future" Warren Buffett's. For every Steve Jobs, there have been many "next" Steve Jobs'. In fact, sometimes even just *appearances* can be quite convincing: now-disgraced Theranos founder Elizabeth Holmes was very fond of wearing a very Steve Jobsian black turtleneck outfit. Because they can be very convincing, we must be wise enough to watch out for Batesian mimicry

— even in ourselves. This brings up an interesting, at times paradoxical, question: Who can best tell the difference between a Coral Snake and its Mimics? The Coral Snake itself. The real thing knows a fake. It's worth taking the time to work on learning all the big ideas you can find, not just the ones you want to learn. In that search, you'll find a host of big winners you didn't even know existed.

6. Preparation:

- A. While we all hold an opinion on almost everything. Have I do the work required to have an opinion on any Subject? Never allow myself to have an opinion on anything that I don't know the other side's argument better than they do. The work required to have an opinion is very hard part, have I avoid it?
 - I. I have to do the reading.
 - II. I have to talk to competent people and understand their arguments.
 - III. Never try to be biased toward any of the side, but question both side of the argument.
 - IV. Do not support any side, until all the facts are put out there, clear and obvious.
 - V. Once known all the facts then analyse both sides of the argument like William Lane Craig.
 - VI. I have to think about the key variables and how they interact over time.
 - VII. I have to listen and chase down arguments that run counter to your views.
 - VIII. I have to think about how you might be fooling yourself.
 - IX. I have to see the issue from multiple perspectives.
 - X. I have to think.
 - XI. I need to become your most intelligent critic and have the intellectual honesty to kill some of your best-loved ideas.
 - XII. Be honest with yourself and open minded. ANALYSE both side of the argument logically and see which is true logically. Means has the clear terms, premises are true, and conclusion follows from premises.
 - XIII. Never say your opinion about anything that requires the analysis of the arguments and facts. Work very bery hard to have an opinion about anything.
 - XIV. Listen very carefully other side and use ancient method *state the opposition argument in my own words and ask him/her if the argument I

stated in my own words represents correctly their argument and if I UNDERSTOOD Correctly their arguments.

XV. Never use cheap shots to win argument, like logical fallacies.

XVI. Debate and discussion is not about just win at any cost, but let other person to think about your arguments and engage with them. Second reason never use in discussion cheap shots toward other person, but be civil. Third reason is win the debate and discussion. Fourth is find the truth.

B. For Affirmative and Negative Case:

- I. Read, analyse, Research, Syntopicon and Investigate Published Work.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of My own Arguments
- II. Read Opponents Books, Articles, Newspapers, Blogs. Reading Published work. What objections he would raise against the topic and prepare the responses for each of these points.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of opponent Arguments.
- III. Watch Video. Watching Videos of the opponent. What objections he would raise against the topic and prepare the responses for each of these points.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of My own Arguments.
- IV. Listen The recording that the opposition made, in which he addresses these issues.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of My own Arguments.
- V. Talk with People who are students in his class, who can tell me, privately, insights into his thinking and character.
- VI. If that sounds like a lot of work, just say, “I don’t have an opinion on that; why don’t you tell me how you got to have such a firm one? It sounds like I could learn something.”
- VII. Another way to get smarter, outside of reading, is to surround yourself with people who are not afraid to challenge your ideas. “Develop into a lifelong self-learner through voracious reading; cultivate curiosity and strive to become a little wiser every day.”

7. Compound Knowledge- Are The Resources I will Choose Concentrating On the Expiring Information or Compound Knowledge?

- I. Are on the Resources providing expiring information?
 - A. Will you care about what you're reading in a month? In a year? In five years?
 - B. Are you focused enough on the same thing to build cumulative knowledge or are you too spread out?
 - C. What do you spend time on that's likely to change in the next few years? What's not likely to change?
 - D. What would need to happen for you to stop outsourcing organisation of information to the computer?
- II. Signs of The Information in the resources are expiring
 - A. First, it's marketed to you.
 - B. Second, lacking details and nuance, it's easily digestible. This is why it's commonly telling you what happened, not why it happened or under what conditions it might happen again
 - C. Third, it won't be relevant in a month or a year. Expiring information is one reason I stopped reading most news. It's a false map.
- III. While most of us focus on consuming information that we won't care about next month, let alone next year, focus on knowledge and companies that change very, very slowly or not at all. And because the information he was learning changed slowly he could compound his knowledge over time.
- IV. Doing his own thinking and vacuums up the details. When we don't think for ourselves it's easy to put the blame on someone else, to "pass the buck" so to speak.
- V. When we consume information that doesn't expire or expires slowly; is very detailed; and we spend time thinking about it not passing the buck, we can match patterns. This is how you learn to see what other people are missing. The longer you do this, the more advantage you get.
- VI. Just like the rest of us, Buffett's dependent on information and knowledge to make great decisions. Unlike most of us, he has a great memory—perhaps because he's not trying to outsource his memory or thinking to others.
- VII. A lot of what the snowball is about the concept of learning, and creating, and the advantage of having the information and knowing it. When I came here today one

of the things that I was thinking is that what you do is so much at the intersection, because retrieving information is different from having it already in your head.

VIII. What you do is different. You work on manipulating how you use the information.

In fact, Warren Buffett and Charlie Munger have the files in their head. That's why they aren't really out there googling all the time looking for, trying to look stuff up, because they already know it.

IX. I think a lot of the work that you do here is helpful to the ordinary person, but Warren Buffett or Charlie Munger don't need it. At the same time, the lesson that they have, which is that learning yourself, making yourself as smart as you can is extremely valid, and not just relying on a library where you can look something up all the time, because a lot of times when you need to make a decision, and you need 50 pieces of information, you need to know it then.

8. The Art of Anticipation of Objections.

- A. Analyse My Arguments, and Scrutinise The arguments by using Rules of Reading.
- B. Analyse the arguments of the opponent. Scrutinise Their arguments by using Rules of Reading.
- C. Analyse My own arguments. Scrutinise My own arguments, and the potential Loopholes in the argument by Use Rules of Reading.
- D. Use Think, Logic, Strategem, Thinking models.
- E. Write.
- F. Prepare The responses to anticipated objections that, I think the opponent will bring up.
- G. Be intellectually Prepared. This means That I need to know my arguments, so well, that nothing new can surprise me. I would also invest lots of time in knowing and know better opposite side arguments. I would read both side of the arguments, and work Hard on analysing the arguments and evidence of both sides. Doing the work required to hold an opinion means you can argue against yourself better than others can. Only then can you say, "I can hold this view because I can't find anyone else who can argue better against my view." Great thinkers, like Charles Darwin, did the work. And it's one of the biggest reasons he's buried at Westminster Abbey. While we all hold an opinion on almost everything. Have I do the work required to have an opinion on any Subject? Never allow myself to have an opinion on anything that I don't know the other side's argument better than they do. The work required to have an opinion is very hard part, have I avoid it? If that sounds like a lot of work, just say, "I don't have an opinion on that; why don't you tell me how you got to have such a firm one? It sounds like I could learn something."
- H. Doing the work required to hold an opinion means you can argue against yourself better than others can. Only then can you say, "I can hold this view because I can't find anyone else who can argue better against my view." Great thinkers, like Charles Darwin, did the work. And it's one of the biggest reasons he's buried at Westminster Abbey.
- I. Doing the work counteracts our natural desire to seek out only information that confirms what we believe we know. When Darwin encountered opinions or facts that ran contrary to his ideas, he endeavored not only to listen but also not to rest

until he could either argue better than his challengers or understand how the fact fit. Darwin did the work. It's wasn't easy, but that's the point.

- J. Have the best work ethic on daily basis. This is everyday process, and try to figure it out, the strengths and weaknesses of my position and opposing person position, This leads to the True Confidence.
- K. As Per Kobe Bryant statement: Trivial things should not be taken your attention. The attentions should be focused on things that is very important. Anything outside of the most important things in life, you should not have time for. You Should love the challenge in life, and always be curious, if you can be at the top , as these greats in that area. Always focus on one thing and not multiple things, this gives an edge and advantage over other people, who focusing on multiple things in life. The World Becomes a library to you, to be better at your craft.: Everything you see whether TV show I saw, Books, Journals, I read, whether discussion, debate I listen, people I talk to. Everything was done to try to learn to become better at the craft your focusing. When you have this point of view, then the world becomes your library to help you to become better at the craft.
- L. I Always need to ask myself: Have I done the work required to have an opinion on any Subject? Never allow myself to have an opinion on anything that I don't know the other side's argument better than they do. The work required to have an opinion is very hard part, have I avoid it? If that sounds like a lot of work, just say, "I don't have an opinion on that; why don't you tell me how you got to have such a firm one? It sounds like I could learn something."
- M. I might need to Suspend my judgement and tell them that I do not have an opinion on this specific Topic.
- N. Never Under Prepare, but Vastly Over Prepare for the Opponent and their arguments and responses
- O. Spend years in preparation, take debate class at the college or university. You need to participate in debates. You need to have mock debates, where someone play role of your opponent, and then you respond to them. You need to do reading and learn how to flow the debates. How to construct affirmative case and negative case. You need to take time to prepare and have enormous preparation.
- P. Memorize the arguments for my case

9. When Dialogue, Discussion, Debate Takes A Place.

A. As Affirmative Speaker, you need to present Prima Facie Case for proposition that is under debate. Prima Facie Case will be one that will establish the truth of proposition you are defending. If I am defending proposition that God Exist, I will want to give 3-5 arguments leading to that Conclusion, that God Exists, and then I will lay those out with great clarity in my opening speech, and say this is the groundwork for the debate. I am not interested in talking about other issues for example if Christianity bad for society Then, I come back to those in every speech over and over again. The goal is to make opponent argue on your grounds. You do not go over to his grounds, and let your audience forget, your affirmative case, rather you reorganise opponent speech, so that you answer his objections in so far as they reply to your arguments, so you may answer them in a very different order than he gave them, because you will be seeing for example: now what answer or response did he have to the cosmological argument, I see two basic responses and then you deal with them.

- Make Briefs, where I have suitable objection, and then have two or three responses to those objections.
- Use The Brief During Exchange with the Opponent. File these Briefs into Folders, and spread These Manila Folders out in front of me on Desk, When I am interacting with the Opponent. Once the opponent Rises his point I just pull These briefs from these folders and never have to think on my feet because I am completely prepared. Key is never have to think on the feet to be so well prepared, that I would have my responses ready for anything he brings up.
- Quote Peer Review Scientific Articles on the topic in support the conclusions.

B. Take Notes While the Opposition is speaking:

- How To Take Notes- Flow Chart. By Taking Notes, I am sure that I am responding to my opponent's arguments and everything he brings up.

I. Make 11-12 Columns on the Pad. Prepare the left column in advance of the communication, debate. The Left Column needs to be filled in, if you starting first. If not, then leave left column as blank.

II. First Left Hand Column Are My Arguments.

III. Second Left Hand Column are Opposition Arguments and Responses to My arguments.

IV. Third Left Column are My Responses to the Opponent responses.

V. Fourth Left Hand Column are My Rebuttal.

VI. Fifth Left Hand Column are Opponent Rebuttal.

VII. Sixth Left Hand Column are my Responses to the Opponent rebuttal.

VIII. Seventh Left Hand Column is the Final My Rebuttal.

IX. Eight Left Hand Column is The opponent Rebuttal.

X. Ninth Left Hand Column is my closing statements.

XI. Tenth Left Hand Column is the opponent closing statements.

XII. Eleventh Left Hand Column is the Cross Examination.

- My Answer.

- Opponent Answer.

- My response to the response of the opponent.

C. Always Remind the audience what are your three to five arguments and what are the responses of the opponent, if any to your arguments.

D. Always allow the opponent allow to lay out his argument without interruption.

E. Take the opponent arguments and put in my own words and correctly represent their argument carefully without misrepresentation.

F. Be Honest.

G. Be Open Minded.

H. Always from Your side be honest and rigorous exchange of arguments and counter Arguments from which me and opponent would benefit.

I. One of good technique is whenever you can quote an opponent against himself, this is powerful device. Have the manuscript, point to the footnote, cite the book, and the quotation and have the page number.

J. Never Take Cheap Shots at the Opponent.

- K. Encourage not just trust someone say so, but demand published peer reviewed articles in support of the positions that one take
- L. Always look at the reality of the situation, and do not let the emotion cloud the situation and the execution. Always be in the present and the moment.

Step 138-Why Critical Thinking, Logic, Thinking and Mental Tools Are Important?

1. After Reading, Analyse, Research and Arguing with the text, then I need to Decide and apply the Logic, Mental Models and thinking model that helps to understand the complexity of the world.
2. If you can think through things better than others, you'll have fewer problems and more free time. If you can't, you're going to spend a lot of time fixing your mistakes. Good decisions make the future easier, bad ones make it harder.
3. The investigators wanted to figure out how today's college students were able to multitask so much more effectively than adults. How do they manage to do it, the researchers asked? The answer, they discovered—and this is by no means what they expected—is that they don't. The enhanced cognitive abilities the investigators expected to find, the mental faculties that enable people to multitask effectively, were simply not there. In other words, people do not multitask effectively. And here's the really surprising finding: the more people multitask, the worse they are, not just at other mental abilities, but at multitasking itself.
4. Multitasking, in short, is not only not thinking, it impairs your ability to think. Thinking means concentrating on one thing long enough to develop an idea about it. Not learning other people's ideas, or memorizing a body of information, however much those may sometimes be useful. Developing your own ideas.
5. The best way to improve your ability to think is to spend large chunks of time thinking. Immersing ourselves in the problem offers insights that can't be gained otherwise. One way to force yourself to slow down and think is to write. Good writing requires good thinking.
6. Good writing, like good thinking, takes time.

7. One heuristic to tell how good someone is at making decisions is by how much time they have. The busiest people are often the ones who make the worst decisions. Not only do they have less time to dedicate to thinking about the problem, but they are often busy correcting poor decisions from the past.
8. Good thinking is expensive. Bad thinking costs a fortune. Rather than accept that good thinking requires time, most people try to bargain with reality. Unfortunately, that is not how the world works. If you want to think better, schedule time to write out your thoughts.
9. Why is important Different type of Thinking to the reality:
 - I. Using Multidisciplinary Thinking to Approach Problems in a Complex World. Complex outcomes in human systems are a tough nut to crack when it comes to deciding what's really true. Any phenomena we might try to explain will have a host of competing theories, many of them seemingly plausible.
 - II. Cross-checks" from a variety of sources of data, developing a 3D view of the landscape he's trying to assess
 - III. So why is it important to be a multidisciplinary thinker? The answer comes from the Austrian philosopher Ludwig Wittgenstein, who said, "To understand is to know what to do." Could there be anything that sounds simpler than that? And yet it's a genius line—"to understand is to know what to do." How many mistakes do you make when you understand something? You don't make any mistakes. Where do mistakes come from? They come from blind spots, a lack of understanding. Why do you need to be multidisciplinary in your thinking? Because as the Japanese proverb says, "The frog in the well knows nothing of the mighty ocean."
 - IV. You may know everything there is to know about your specialty, your silo, your "well," but how are you going to make any good decisions in life—the complex systems of life, the dynamic system of life—if all you know is one well?
 - V. We observe an interesting phenomenon in need of explanation, one we feel capable of exploring. So out of necessity, we must approach the problem in a different way
 - VI. We propose and examine competing hypotheses that would explain the phenomena (set up in a falsifiable way, in harmony with the divide between science and pseudoscience laid out for us by the great Karl Popper).

- VII. Cross-checks” from a variety of sources of data, developing a 3D view of the landscape he’s trying to assess.
- VIII. *Look* we can’t just rely on “plausible narratives” generated by folks like the historians. There are too many possibilities that could be correct. Nor can we rely purely on correlations (i.e., the rise in literacy statistically tracking the decline in violence) — they don’t necessarily offer us a causative explanation. (Does the rise in literacy *cause* less violence, or is it vice versa? Or, does a third factor cause both?) However, if we layer in some other known facts from areas we can experiment on — say, psychology or cognitive neuroscience — we can sometimes establish the causal link we need or, at worst, a better hypothesis of reality.
- IX. We examine a cross-section of: Empirical data relating to the phenomena; sensible qualitative inference (from multiple fields/disciplines, the more fundamental the better), and finally; “Demonstrable” aspects of nature we are nearly certain about, arising from controlled experiment or other rigorous sources of knowledge ranging from engineering to biology to cognitive neuroscience.
- X. What we end up with is not necessarily a bulletproof explanation, but probably the best we can do if we think carefully. A good cross-disciplinary examination with quantitative and qualitative sources coming into equal play, and a good dose of judgment, can be far more rigorous than the gut instinct or plausible nonsense type stories that many of us lazily spout.
- XI. A Word of Caution: Although Pinker’s “multiple vertices” approach to problem solving in complex domains can be powerful, we always have to be on guard for phenomena that we simply cannot explain at our current level of competence: We must have a “too hard” pile when competing explanations come out “too close to call” or we otherwise feel we’re outside of our circle of competence. Always tread carefully and be sure to follow Darwin’s Golden Rule: Contrary facts are more important than confirming ones. Be ready to change your mind, like Darwin, when the facts don’t go your way.
- XII. Using a true multidisciplinary understanding of things, Peter identifies two often overlooked, parabolic “Big Ideas”: 1) Mirrored Reciprocation (go positive and go first) and 2) Compound Interest (being constant). A great “Life Hack” is to simply combine these two into one basic approach to living your life: “Go positive and go first, and be constant in doing it.” There may be no better formula for living the best life you could possibly live.

Step 139-Intradisciplinary Thinking

1. Step 1 Define Intradisciplinary Thinking-Intradisciplinary Thinking. Intradisciplinary Thinking is within a single academic discipline. This is simply thinking within a scope of one academic discipline. Intradisciplinary working is within one discipline. Like a single ingredient, clearly distinguishable. Let's review the process that Pinker has laid out, one that we might think about emulating as we examine the causes of complex phenomena in human systems:

- I. We observe an interesting phenomenon in need of explanation, one we feel capable of exploring.
- II. We propose and examine competing hypotheses that would explain the phenomena (set up in a falsifiable way, in harmony with the divide between science and pseudoscience laid out for us by the great Karl Popper).
- III. We examine a cross-section of: Empirical data relating to the phenomena; sensible qualitative inference (from multiple fields/disciplines, the more fundamental the better), and finally; "Demonstrable" aspects of nature we are nearly certain about, arising from controlled experiment or other rigorous sources of knowledge ranging from engineering to biology to cognitive neuroscience.

IV. Listen and Apply The Following Books:

- **How we can Assess the Level of Interdisciplinarity and Transdisciplinarity of Academic Institutions? By Mahmood Ramezanzade**
- **Detection of Distributed Denial of Service (DDoS) Attacks in IOT Based Monitoring System of Banking Sector Using Machine Learning Models By Muhsmmsf Shafiq**

2. Step 2-Do Work Required to Have an Opinion on Any Topic and Anything.

- I. Most people go through life not really getting any smarter. Why? They simply won't do the work required. It's easy to come home, sit on the couch, watch TV, and zone out until bedtime rolls around. But that's not going to help you get smarter.
- II. You can acquire knowledge if you want it. In fact, there is a simple formula, which if followed is almost certain to make you smarter over time. Simple but not easy. It involves a lot of hard work. "The best thing a human being can do is to help another human being know more."
- III. How to Get Smarter Read. A lot. Warren Buffett says, "I just sit in my office and read all day." What does that mean? He estimates that he spends 80% of his working day reading and thinking. When asked how to get smarter, Buffett once held up stacks of paper and said, "Read 500 pages like this every week. That's how knowledge builds up, like compound interest." All of us can build our knowledge, but most of us won't put in the effort. "Go to bed smarter than when you woke up."
- IV. Knowledge accumulation as an acquired, rather than natural, genius. And he'd give all the credit to the studying;.
- V. The first thing they always do is tell you what they think. When someone has an opinion about everything, they want to share it with you. They often tout stats and research as if they had an imaginary checklist of facts they need to be able to rattle off to establish themselves as an expert in a field they actually know very little about. Because they have an opinion on everything, they are quick to judge others – for their lack of opinions, for their lack of knowledge, for their lack of outrage ... the list goes on.
- VI. People who have opinions about everything barf so much noise that it's hard to find the signal. Your brain has to work overtime to figure out if they did the work to come up with their opinions themselves or if they're simply regurgitating some op-ed in a newspaper. Over time, opinionated people also end up in their own prisons and they try to take you with them.
- VII. The problem comes from how we see the world. Our opinions are often rooted in how we think the world should work, according to our morals, values, and principles. If we see the world through the lens of our opinions, much of what happens will not agree with us. This is feedback, and how we respond to this feedback is key.

VIII. While we all hold an opinion on almost everything. Have I do the work required to have an opinion on any Subject? Never allow myself to have an opinion on anything that I don't know the other side's argument better than they do. The work required to have an opinion is very hard part, have I avoid it?

- I have to do the reading.
- I have to do Thinking and mental model.
- I have to talk to competent people and understand their arguments.
- I have to think about the key variables and how they interact over time.
- I have to listen and chase down arguments that run counter to your views.
- I have to think about how you might be fooling yourself.
- I have to see the issue from multiple perspectives.
- I have to think.
- I need to become your most intelligent critic and have the intellectual honesty to kill some of your best-loved ideas.

IX. If that sounds like a lot of work, just say, "I don't have an opinion on that; why don't you tell me how you got to have such a firm one? It sounds like I could learn something."

X. We all are learning, modifying, or destroying ideas all the time. Rapid destruction of your ideas when the time is right is one of the most valuable qualities you can acquire. You must force yourself to consider arguments on the other side. As Rabbi Moses ben Maimon (1135–1204), commonly known as Maimonides, said: "Teach thy tongue to say I do not know, and thou shalt progress."

XI. Doing the work required to hold an opinion means you can argue against yourself better than others can. Only then can you say, "I can hold this view because I can't find anyone else who can argue better against my view." Great thinkers, like Charles Darwin, did the work. And it's one of the biggest reasons he's buried at Westminster Abbey.

XII. Doing the work counteracts our natural desire to seek out only information that confirms what we believe we know. When Darwin encountered opinions or facts that ran contrary to his ideas, he endeavored not only to listen but also not to rest until he could either argue better than his challengers or understand how the fact fit. Darwin did the work. It's wasn't easy, but that's the point.

XIII. The difference between the people who do the work and the people who just reel off memorized opinions is huge. When you do the work, you can answer the next question. You know when to follow the rules and when they'll get you in trouble. When I did my postgraduate I was surrounded by people who could answer the test questions. They got good grades — actually, they got *great* grades but an odd thing happened after school: a lot of those people couldn't apply their knowledge to problems they hadn't seen before. They were chauffeurs — they knew the memorized answer. They couldn't answer the next question. We're all chauffeurs in some aspects of our lives. This is why understanding your circle of competence is so critical to living a rational life.

- Circle of Competence:

- **Circle Of Competence**-Understanding my Circle of Competence helps to avoid problems, identify opportunities for improvement and learn from Others. Circle of Competence is simple: Each of us, through experience or study, has built up useful knowledge on certain areas of the world. Some areas are understood by most of us, while some areas require a lot more specialty to evaluate. For example, most of us have a basic understanding of the economics of a restaurant: You rent or buy space, spend money to outfit the place and then hire employees to seat, serve, cook, and clean. (And, if you don't want to do it yourself, manage.) From there, it's a matter of generating enough traffic and setting the appropriate prices to generate a profit on the food and drinks you serve —after all of your operating expenses have been paid. Though the cuisine, atmosphere, and price points will vary by restaurant, they all have to follow the same economic formula. That basic knowledge, along with some understanding of accounting and a little bit of study, would enable one to evaluate and invest in any number of restaurants and restaurant chains, public or private. It's not all that complicated. Far more important is to honestly define what we do know and stick to those areas. Our circle of competence can be widened, but only slowly and over time. Mistakes are most often made when straying from this discipline. Where should we devote our limited time in life, to achieve the most success? So, the simple takeaway here is clear. If you want to improve your odds of success in life and business, then define the perimeter of your circle of competence, and operate inside. Over time,

work to expand that circle but never fool yourself about where it stands today, and never be afraid to say “I don’t know.”

- The Two Types of Knowledge: The Max Planck and Chauffeur Test: How to distinguish between the two types of knowledge: real knowledge and pretend knowledge.
 - The first type of knowledge is real. It can’t be bought. It can’t be copied. If you want real knowledge you need to earn it. One is Planck knowledge, the people who really know. They’ve paid the dues, they have the aptitude. You are going to have the problem in your life of getting the responsibility into the people with the Planck knowledge and away from the people with the chauffeur knowledge. Real knowledge comes when people do the work. The problem is that it’s difficult to separate the two. This is the Batesian Mimicry problem. One way to tease out the difference between Planck and chauffeur knowledge is to ask them why.
 - The second type of knowledge is copied. On the surface you know the answer but you lack the understanding to show your work. Then we’ve got chauffeur knowledge. They’ve learned the talk. They may have a big head of hair, they may have fine temper in the voice, they’ll make a hell of an impression. But in the end, all they have is chauffeur knowledge. I think I’ve just described practically every politician in the United States. We have the people who don’t do the work — they pretend. While they’ve learned to put on a good show, they lack understanding. They can’t answer questions that don’t rely on memorization. They can’t explain things without using jargon or vague terms. They have no idea how things interact. They can’t predict the consequences. The problem is that it’s difficult to separate the two. This is the Batesian Mimicry problem. One way to tease out the difference between Planck and chauffeur knowledge is to ask them why.
 - How To Distinguish Real Knowledge and Fake Knowledge. With journalists, it is more difficult. Some have acquired true knowledge. Often they are veteran reporters who have specialized for years in a

clearly defined area. They make a serious effort to understand the complexity of a subject and to communicate it. They tend to write long articles that highlight a variety of cases and exceptions. The majority of journalists, however, fall into the category of chauffeur. They conjure up articles off the tops of their heads or, rather, from Google searches. Their texts are one-sided, short, and— often as compensation for their patchy knowledge. The same superficiality is present in business. The larger a company, the more the CEO is expected to possess “star quality.” Dedication, solemnity, and reliability are undervalued, at least at the top. Too often shareholders and business journalists seem to believe that showmanship will deliver better results, which is obviously not the case. One way to guard against this is to understand your circle of competence. Dobelli concludes with some advice worth taking to heart. Be on the lookout for chauffeur knowledge. Do not confuse the company spokesperson, the ringmaster, the newscaster, the schmoozer, the verbiage vendor, or the cliché generator with those who possess true knowledge. How do you recognize the difference? There is a clear indicator: True experts recognize the limits of what they know and what they do not know. If they find themselves outside their circle of competence, they keep quiet or simply say, “I don’t know.” This they utter unapologetically, even with a certain pride. From chauffeurs, we hear every line except this.

- Batesian Mimicry Problem. Batesian Mimicry: Why Copycats Are Successful. Mimic and the Real Thing:
 - “There’s two kinds of snakes you come across. There’s the Texas Coral Snake, and the Mexican Milk Snake, and they both look exactly alike. The Texas Coral Snake is dangerous, it’s venomous, it can kill you in a minute. The Mexican Milk Snake can’t do anything to you; it’s an impostor.”How is it that these two look alike? It’s due to a phenomenon called Batesian Mimicry.
 - In the 1850s, the naturalist Henry Walter Bates found a certain set of butterflies who were clearly *not* of the same species but whose wings looked almost the same to the naked eye. After thinking it over, Bates eventually figured out what was going on: While the butterflies which were toxic to potential predators (the “models”) were able to operate freely and relatively unmolested, there had also developed a “mimic” population of butterflies which wasn’t toxic at all, yet still went untouched! In fact, biologists eventually figured out that the more toxic and dangerous the “model” was and the more frequently they appeared in the local population, the easier it was for its “mimics” to get by! Predators simply wouldn’t take the risk of mixing up the two. If there aren’t as many “models” around or they aren’t that dangerous, the mimics have a harder time.
 - This is a wonderful model, and in the practical world we live in, a similar phenomenon abounds: Copycats or “pretenders to the throne” are often very effective, very convincing “mimics” of the true champions. They dress the part, they talk the talk, and they know what buttons to push. But in the end, they are merely chauffeurs. We see a very Batesian effect at work: The more impressive the “model,” the more effective its mimics can be in convincing people they too are impressive, and in all the same ways. But for every Warren Buffett (just one by our count), there has been many “future” Warren Buffett’s. For every Steve Jobs, there have been many “next” Steve Jobs’. In fact, sometimes even just *appearances* can be quite convincing: now-disgraced Theranos founder Elizabeth Holmes was very fond of wearing a very Steve Jobsian black turtleneck outfit. Because they can be very convincing, we must be wise enough to watch out for Batesian mimicry

— even in ourselves. This brings up an interesting, at times paradoxical, question: Who can best tell the difference between a Coral Snake and its Mimics? The Coral Snake itself. The real thing knows a fake. It's worth taking the time to work on learning all the big ideas you can find, not just the ones you want to learn. In that search, you'll find a host of big winners you didn't even know existed.

XIV. The ability to destroy your ideas rapidly instead of slowly when the occasion is right is one of the most valuable things. You have to work hard on it. Ask yourself what are the arguments on the other side. It's bad to have an opinion you're proud of if you can't state the arguments for the other side better than your opponents. This is a great mental discipline.

XV. Doing the work means you can't make up your mind with a high degree of confidence right away. Doing the work forces you to challenge your beliefs because you have to argue from both sides. You become the somewhat impartial judge. What's on trial is your opinion. If you want to work with the world rather than against it, one of the major leverage points you can put effort into is how to distinguish between the people who've done the work and those who haven't. The ones who have will pass the Batesian Mimicry Test.

XVI. As Per Kobe Bryant statement: Trivial things should not be taken your attention. The attentions should be focused on things that is very important. Anything outside of the most important things in life, you should not have time for. You Should love the challenge in life, and always be curious, if you can be at the top , as these greats in that area. Always focus on one thing and not multiple things, this gives an edge and advantage over other people, who focusing on multiple things in life. The World Becomes a library to you, to be better at your craft.: Everything you see whether TV show I saw, Books, Journals, I read, whether discussion, debate I listen, people I talk to. Everything was done to try to learn to become better at the craft your focusing. When you have this point of you, then the world becomes your library to help you to become better at the craft.

XVII. Have the best work ethic on daily basis. This is everyday process, and try to figure it out, the strengths and weaknesses of my position and opposing person position.

XVIII. Always look at the reality of the situation, and do not let the emotion cloud the situation and the execution. Always be in the present and the moment.

XIX. We read a lot. I don't know anyone who's wise who doesn't read a lot. But that's not enough: You have to have a temperament to grab ideas and do sensible things. Most people don't grab the right ideas or don't know what to do with them.

XX. Another way to get smarter, outside of reading, is to surround yourself with people who are not afraid to challenge your ideas. "Develop into a lifelong self-learner through voracious reading; cultivate curiosity and strive to become a little wiser every day."

3. Step 3- Slow Down

I. Do Not Rush Thinking Process, and Do it Very Slow.

II. Do Not Rush Any Task I will do At Any Time.

III. Listen and Apply Book “The Slow Fix Solve Problems, Work Smarter, and Live Better in a World Addicted to Speed”

IV. Listen and Apply Book *In Praise Of Slowness Challenging the Cult of Speed BY Carl Honore.

- We live in a world scarce of understanding and abundant with information. We complain that we never have any free time yet we seek distraction. If work can't distract us, we distract ourselves. We crave perpetual stimulation and motion. We're so busy that our free time comes in 20 second bursts, just long enough for us to read the gist and assume we understand. If we are to synthesize learning and understanding we need time to think.
- The modern storm of bits and stimulation, relents only when we sleep. (And then only if we remember to turn off the phone.) Lost in all of this is the art of stillness. We live in a world with more information than ever and yet we understand less. We have come into the belief that the simple act of reading confers understanding. Worse, most of our reading is elementary reading, or skimming — a far cry from syntopical reading, which seems more fertile for the mind willing to do the work.
- But that's just it. We don't want, or can't find the time, to do the work that's required to hold an opinion. It's much easier to simply read the opinions of another and let them think for us.
- Understanding comes from focusing, chewing, and relentlessly ragging on a problem. It comes with false starts, dead ends, and frustration. Thinking requires time and space. It's slow. It means saying I don't know. In short, thinking is everything the modern workplace is designed to eradicate.
- We're expected to have an opinion about everything and yet our time to think is near zero. We hold more opinions than ever but have less understanding. We don't even understand ourselves. How could it be otherwise?
- As Milan Kundera wrote in his 1996 novella Slowness, “When things happen too fast, nobody can be certain about anything, about anything at all, not even about himself. “In our fast-moving modern world, it always

seems that the time-train is pulling out of the station just as we reach the platform. No matter how fast we go, no matter how cleverly we schedule, there are never enough hours in the day.”

- Carl Honore, wrote a book, In Praise of Slowness: Challenging the Cult of Speed, to explore why we’re always in such a rush, what if anything is the cure for time-sickness, and whether it’s desirable to slow down. The book is not an all-out declaration of war against speed. Speed has helped to remake our world in ways that are wonderful and liberating. Who wants to live without the Internet or jet travel? The problem is that our love of speed, our obsession with doing more and more in less and less time, has gone too far; it has turned into an addiction, a kind of idolatry. Even when speed starts to backfire, we invoke the go-faster gospel.
- When we rush, we skim the surface, and fail to make real connections with the world or other people.” Moreover we don’t make connections with ideas. We don’t synthesize. We don’t test theories over time. We don’t play with ideas.
- The implications on thinking are fascinating. We are all fast-thinkers now. We have forgotten how to look forward to things, and how to enjoy the moment when they arrive. Restaurants report that hurried diners increasingly pay the bill and order a taxi while eating dessert. Many fans leave sporting events early, no matter how close the score is, simply to steal a march on the traffic. Then there is the curse of multi-tasking. Doing two things at once seems so clever, so efficient, so modern. And yet what it often means is doing two things not very well. Like many people, I read the paper while watching TV— and find that I get less out of both. In this media-drenched, data-rich, channel-surfing, computer-gaming age, we have lost the art of doing nothing, of shutting out the background noise and distractions, of slowing down and simply being alone with our thoughts. Boredom— the word itself hardly existed 150 years ago— is a modern invention. Remove all stimulation, and we fidget, panic and look for something, anything, to do to make use of the time. When did you last see someone just gazing out the window on a train? Everyone is too busy reading the paper, playing video games, listening to iPods, working on the laptop, yammering into mobile phones. Instead of thinking deeply, or letting an idea simmer in the back of the mind, our instinct now is to reach for the

nearest sound bite. In modern warfare, correspondents in the field and pundits in the studio spew out instant analyses of events as they occur. Often their insights turn out to be wrong. But that hardly matters nowadays: in the land of speed, the man with the instant response is king. With satellite feeds and twenty-four-hour news channels, the electronic media is dominated by what one French sociologist dubbed “le fast thinker”— a person who can, without skipping a beat, summon up a glib answer to any question.

- Fast eats time. One consequence of fast is that we make poor decision after poor decision. Those decisions don’t go away never to be seen again. It’s not like we make a bad decision and we’re done with it. No, the consequences are much worse. Poor decisions eat time. They come back to haunt you. They create issue after issue. They feed into the perpetual motion machine of busyness. And in a culture where people wear busyness as a badge of honor bad decisions actually lead us to think that we’re doing more.

V. Do The Tasks Slowly, and Step By Step.

VI. The Art of Slowing down and Do Not Rush Anything.

- The Art of Stillness is a persuasively argued case for the pleasures of slowing down and being in one place. Today we’re going faster and faster in search of contentment and meaning. This is largely a recipe for ensuring we will never be happy. We have the sense, too often, of running at top speed and never being able to catch up.
- Too many of us see going nowhere as turning away from something rather than turning towards something.
- Going nowhere isn’t about turning your back on the world; it’s about stepping away now and then so that you can see the world more clearly and love it more deeply. “There is nothing either good or bad, but thinking makes it so.”
- The idea behind choosing to sit still long enough to learn about yourself is simple and has been around for ages. Marcus Aurelius and Epictetus reminded us many millennia ago that it’s how we respond to our experiences, not the experiences themselves, which shape us.

- The greatest weapon against stress is our ability to choose one thought over another. Part of making better decisions is making time to think. Something that few of us are able to do.
- “Our creations come not when we’re out in the world, gathering impressions, but when we’re sitting still, turning those impressions into sentences.

4. Step 4- Do not Multitask.

- I. Of course you can do more than one thing at once. The catch is you can’t do more more than one thing at once that requires concentration. You can walk and chew gum, but you can’t write an email and a report at the same time. When you’re doing two things at once that are cognitively demanding, what you’re really doing is switching back and forth very quickly from one task to another.
- II. There is a mental cost—called a switching cost—to all of this multitasking. But that’s not all it makes deep thinking impossible.
- III. I think people that multitask pay a huge price. They think they’re being extra productive, and I think they’re (out of their mind). I use the metaphor of the one-legged man in the ass-kicking contest. I think when you multi-task so much, you don’t have time to think about anything deeply. You’re giving the world an advantage you shouldn’t do. Practically everybody is drifting into that mistake. Concentrating hard on something that is important is. I can’t succeed at all without doing it. I did not succeed in life by intelligence. I succeeded because I have a long attention span.
- IV. It sounds counter-intuitive but if you want to increase discretionary time and reduce stress you need to schedule time to think. The tiny fragments of time many of us find ourselves with have a negative effect on our ability to think deeply about a problem. Furthermore they impede our ability to learn — we stay at a surface level and never move into a deep understanding. Deresiewicz warns: “You simply cannot (think) in bursts of 20 seconds at a time, constantly interrupted by Facebook messages or Twitter tweets, or fiddling with your iPod, or watching something on YouTube.”
- V. The opposite approach is to focus on a problem or subject and try to achieve a deep fluency. How many of us, however, have time? We don’t do the work required to have an opinion. Instead we operate with surface knowledge. We tackle problems with the first thought that comes to mind. Because we make a

poor initial decision, we spend countless hours attempting to correct it. No wonder we have no time to think. We're not heeding the advice of Joseph Tussman and letting the world do the work for us.

VI. Listen and Apply The Following Books:

- **The Multitasking Mind By Dario Saliveci**

5. Step 5-What is Thinking

I. Thinking Rate

- You can't force yourself to think faster. If you try, you're likely to end up making much worse decisions. Here's how to improve the actual quality of your decisions instead of chasing hacks to speed them up.
- When the product of your job is your decisions, you might find yourself wanting to be able to make more decisions more quickly so you can be more productive overall.
- Chasing speed is a flawed approach. Because decisions—at least good ones—don't come out of thin air. They're supported by a lot of thinking.

II. Beyond The Hurry Culture

- Everyone is trying to work faster at all times, and they pressure everyone around them to work faster, too.
- All of these things increase pressure in the work environment and repeatedly reinforce the "hurry up!" message. They make managers feel like they're moving things along faster. That way if work isn't getting done, it's not their fault. But, DeMarco writes, they don't lead to meaningful changes in behavior that make the whole organization more productive. Speeding up often results in poor decisions that create future problems.
- The reason more pressure doesn't mean better productivity is that the rate at which we think is fixed. We can't force ourselves to start making faster decisions right now just because we're faced with an unrealistic deadline. DeMarco writes, *"Think rate is fixed. No matter what you do, no matter how hard you try, you can't pick up the pace of thinking."*

III. Elements of Effective Thinking

- **Understand Deeply.** Don't face complex issues head-on; first understand simple ideas deeply. Clear the clutter and expose what is really important. Be brutally honest about what you know and don't know. Then see what's missing, identify the gaps, and fill them in. Let go of bias, prejudice, and preconceived notions. There are degrees to understanding (it's not just a yes-or-no proposition) and you can always heighten yours. Rock-solid understanding is the foundation for success.
- **Make Mistakes.** Fail to succeed. Intentionally get it wrong to inevitably get it even more right. Mistakes are great teachers — they highlight unforeseen opportunities and holes in your understanding. They also show you which way to turn next, and they ignite your imagination.
- **Raise Questions.** Constantly create questions to clarify and extend your understanding. What's the real question? Working on the wrong questions can waste a lifetime. Ideas are in the air — the right questions will bring them out and help you see connections that otherwise would have been invisible.
- **Follow the Flow of Ideas.** Look back to see where ideas came from and then look ahead to discover where those ideas may lead. A new idea is a beginning, not an end. Ideas are rare— milk them. Following the consequences of small ideas can result in big payoffs. These are the four basic building blocks for effective thinking. The fifth is Change.
- **Change.** The unchanging element is change— by mastering the first four elements, you can change the way you think and learn. You can always improve, grow, and extract more out of your education, yourself, and the way you live your life. Change is the universal constant that allows you to get the most out of living and learning.

6. Step 6-Collect As Many mental models as Possible from diverse domains and academic disciplines That I think is suitable for my situation or Information provided by the Text, Book, Speech etc. Research a broad range of industries to identify mental models that can be integrated and Most Suitable into area of work or focus. In identifying the Great Mental Models we have to look for elementary principles, the ideas from multiple disciplines that form a time tested foundation, these mental models would be from Elementary Mental Models to most Advanced Mental Models. It may seem counterintuitive, to work on developing knowledge that is available to everyone, but the universe works in the same way no matter where you are in it or how you think the universe should be working. What you need is to understand the principles, so that when the details change you are still able to identify what is really going on. Listen and Follow Every Book on Each Mental models.

A. General Mental Models For Thinking.

I. The Great Mental Models Volume 1 By Fs Blog.

- The Map is Not The Territory.
- Circle of Competence.
- The first Principles Thinking.
- Though Experiment.
- Second Order Thinking.
- Probabilistic Thinking.
- Inversion.
- Occam's Razor.
- Hanlon's Razor.
- Supporting Ideas.
- Falsifiability.
- Necessity and Sufficiency.
- Causation vs Correlation.

II. The Great Mental Models Volume 2 By Fs Blog.

- Physics.
 - Relativity.
 - Reciprocity.
 - Thermodynamics.
 - Inertia.

- Friction and Viscosity.
- Velocity
- Leverage.

- Chemistry.
 - Activation Energy.
 - Catalysts.
 - Alloying,

- Biology.
 - Evolution Part One: Natural Selection and Extinction.
 - Evolution Part two: Adaptation Rate and The Red Queen Effect.
 - Supporting Idea: Competition.
 - Ecosystem.
 - Niche.
 - Self Preservation.
 - Replication.
 - Cooperation.
 - Supporting Idea: Dunbar's Number.
 - Hierarchical Organisation.
 - Incentives.
 - Tendency to Minimize energy Output.

III. The Great Mental Models Volume 3 By Fs Blog.

- Systems.
 - Feedback Loops.
 - Equilibrium.
 - Bottlenecks.
 - Scale.
 - Margin of Safety.
 - Churn.
 - Algorithms.
 - Supporting Idea: Complex Adaptive Systems.
 - Critical mass.

- Emergence.
- Supporting Idea: Chaos Dynamics.
- Irreducibility.
- Law of Diminishing Returns.
- Mathematics.
 - Supporting Idea: Distribution.
 - Compounding.
 - Supporting Idea; Network Effect.
 - Sampling.
 - Randomness.
 - Supporting idea: Pareto Principle.
 - Regression to the mean.
 - Multiplying by ZERO.
 - Equivalence.
 - Supporting idea: order of Magnitude.
 - Surface Area.
 - Global and local Maxima.

IV. The Great Mental Models By Tommy Tedford.

- First Principles Mental model.
- Classical Condition.
- Cognitive Biases.
- Circle Of Competence Mental Model.
- Eisenhower Matrix.

7. **Step 7-Getting familiar:** At this starting point, users decide if they can use an existing mental model (maybe one used for another similar product) or if they need to start from scratch. The existing mental model may be void of useful knowledge or worse, contain the wrong knowledge. The core components missing at this stage include an understanding of the language the product uses and the actionable steps needed to complete core tasks.
8. **Step 8-Apply simple criteria to which mental models you use.** When selecting mental models to include into your own latticework, consider whether they support you to better understand yourself and/or the world around you, so you might better effective and impactful action. Also Mental models do two things: they help you assess how things work and they help you make better decisions. Ask some Questions:
 - I. How long has this model been around? As a general rule, mental models which have been around for a long time (such as Occam's razor) will have been subjected to a great deal of scrutiny. Time is an excellent curator, trimming away inefficient ideas. A mental model which is new may not be particularly refined or versatile. Many of our mental models originate from Ancient Greece and Rome, meaning they have to be functional to have survived this long.
 - II. Is it a representation of reality? In other words, does it reflect the real world? Or is it based on abstractions?
 - III. Does this model apply to multiple areas? The more elastic a model is, the more valuable it is to learn about. (Of course, be careful not to apply the model where it doesn't belong. Mind Feynman: "You must not fool yourself, and you're the easiest person to fool.")
 - IV. How did this model originate? Many mental models arise from scientific or mathematical concepts. The more fundamental the domain, the more likely the model is to be true and lasting.
 - V. Is it based on first principles? A first principle is a foundational concept which cannot be deduced from any other concept and must be known.
 - VI. Does it require infinite regress? Infinite regress refers to something which is justified by principles, which themselves require justification by other principles. A model based on infinite regress is likely to

required extensive knowledge of a particular topic, and have minimal real-world application.

9. **Step 9- *Becoming proficient*:** Users begin to understand the language of the situation or text, especially if this language uses technical or unfamiliar vernacular. Understanding terminology and use of product language is one of the first building blocks that form the foundation of the model. This is also when users start to understand the step-by-step procedures required to perform basic operations to get some desired outcome. Here, they are usually learning the bread-and-butter operations of the product so they can receive enough value to motivate them to keep using it. Later, they will be able to build on this knowledge.
10. **Step 10- Make connections between mental models.** We need to know full context and not isolated facts. Rather than holding siloed mental models in your mind, consider how they interact, connect and complement one another.
11. **Step 11-Think, what light the mental model can bring on the situation, idea, text , speech etc.** Do I see the situation, idea, text, speech etc, in the new way? What new way can I see the situation? Does This Makes easier to make a decision in my life?
12. **Step 12- Think very carefully, if each chosen Mental model applicable to situation, idea, text, speech etc.**
13. **Step 13-Use the Chosen Mental Models tool.** The canvas, below, will help you to identify high-value areas where new mental models can make the biggest impact on your work and life. It also provides a simple framework to begin to embed using your chosen models.
14. **Step 14-*Mastering*:** Users build on the core step-by-step tasks they already know, expanding their knowledge to more complex or niche capabilities. If they make it this far they most likely have an accurate understanding of most or all of the language the product uses.
15. **Step 15-Regularly reassess their priorities without fear of changing them.** They don't fall prey to inertia.
16. **Step 16-Be biased toward taking action—not lazily deferring.** If they encounter a mental model they value, they make sure they use it.
17. **Step 17-Be always looking to prove yourselves wrong.** Ego should not get in the way of mental models.

18. Step 18-Accepting that all models are wrong in certain instances is not a license to ignore the facts. As a society, we should search for better answers, look for evidence, and strive to increase the accuracy of our knowledge.

- I. That's not to say all lenses (or models) apply to all problems. They don't. And it's not to say that having more lenses (or models) will be a advantage in all problems. It won't. This is why learning and applying the Great Mental Models is a process that takes some work. But the truth is, most problems are multidimensional, and thus having more lenses often offers significant help with the problems we are facing.**
- II. The more you use them, the more you will be able to build the knowledge of indicators that can trigger the use of the most appropriate model. Using and failing, as long as you acknowledge, reflect, and learn from it, is also how you build your repertoire. You need to be deliberate about choosing the models you will use in a situation. As you use them, a great practice is to record and reflect. That way you can get better at both choosing models and applying them. Take the time to notice how you applied them, what the process was like, and what the results were. Over time you will develop your knowledge of which situations are best tackled through which models. Don't give up on a model if it doesn't help you right away. Learn more about it, and try to figure out exactly why it didn't work. It may be that you have to improve your understanding. Or there were aspects of the situation that you did not consider. Or that your focus was on the wrong variable.**

19. Step 19-After all Analysis, decide what models are the most suitable after all to apply.

20. Step 20-Apply The Mental Model in Real Life or Reality, and let the world do the work for You.

Step 140 - Multidisciplinary Thinking

1. **Step 1 Define Multidisciplinary Thinking.** Multidisciplinary thinking taking combination of various disciplines that maintain their unique perspective unchanged. They share a connection that is not collaborative, but collective and can work together to create a more complicated picture of Reality. The topic of analysis will best expose its different characteristics by exploring different perspectives, using the techniques and observations provided by variety of developed disciplines. Multidisciplinary is characterised within the literature as the least integrative form of integrated research—yet, equally, it is arguably the most attainable. Multidisciplinary features several academic disciplines in a thematically based investigation with multiple goals—essentially, studies “co-exist in a context” . While researchers aim to share knowledge and compare results from the studies there is no attempt to cross boundaries or generate new integrative knowledge. Each member is able to contribute a professional perspective on the issue. Thus the advantage of this approach is that, while the research approaches are disciplinary, the different perspectives on the issue can be gathered into one report for assessment. There is some debate on the extent to which research is coordinated and integrated. While some suggest that multidisciplinary research is coordinated, but not integrated; others contend that there is no coordination, but there is integration at a low level. In general, it is hard to imagine that the research is not, in some way coordinated whilst maintaining even a slight degree of coherence, but it may indeed not be integrated. Multidisciplinary working brings disciplines together so they can learn from each other, drawing on the mix of disciplinary knowledge. It's like a salad: the original ingredients are intact, but the flavours begin to blend. Let's review the process that Pinker has laid out, one that we might think about emulating as we examine the causes of complex phenomena in human systems:

- I. We observe an interesting phenomenon in need of explanation, one we feel capable of exploring.
- II. We propose and examine competing hypotheses that would explain the phenomena (set up in a falsifiable way, in harmony with the divide between science and pseudoscience laid out for us by the great Karl Popper).
- III. We examine a cross-section of: Empirical data relating to the phenomena; sensible qualitative inference (from multiple fields/disciplines, the more fundamental the better), and finally; “Demonstrable” aspects of nature we are nearly certain about, arising from controlled experiment or other rigorous sources of knowledge ranging from engineering to biology to cognitive neuroscience.
- IV. Listen and Apply The Following Books:
 - **How we can Assess the Level of Interdisciplinarity and Transdisciplinarity of Academic Institutions? By Mahmood Ramezanzade**
 - **Detection of Distributed Denial of Service (DDoS) Attacks in IOT Based Monitoring System of Banking Sector Using Machine Learning Models By Muhsmmsf Shafiq**

2. Step 2-Do Work Required to Have an Opinion on Any Topic and Anything.

- I. Most people go through life not really getting any smarter. Why? They simply won't do the work required. It's easy to come home, sit on the couch, watch TV, and zone out until bedtime rolls around. But that's not going to help you get smarter.
- II. You can acquire knowledge if you want it. In fact, there is a simple formula, which if followed is almost certain to make you smarter over time. Simple but not easy. It involves a lot of hard work. "The best thing a human being can do is to help another human being know more."
- III. How to Get Smarter Read. A lot. Warren Buffett says, "I just sit in my office and read all day." What does that mean? He estimates that he spends 80% of his working day reading and thinking. When asked how to get smarter, Buffett once held up stacks of paper and said, "Read 500 pages like this every week. That's how knowledge builds up, like compound interest." All of us can build our knowledge, but most of us won't put in the effort. "Go to bed smarter than when you woke up."
- IV. Knowledge accumulation as an acquired, rather than natural, genius. And he'd give all the credit to the studying;.
- V. The first thing they always do is tell you what they think. When someone has an opinion about everything, they want to share it with you. They often tout stats and research as if they had an imaginary checklist of facts they need to be able to rattle off to establish themselves as an expert in a field they actually know very little about. Because they have an opinion on everything, they are quick to judge others – for their lack of opinions, for their lack of knowledge, for their lack of outrage ... the list goes on.
- VI. People who have opinions about everything barf so much noise that it's hard to find the signal. Your brain has to work overtime to figure out if they did the work to come up with their opinions themselves or if they're simply regurgitating some op-ed in a newspaper. Over time, opinionated people also end up in their own prisons and they try to take you with them.
- VII. The problem comes from how we see the world. Our opinions are often rooted in how we think the world should work, according to our morals, values, and principles. If we see the world through the lens of our opinions, much of what happens will not agree with us. This is feedback, and how we respond to this feedback is key.

VIII. While we all hold an opinion on almost everything. Have I do the work required to have an opinion on any Subject? Never allow myself to have an opinion on anything that I don't know the other side's argument better than they do. The work required to have an opinion is very hard part, have I avoid it?

- I have to do the reading.
- I have to do Thinking and mental model.
- I have to talk to competent people and understand their arguments.
- I have to think about the key variables and how they interact over time.
- I have to listen and chase down arguments that run counter to your views.
- I have to think about how you might be fooling yourself.
- I have to see the issue from multiple perspectives.
- I have to think.
- I need to become your most intelligent critic and have the intellectual honesty to kill some of your best-loved ideas.

IX. If that sounds like a lot of work, just say, "I don't have an opinion on that; why don't you tell me how you got to have such a firm one? It sounds like I could learn something."

X. We all are learning, modifying, or destroying ideas all the time. Rapid destruction of your ideas when the time is right is one of the most valuable qualities you can acquire. You must force yourself to consider arguments on the other side. As Rabbi Moses ben Maimon (1135–1204), commonly known as Maimonides, said: "Teach thy tongue to say I do not know, and thou shalt progress."

XI. Doing the work required to hold an opinion means you can argue against yourself better than others can. Only then can you say, "I can hold this view because I can't find anyone else who can argue better against my view." Great thinkers, like Charles Darwin, did the work. And it's one of the biggest reasons he's buried at Westminster Abbey.

XII. Doing the work counteracts our natural desire to seek out only information that confirms what we believe we know. When Darwin encountered opinions or facts that ran contrary to his ideas, he endeavored not only to listen but also not to rest until he could either argue better than his challengers or understand how the fact fit. Darwin did the work. It's wasn't easy, but that's the point.

XIII. The difference between the people who do the work and the people who just reel off memorized opinions is huge. When you do the work, you can answer the next question. You know when to follow the rules and when they'll get you in trouble. When I did my postgraduate I was surrounded by people who could answer the test questions. They got good grades — actually, they got *great* grades but an odd thing happened after school: a lot of those people couldn't apply their knowledge to problems they hadn't seen before. They were chauffeurs — they knew the memorized answer. They couldn't answer the next question. We're all chauffeurs in some aspects of our lives. This is why understanding your circle of competence is so critical to living a rational life.

- Circle of Competence:

- **Circle Of Competence**-Understanding my Circle of Competence helps to avoid problems, identify opportunities for improvement and learn from Others. Circle of Competence is simple: Each of us, through experience or study, has built up useful knowledge on certain areas of the world. Some areas are understood by most of us, while some areas require a lot more specialty to evaluate. For example, most of us have a basic understanding of the economics of a restaurant: You rent or buy space, spend money to outfit the place and then hire employees to seat, serve, cook, and clean. (And, if you don't want to do it yourself, manage.) From there, it's a matter of generating enough traffic and setting the appropriate prices to generate a profit on the food and drinks you serve —after all of your operating expenses have been paid. Though the cuisine, atmosphere, and price points will vary by restaurant, they all have to follow the same economic formula. That basic knowledge, along with some understanding of accounting and a little bit of study, would enable one to evaluate and invest in any number of restaurants and restaurant chains, public or private. It's not all that complicated. Far more important is to honestly define what we do know and stick to those areas. Our circle of competence can be widened, but only slowly and over time. Mistakes are most often made when straying from this discipline. Where should we devote our limited time in life, to achieve the most success? So, the simple takeaway here is clear. If you want to improve your odds of success in life and business, then define the perimeter of your circle of competence, and operate inside. Over time,

work to expand that circle but never fool yourself about where it stands today, and never be afraid to say “I don’t know.”

- The Two Types of Knowledge: The Max Planck and Chauffeur Test: How to distinguish between the two types of knowledge: real knowledge and pretend knowledge.
 - The first type of knowledge is real. It can’t be bought. It can’t be copied. If you want real knowledge you need to earn it. One is Planck knowledge, the people who really know. They’ve paid the dues, they have the aptitude. You are going to have the problem in your life of getting the responsibility into the people with the Planck knowledge and away from the people with the chauffeur knowledge. Real knowledge comes when people do the work. The problem is that it’s difficult to separate the two. This is the Batesian Mimicry problem. One way to tease out the difference between Planck and chauffeur knowledge is to ask them why.
 - The second type of knowledge is copied. On the surface you know the answer but you lack the understanding to show your work. Then we’ve got chauffeur knowledge. They’ve learned the talk. They may have a big head of hair, they may have fine temper in the voice, they’ll make a hell of an impression. But in the end, all they have is chauffeur knowledge. I think I’ve just described practically every politician in the United States. We have the people who don’t do the work — they pretend. While they’ve learned to put on a good show, they lack understanding. They can’t answer questions that don’t rely on memorization. They can’t explain things without using jargon or vague terms. They have no idea how things interact. They can’t predict the consequences. The problem is that it’s difficult to separate the two. This is the Batesian Mimicry problem. One way to tease out the difference between Planck and chauffeur knowledge is to ask them why.
 - How To Distinguish Real Knowledge and Fake Knowledge. With journalists, it is more difficult. Some have acquired true knowledge. Often they are veteran reporters who have specialized for years in a

clearly defined area. They make a serious effort to understand the complexity of a subject and to communicate it. They tend to write long articles that highlight a variety of cases and exceptions. The majority of journalists, however, fall into the category of chauffeur. They conjure up articles off the tops of their heads or, rather, from Google searches. Their texts are one-sided, short, and— often as compensation for their patchy knowledge. The same superficiality is present in business. The larger a company, the more the CEO is expected to possess “star quality.” Dedication, solemnity, and reliability are undervalued, at least at the top. Too often shareholders and business journalists seem to believe that showmanship will deliver better results, which is obviously not the case. One way to guard against this is to understand your circle of competence. Dobelli concludes with some advice worth taking to heart. Be on the lookout for chauffeur knowledge. Do not confuse the company spokesperson, the ringmaster, the newscaster, the schmoozer, the verbiage vendor, or the cliché generator with those who possess true knowledge. How do you recognize the difference? There is a clear indicator: True experts recognize the limits of what they know and what they do not know. If they find themselves outside their circle of competence, they keep quiet or simply say, “I don’t know.” This they utter unapologetically, even with a certain pride. From chauffeurs, we hear every line except this.

- Batesian Mimicry Problem. Batesian Mimicry: Why Copycats Are Successful. Mimic and the Real Thing:
 - “There’s two kinds of snakes you come across. There’s the Texas Coral Snake, and the Mexican Milk Snake, and they both look exactly alike. The Texas Coral Snake is dangerous, it’s venomous, it can kill you in a minute. The Mexican Milk Snake can’t do anything to you; it’s an impostor.”How is it that these two look alike? It’s due to a phenomenon called Batesian Mimicry.
 - In the 1850s, the naturalist Henry Walter Bates found a certain set of butterflies who were clearly *not* of the same species but whose wings looked almost the same to the naked eye. After thinking it over, Bates eventually figured out what was going on: While the butterflies which were toxic to potential predators (the “models”) were able to operate freely and relatively unmolested, there had also developed a “mimic” population of butterflies which wasn’t toxic at all, yet still went untouched! In fact, biologists eventually figured out that the more toxic and dangerous the “model” was and the more frequently they appeared in the local population, the easier it was for its “mimics” to get by! Predators simply wouldn’t take the risk of mixing up the two. If there aren’t as many “models” around or they aren’t that dangerous, the mimics have a harder time.
 - This is a wonderful model, and in the practical world we live in, a similar phenomenon abounds: Copycats or “pretenders to the throne” are often very effective, very convincing “mimics” of the true champions. They dress the part, they talk the talk, and they know what buttons to push. But in the end, they are merely chauffeurs. We see a very Batesian effect at work: The more impressive the “model,” the more effective its mimics can be in convincing people they too are impressive, and in all the same ways. But for every Warren Buffett (just one by our count), there has been many “future” Warren Buffett’s. For every Steve Jobs, there have been many “next” Steve Jobs’. In fact, sometimes even just *appearances* can be quite convincing: now-disgraced Theranos founder Elizabeth Holmes was very fond of wearing a very Steve Jobsian black turtleneck outfit. Because they can be very convincing, we must be wise enough to watch out for Batesian mimicry

— even in ourselves. This brings up an interesting, at times paradoxical, question: Who can best tell the difference between a Coral Snake and its Mimics? The Coral Snake itself. The real thing knows a fake. It's worth taking the time to work on learning all the big ideas you can find, not just the ones you want to learn. In that search, you'll find a host of big winners you didn't even know existed.

XIV. The ability to destroy your ideas rapidly instead of slowly when the occasion is right is one of the most valuable things. You have to work hard on it. Ask yourself what are the arguments on the other side. It's bad to have an opinion you're proud of if you can't state the arguments for the other side better than your opponents. This is a great mental discipline.

XV. Doing the work means you can't make up your mind with a high degree of confidence right away. Doing the work forces you to challenge your beliefs because you have to argue from both sides. You become the somewhat impartial judge. What's on trial is your opinion. If you want to work with the world rather than against it, one of the major leverage points you can put effort into is how to distinguish between the people who've done the work and those who haven't. The ones who have will pass the Batesian Mimicry Test.

XVI. As Per Kobe Bryant statement: Trivial things should not be taken your attention. The attentions should be focused on things that is very important. Anything outside of the most important things in life, you should not have time for. You Should love the challenge in life, and always be curious, if you can be at the top , as these greats in that area. Always focus on one thing and not multiple things, this gives an edge and advantage over other people, who focusing on multiple things in life. The World Becomes a library to you, to be better at your craft.: Everything you see whether TV show I saw, Books, Journals, I read, whether discussion, debate I listen, people I talk to. Everything was done to try to learn to become better at the craft your focusing. When you have this point of you, then the world becomes your library to help you to become better at the craft.

XVII. Have the best work ethic on daily basis. This is everyday process, and try to figure it out, the strengths and weaknesses of my position and opposing person position.

XVIII. Always look at the reality of the situation, and do not let the emotion cloud the situation and the execution. Always be in the present and the moment.

XIX. We read a lot. I don't know anyone who's wise who doesn't read a lot. But that's not enough: You have to have a temperament to grab ideas and do sensible things. Most people don't grab the right ideas or don't know what to do with them.

XX. Another way to get smarter, outside of reading, is to surround yourself with people who are not afraid to challenge your ideas. "Develop into a lifelong self-learner through voracious reading; cultivate curiosity and strive to become a little wiser every day."

3. Step 3- Slow Down

I. Do Not Rush Thinking Process, and Do it Very Slow.

II. Do Not Rush Any Task I will do At Any Time.

III. Listen and Apply Book “The Slow Fix Solve Problems, Work Smarter, and Live Better in a World Addicted to Speed”

IV. Listen and Apply Book *In Praise Of Slowness Challenging the Cult of Speed BY Carl Honore.

- We live in a world scarce of understanding and abundant with information. We complain that we never have any free time yet we seek distraction. If work can't distract us, we distract ourselves. We crave perpetual stimulation and motion. We're so busy that our free time comes in 20 second bursts, just long enough for us to read the gist and assume we understand. If we are to synthesize learning and understanding we need time to think.
- The modern storm of bits and stimulation, relents only when we sleep. (And then only if we remember to turn off the phone.) Lost in all of this is the art of stillness. We live in a world with more information than ever and yet we understand less. We have come into the belief that the simple act of reading confers understanding. Worse, most of our reading is elementary reading, or skimming — a far cry from syntopical reading, which seems more fertile for the mind willing to do the work.
- But that's just it. We don't want, or can't find the time, to do the work that's required to hold an opinion. It's much easier to simply read the opinions of another and let them think for us.
- Understanding comes from focusing, chewing, and relentlessly ragging on a problem. It comes with false starts, dead ends, and frustration. Thinking requires time and space. It's slow. It means saying I don't know. In short, thinking is everything the modern workplace is designed to eradicate.
- We're expected to have an opinion about everything and yet our time to think is near zero. We hold more opinions than ever but have less understanding. We don't even understand ourselves. How could it be otherwise?
- As Milan Kundera wrote in his 1996 novella Slowness, “When things happen too fast, nobody can be certain about anything, about anything at all, not even about himself. “In our fast-moving modern world, it always

seems that the time-train is pulling out of the station just as we reach the platform. No matter how fast we go, no matter how cleverly we schedule, there are never enough hours in the day.”

- Carl Honore, wrote a book, In Praise of Slowness: Challenging the Cult of Speed, to explore why we’re always in such a rush, what if anything is the cure for time-sickness, and whether it’s desirable to slow down. The book is not an all-out declaration of war against speed. Speed has helped to remake our world in ways that are wonderful and liberating. Who wants to live without the Internet or jet travel? The problem is that our love of speed, our obsession with doing more and more in less and less time, has gone too far; it has turned into an addiction, a kind of idolatry. Even when speed starts to backfire, we invoke the go-faster gospel.
- When we rush, we skim the surface, and fail to make real connections with the world or other people.” Moreover we don’t make connections with ideas. We don’t synthesize. We don’t test theories over time. We don’t play with ideas.
- The implications on thinking are fascinating. We are all fast-thinkers now. We have forgotten how to look forward to things, and how to enjoy the moment when they arrive. Restaurants report that hurried diners increasingly pay the bill and order a taxi while eating dessert. Many fans leave sporting events early, no matter how close the score is, simply to steal a march on the traffic. Then there is the curse of multi-tasking. Doing two things at once seems so clever, so efficient, so modern. And yet what it often means is doing two things not very well. Like many people, I read the paper while watching TV— and find that I get less out of both. In this media-drenched, data-rich, channel-surfing, computer-gaming age, we have lost the art of doing nothing, of shutting out the background noise and distractions, of slowing down and simply being alone with our thoughts. Boredom— the word itself hardly existed 150 years ago— is a modern invention. Remove all stimulation, and we fidget, panic and look for something, anything, to do to make use of the time. When did you last see someone just gazing out the window on a train? Everyone is too busy reading the paper, playing video games, listening to iPods, working on the laptop, yammering into mobile phones. Instead of thinking deeply, or letting an idea simmer in the back of the mind, our instinct now is to reach for the

nearest sound bite. In modern warfare, correspondents in the field and pundits in the studio spew out instant analyses of events as they occur. Often their insights turn out to be wrong. But that hardly matters nowadays: in the land of speed, the man with the instant response is king. With satellite feeds and twenty-four-hour news channels, the electronic media is dominated by what one French sociologist dubbed “le fast thinker”— a person who can, without skipping a beat, summon up a glib answer to any question.

- Fast eats time. One consequence of fast is that we make poor decision after poor decision. Those decisions don’t go away never to be seen again. It’s not like we make a bad decision and we’re done with it. No, the consequences are much worse. Poor decisions eat time. They come back to haunt you. They create issue after issue. They feed into the perpetual motion machine of busyness. And in a culture where people wear busyness as a badge of honor bad decisions actually lead us to think that we’re doing more.

V. Do The Tasks Slowly, and Step By Step.

VI. The Art of Slowing down and Do Not Rush Anything.

- The Art of Stillness is a persuasively argued case for the pleasures of slowing down and being in one place. Today we’re going faster and faster in search of contentment and meaning. This is largely a recipe for ensuring we will never be happy. We have the sense, too often, of running at top speed and never being able to catch up.
- Too many of us see going nowhere as turning away from something rather than turning towards something.
- Going nowhere isn’t about turning your back on the world; it’s about stepping away now and then so that you can see the world more clearly and love it more deeply. “There is nothing either good or bad, but thinking makes it so.”
- The idea behind choosing to sit still long enough to learn about yourself is simple and has been around for ages. Marcus Aurelius and Epictetus reminded us many millennia ago that it’s how we respond to our experiences, not the experiences themselves, which shape us.

- The greatest weapon against stress is our ability to choose one thought over another. Part of making better decisions is making time to think. Something that few of us are able to do.
- “Our creations come not when we’re out in the world, gathering impressions, but when we’re sitting still, turning those impressions into sentences.

4. Step 4- Do not Multitask.

- I. Of course you can do more than one thing at once. The catch is you can’t do more more than one thing at once that requires concentration. You can walk and chew gum, but you can’t write an email and a report at the same time. When you’re doing two things at once that are cognitively demanding, what you’re really doing is switching back and forth very quickly from one task to another.
- II. There is a mental cost—called a switching cost—to all of this multitasking. But that’s not all it makes deep thinking impossible.
- III. I think people that multitask pay a huge price. They think they’re being extra productive, and I think they’re (out of their mind). I use the metaphor of the one-legged man in the ass-kicking contest. I think when you multi-task so much, you don’t have time to think about anything deeply. You’re giving the world an advantage you shouldn’t do. Practically everybody is drifting into that mistake. Concentrating hard on something that is important is. I can’t succeed at all without doing it. I did not succeed in life by intelligence. I succeeded because I have a long attention span.
- IV. It sounds counter-intuitive but if you want to increase discretionary time and reduce stress you need to schedule time to think. The tiny fragments of time many of us find ourselves with have a negative effect on our ability to think deeply about a problem. Furthermore they impede our ability to learn — we stay at a surface level and never move into a deep understanding. Deresiewicz warns: “You simply cannot (think) in bursts of 20 seconds at a time, constantly interrupted by Facebook messages or Twitter tweets, or fiddling with your iPod, or watching something on YouTube.”
- V. The opposite approach is to focus on a problem or subject and try to achieve a deep fluency. How many of us, however, have time? We don’t do the work required to have an opinion. Instead we operate with surface knowledge. We tackle problems with the first thought that comes to mind. Because we make a

poor initial decision, we spend countless hours attempting to correct it. No wonder we have no time to think. We're not heeding the advice of Joseph Tussman and letting the world do the work for us.

VI. Listen and Apply The Following Books:

- **The Multitasking Mind By Dario Saliveci**

5. Step 5-What is Thinking/

I. Thinking Rate

- You can't force yourself to think faster. If you try, you're likely to end up making much worse decisions. Here's how to improve the actual quality of your decisions instead of chasing hacks to speed them up.
- When the product of your job is your decisions, you might find yourself wanting to be able to make more decisions more quickly so you can be more productive overall.
- Chasing speed is a flawed approach. Because decisions—at least good ones—don't come out of thin air. They're supported by a lot of thinking.

II. Beyond The Hurry Culture

- Everyone is trying to work faster at all times, and they pressure everyone around them to work faster, too.
- All of these things increase pressure in the work environment and repeatedly reinforce the "hurry up!" message. They make managers feel like they're moving things along faster. That way if work isn't getting done, it's not their fault. But, DeMarco writes, they don't lead to meaningful changes in behavior that make the whole organization more productive. Speeding up often results in poor decisions that create future problems.
- The reason more pressure doesn't mean better productivity is that the rate at which we think is fixed. We can't force ourselves to start making faster decisions right now just because we're faced with an unrealistic deadline. DeMarco writes, *"Think rate is fixed. No matter what you do, no matter how hard you try, you can't pick up the pace of thinking."*

III. Elements of Effective Thinking

- **Understand Deeply.** Don't face complex issues head-on; first understand simple ideas deeply. Clear the clutter and expose what is really important. Be brutally honest about what you know and don't know. Then see what's missing, identify the gaps, and fill them in. Let go of bias, prejudice, and preconceived notions. There are degrees to understanding (it's not just a yes-or-no proposition) and you can always heighten yours. Rock-solid understanding is the foundation for success.
- **Make Mistakes.** Fail to succeed. Intentionally get it wrong to inevitably get it even more right. Mistakes are great teachers — they highlight unforeseen opportunities and holes in your understanding. They also show you which way to turn next, and they ignite your imagination.
- **Raise Questions.** Constantly create questions to clarify and extend your understanding. What's the real question? Working on the wrong questions can waste a lifetime. Ideas are in the air — the right questions will bring them out and help you see connections that otherwise would have been invisible.
- **Follow the Flow of Ideas.** Look back to see where ideas came from and then look ahead to discover where those ideas may lead. A new idea is a beginning, not an end. Ideas are rare— milk them. Following the consequences of small ideas can result in big payoffs. These are the four basic building blocks for effective thinking. The fifth is Change.
- **Change.** The unchanging element is change— by mastering the first four elements, you can change the way you think and learn. You can always improve, grow, and extract more out of your education, yourself, and the way you live your life. Change is the universal constant that allows you to get the most out of living and learning.

6. Step 6-Collect As Many mental models as Possible from diverse domains and academic disciplines That I think is suitable for my situation or Information provided by the Text, Book, Speech etc. Research a broad range of industries to identify mental models that can be integrated and Most Suitable into area of work or focus. In identifying the Great Mental Models we have to look for elementary principles, the ideas from multiple disciplines that form a time tested foundation, these mental models would be from Elementary Mental Models to most Advanced Mental Models. It may seem counterintuitive, to work on developing knowledge that is available to everyone, but the universe works in the same way no matter where you are in it or how you think the universe should be working. What you need is to understand the principles, so that when the details change you are still able to identify what is really going on. Listen and Follow Every Book on Each Mental models.

A. General Mental Models For Thinking.

I. The Great Mental Models Volume 1 By Fs Blog.

- The Map is Not The Territory.
- Circle of Competence.
- The first Principles Thinking.
- Though Experiment.
- Second Order Thinking.
- Probabilistic Thinking.
- Inversion.
- Occam's Razor.
- Hanlon's Razor.
- Supporting Ideas.
- Falsifiability.
- Necessity and Sufficiency.
- Causation vs Correlation.

II. The Great Mental Models Volume 2 By Fs Blog.

- Physics.
 - Relativity.
 - Reciprocity.
 - Thermodynamics.
 - Inertia.

- Friction and Viscosity.
- Velocity
- Leverage.
- Chemistry.
 - Activation Energy.
 - Catalysts.
 - Alloying,
- Biology.
 - Evolution Part One: Natural Selection and Extinction.
 - Evolution Part two: Adaptation Rate and The Red Queen Effect.
 - Supporting Idea: Competition.
 - Ecosystem.
 - Niche.
 - Self Preservation.
 - Replication.
 - Cooperation.
 - Supporting Idea: Dunbar's Number.
 - Hierarchical Organisation.
 - Incentives.
 - Tendency to Minimize energy Output.

III. The Great Mental Models Volume 3 By Fs Blog.

- Systems.
 - Feedback Loops.
 - Equilibrium.
 - Bottlenecks.
 - Scale.
 - Margin of Safety.
 - Churn.
 - Algorithms.
 - Supporting Idea: Complex Adaptive Systems.
 - Critical mass.

- Emergence.
- Supporting Idea: Chaos Dynamics.
- Irreducibility.
- Law of Diminishing Returns.
- Mathematics.
 - Supporting Idea: Distribution.
 - Compounding.
 - Supporting Idea; Network Effect.
 - Sampling.
 - Randomness.
 - Supporting idea: Pareto Principle.
 - Regression to the mean.
 - Multiplying by ZERO.
 - Equivalence.
 - Supporting idea: order of Magnitude.
 - Surface Area.
 - Global and local Maxima.

IV. The Great Mental Models By Tommy Tedford.

- First Principles Mental model.
- Classical Condition.
- Cognitive Biases.
- Circle Of Competence Mental Model.
- Eisenhower Matrix.

V. 100 Mental Models- Be Rational by Wisdom Theory.

- Philosophy.
 - Meaning Of Life.
 - Stoicism.
 - Cave of plato.
 - Golden Rule.
 - Constructivism.

- **Maths.**
 - Algebra.
 - Permutations and combinations.
 - Algorithms.
 - Scale.
 - Compound interest.
 - Inflection point.

- **Physics.**
 - Scientific Method.
 - Breakpoint.
 - Critical mass.
 - Reciprocity.
 - Velocity.
 - Relativity.
 - Leverage.
 - Newton's Laws of Motion.
 - Chaos Theory.
 - Complex Adaptive Systems.
 - Activation Energy.
 - Laws of Thermodynamics.
 - Heisenberg Uncertainty Principle.

- **Statistics.**
 - Probabilistic thinking.
 - Bayes Theorem.
 - Power Law.
 - Regression to the Mean.
 - Game Theory.
 - Correlation and Causation.
 - Standard Deviation.
 - Law of large numbers.
 - Inversion.
 - Fragility / Robustness / Antifragility.
 - Black Swan.

- **Engineering.**
 - **Redundancy: Margin of safety.**

7. **Step 7-Getting familiar:** At this starting point, users decide if they can use an existing mental model (maybe one used for another similar product) or if they need to start from scratch. The existing mental model may be void of useful knowledge or worse, contain the wrong knowledge. The core components missing at this stage include an understanding of the language the product uses and the actionable steps needed to complete core tasks.
8. **Step 8-Apply simple criteria to which mental models you use.** When selecting mental models to include into your own latticework, consider whether they support you to better understand yourself and/or the world around you, so you might better effective and impactful action. Also Mental models do two things: they help you assess how things work and they help you make better decisions. Ask some Questions:
 - I. How long has this model been around? As a general rule, mental models which have been around for a long time (such as Occam's razor) will have been subjected to a great deal of scrutiny. Time is an excellent curator, trimming away inefficient ideas. A mental model which is new may not be particularly refined or versatile. Many of our mental models originate from Ancient Greece and Rome, meaning they have to be functional to have survived this long.
 - II. Is it a representation of reality? In other words, does it reflect the real world? Or is it based on abstractions?
 - III. Does this model apply to multiple areas? The more elastic a model is, the more valuable it is to learn about. (Of course, be careful not to apply the model where it doesn't belong. Mind Feynman: "You must not fool yourself, and you're the easiest person to fool.")
 - IV. How did this model originate? Many mental models arise from scientific or mathematical concepts. The more fundamental the domain, the more likely the model is to be true and lasting.
 - V. Is it based on first principles? A first principle is a foundational concept which cannot be deduced from any other concept and must be known.
 - VI. Does it require infinite regress? Infinite regress refers to something which is justified by principles, which themselves require justification by other principles. A model based on infinite regress is likely to

required extensive knowledge of a particular topic, and have minimal real-world application.

9. **Step 9- *Becoming proficient*:** Users begin to understand the language of the situation or text, especially if this language uses technical or unfamiliar vernacular. Understanding terminology and use of product language is one of the first building blocks that form the foundation of the model. This is also when users start to understand the step-by-step procedures required to perform basic operations to get some desired outcome. Here, they are usually learning the bread-and-butter operations of the product so they can receive enough value to motivate them to keep using it. Later, they will be able to build on this knowledge.
10. **Step 10- Make connections between mental models.** We need to know full context and not isolated facts. Rather than holding siloed mental models in your mind, consider how they interact, connect and complement one another.
11. **Step 11-Think, what light the mental model can bring on the situation, idea, text , speech etc.** Do I see the situation, idea, text, speech etc, in the new way? What new way can I see the situation? Does This Makes easier to make a decision in my life?
12. **Step 12- Think very carefully, if each chosen Mental model applicable to situation, idea, text, speech etc.**
13. **Step 13-Use the Chosen Mental Models tool.** The canvas, below, will help you to identify high-value areas where new mental models can make the biggest impact on your work and life. It also provides a simple framework to begin to embed using your chosen models.
14. **Step 14-*Mastering*:** Users build on the core step-by-step tasks they already know, expanding their knowledge to more complex or niche capabilities. If they make it this far they most likely have an accurate understanding of most or all of the language the product uses.
15. **Step 15-Regularly reassess their priorities without fear of changing them.** They don't fall prey to inertia.
16. **Step 16-Be biased toward taking action—not lazily deferring.** If they encounter a mental model they value, they make sure they use it.
17. **Step 17-Be always looking to prove yourselves wrong.** Ego should not get in the way of mental models.

18. Step 18-Accepting that all models are wrong in certain instances is not a license to ignore the facts. As a society, we should search for better answers, look for evidence, and strive to increase the accuracy of our knowledge.

- I. That's not to say all lenses (or models) apply to all problems. They don't. And it's not to say that having more lenses (or models) will be a advantage in all problems. It won't. This is why learning and applying the Great Mental Models is a process that takes some work. But the truth is, most problems are multidimensional, and thus having more lenses often offers significant help with the problems we are facing.**
- II. The more you use them, the more you will be able to build the knowledge of indicators that can trigger the use of the most appropriate model. Using and failing, as long as you acknowledge, reflect, and learn from it, is also how you build your repertoire. You need to be deliberate about choosing the models you will use in a situation. As you use them, a great practice is to record and reflect. That way you can get better at both choosing models and applying them. Take the time to notice how you applied them, what the process was like, and what the results were. Over time you will develop your knowledge of which situations are best tackled through which models. Don't give up on a model if it doesn't help you right away. Learn more about it, and try to figure out exactly why it didn't work. It may be that you have to improve your understanding. Or there were aspects of the situation that you did not consider. Or that your focus was on the wrong variable.**

- 19. Step 19-After all Analysis, decide what models are the most suitable after all to apply.**
- 20. Step 20-Apply The Mental Model in Real Life or Reality, and let the world do the work for You.**

Step 141 - CrossDisciplinary Thinking

1. **Step 1 Define CrossDisciplinary Thinking.** Crossdisciplinary thinking applies to several types of cross border interactions, looking at one discipline from an other's viewpoint. You will be working together to move knowledge from one discipline to the other. For example, views from political science are being used in fictional literature to understand political dispute. As part of the current university, cross-disciplinarity has a long background, particularly among disciplines that share borders or those with a shared focus. Physics and astronomy disciplines demonstrate this background. Physics studies a law that determines the universe; these laws extend to non-Earthly contexts (to the best of modern knowledge). Physics and astronomy programs are therefore usually located in the same academic department, providing for cross-disciplinary interaction. Crossdisciplinary working views one discipline from the frame of reference of another. It's like lots of different ingredients on a plate, but without chopping them up and mixing them. Let's review the process that Pinker has laid out, one that we might think about emulating as we examine the causes of complex phenomena in human systems:

- I. We observe an interesting phenomenon in need of explanation, one we feel capable of exploring.
- II. We propose and examine competing hypotheses that would explain the phenomena (set up in a falsifiable way, in harmony with the divide between science and pseudoscience laid out for us by the great Karl Popper).
- III. We examine a cross-section of: Empirical data relating to the phenomena; sensible qualitative inference (from multiple fields/disciplines, the more fundamental the better), and finally; "Demonstrable" aspects of nature we are nearly certain about, arising from controlled experiment or other rigorous sources of knowledge ranging from engineering to biology to cognitive neuroscience.

IV. Listen and Apply The Following Books:

- **How we can Assess the Level of Interdisciplinarity and Transdisciplinarity of Academic Institutions? By Mahmood Ramezanzade**

- **Detection of Distributed Denial of Service (DDoS) Attacks in IOT Based Monitoring System of Banking Sector Using Machine Learning Models By Muhsmmsf Shafiq**

2. Step 2-Do Work Required to Have an Opinion on Any Topic and Anything.

- I. Most people go through life not really getting any smarter. Why? They simply won't do the work required. It's easy to come home, sit on the couch, watch TV, and zone out until bedtime rolls around. But that's not going to help you get smarter.
- II. You can acquire knowledge if you want it. In fact, there is a simple formula, which if followed is almost certain to make you smarter over time. Simple but not easy. It involves a lot of hard work. "The best thing a human being can do is to help another human being know more."
- III. How to Get Smarter Read. A lot. Warren Buffett says, "I just sit in my office and read all day." What does that mean? He estimates that he spends 80% of his working day reading and thinking. When asked how to get smarter, Buffett once held up stacks of paper and said, "Read 500 pages like this every week. That's how knowledge builds up, like compound interest." All of us can build our knowledge, but most of us won't put in the effort. "Go to bed smarter than when you woke up."
- IV. Knowledge accumulation as an acquired, rather than natural, genius. And he'd give all the credit to the studying;.
- V. The first thing they always do is tell you what they think. When someone has an opinion about everything, they want to share it with you. They often tout stats and research as if they had an imaginary checklist of facts they need to be able to rattle off to establish themselves as an expert in a field they actually know very little about. Because they have an opinion on everything, they are quick to judge others – for their lack of opinions, for their lack of knowledge, for their lack of outrage ... the list goes on.
- VI. People who have opinions about everything barf so much noise that it's hard to find the signal. Your brain has to work overtime to figure out if they did the work to come up with their opinions themselves or if they're simply regurgitating some op-ed in a newspaper. Over time, opinionated people also end up in their own prisons and they try to take you with them.
- VII. The problem comes from how we see the world. Our opinions are often rooted in how we think the world should work, according to our morals, values, and principles. If we see the world through the lens of our opinions, much of what happens will not agree with us. This is feedback, and how we respond to this feedback is key.

VIII. While we all hold an opinion on almost everything. Have I do the work required to have an opinion on any Subject? Never allow myself to have an opinion on anything that I don't know the other side's argument better than they do. The work required to have an opinion is very hard part, have I avoid it?

- I have to do the reading.
- I have to do Thinking and mental model.
- I have to talk to competent people and understand their arguments.
- I have to think about the key variables and how they interact over time.
- I have to listen and chase down arguments that run counter to your views.
- I have to think about how you might be fooling yourself.
- I have to see the issue from multiple perspectives.
- I have to think.
- I need to become your most intelligent critic and have the intellectual honesty to kill some of your best-loved ideas.

IX. If that sounds like a lot of work, just say, "I don't have an opinion on that; why don't you tell me how you got to have such a firm one? It sounds like I could learn something."

X. We all are learning, modifying, or destroying ideas all the time. Rapid destruction of your ideas when the time is right is one of the most valuable qualities you can acquire. You must force yourself to consider arguments on the other side. As Rabbi Moses ben Maimon (1135–1204), commonly known as Maimonides, said: "Teach thy tongue to say I do not know, and thou shalt progress."

XI. Doing the work required to hold an opinion means you can argue against yourself better than others can. Only then can you say, "I can hold this view because I can't find anyone else who can argue better against my view." Great thinkers, like Charles Darwin, did the work. And it's one of the biggest reasons he's buried at Westminster Abbey.

XII. Doing the work counteracts our natural desire to seek out only information that confirms what we believe we know. When Darwin encountered opinions or facts that ran contrary to his ideas, he endeavored not only to listen but also not to rest until he could either argue better than his challengers or understand how the fact fit. Darwin did the work. It's wasn't easy, but that's the point.

XIII. The difference between the people who do the work and the people who just reel off memorized opinions is huge. When you do the work, you can answer the next question. You know when to follow the rules and when they'll get you in trouble. When I did my postgraduate I was surrounded by people who could answer the test questions. They got good grades — actually, they got *great* grades but an odd thing happened after school: a lot of those people couldn't apply their knowledge to problems they hadn't seen before. They were chauffeurs — they knew the memorized answer. They couldn't answer the next question. We're all chauffeurs in some aspects of our lives. This is why understanding your circle of competence is so critical to living a rational life.

- Circle of Competence:

- **Circle Of Competence**-Understanding my Circle of Competence helps to avoid problems, identify opportunities for improvement and learn from Others. Circle of Competence is simple: Each of us, through experience or study, has built up useful knowledge on certain areas of the world. Some areas are understood by most of us, while some areas require a lot more specialty to evaluate. For example, most of us have a basic understanding of the economics of a restaurant: You rent or buy space, spend money to outfit the place and then hire employees to seat, serve, cook, and clean. (And, if you don't want to do it yourself, manage.) From there, it's a matter of generating enough traffic and setting the appropriate prices to generate a profit on the food and drinks you serve —after all of your operating expenses have been paid. Though the cuisine, atmosphere, and price points will vary by restaurant, they all have to follow the same economic formula. That basic knowledge, along with some understanding of accounting and a little bit of study, would enable one to evaluate and invest in any number of restaurants and restaurant chains, public or private. It's not all that complicated. Far more important is to honestly define what we do know and stick to those areas. Our circle of competence can be widened, but only slowly and over time. Mistakes are most often made when straying from this discipline. Where should we devote our limited time in life, to achieve the most success? So, the simple takeaway here is clear. If you want to improve your odds of success in life and business, then define the perimeter of your circle of competence, and operate inside. Over time,

work to expand that circle but never fool yourself about where it stands today, and never be afraid to say “I don’t know.”

- The Two Types of Knowledge: The Max Planck and Chauffeur Test: How to distinguish between the two types of knowledge: real knowledge and pretend knowledge.
 - The first type of knowledge is real. It can’t be bought. It can’t be copied. If you want real knowledge you need to earn it. One is Planck knowledge, the people who really know. They’ve paid the dues, they have the aptitude. You are going to have the problem in your life of getting the responsibility into the people with the Planck knowledge and away from the people with the chauffeur knowledge. Real knowledge comes when people do the work. The problem is that it’s difficult to separate the two. This is the Batesian Mimicry problem. One way to tease out the difference between Planck and chauffeur knowledge is to ask them why.
 - The second type of knowledge is copied. On the surface you know the answer but you lack the understanding to show your work. Then we’ve got chauffeur knowledge. They’ve learned the talk. They may have a big head of hair, they may have fine temper in the voice, they’ll make a hell of an impression. But in the end, all they have is chauffeur knowledge. I think I’ve just described practically every politician in the United States. We have the people who don’t do the work — they pretend. While they’ve learned to put on a good show, they lack understanding. They can’t answer questions that don’t rely on memorization. They can’t explain things without using jargon or vague terms. They have no idea how things interact. They can’t predict the consequences. The problem is that it’s difficult to separate the two. This is the Batesian Mimicry problem. One way to tease out the difference between Planck and chauffeur knowledge is to ask them why.
 - How To Distinguish Real Knowledge and Fake Knowledge. With journalists, it is more difficult. Some have acquired true knowledge. Often they are veteran reporters who have specialized for years in a

clearly defined area. They make a serious effort to understand the complexity of a subject and to communicate it. They tend to write long articles that highlight a variety of cases and exceptions. The majority of journalists, however, fall into the category of chauffeur. They conjure up articles off the tops of their heads or, rather, from Google searches. Their texts are one-sided, short, and— often as compensation for their patchy knowledge. The same superficiality is present in business. The larger a company, the more the CEO is expected to possess “star quality.” Dedication, solemnity, and reliability are undervalued, at least at the top. Too often shareholders and business journalists seem to believe that showmanship will deliver better results, which is obviously not the case. One way to guard against this is to understand your circle of competence. Dobelli concludes with some advice worth taking to heart. Be on the lookout for chauffeur knowledge. Do not confuse the company spokesperson, the ringmaster, the newscaster, the schmoozer, the verbiage vendor, or the cliché generator with those who possess true knowledge. How do you recognize the difference? There is a clear indicator: True experts recognize the limits of what they know and what they do not know. If they find themselves outside their circle of competence, they keep quiet or simply say, “I don’t know.” This they utter unapologetically, even with a certain pride. From chauffeurs, we hear every line except this.

- Batesian Mimicry Problem. Batesian Mimicry: Why Copycats Are Successful. Mimic and the Real Thing:
 - “There’s two kinds of snakes you come across. There’s the Texas Coral Snake, and the Mexican Milk Snake, and they both look exactly alike. The Texas Coral Snake is dangerous, it’s venomous, it can kill you in a minute. The Mexican Milk Snake can’t do anything to you; it’s an impostor.”How is it that these two look alike? It’s due to a phenomenon called Batesian Mimicry.
 - In the 1850s, the naturalist Henry Walter Bates found a certain set of butterflies who were clearly *not* of the same species but whose wings looked almost the same to the naked eye. After thinking it over, Bates eventually figured out what was going on: While the butterflies which were toxic to potential predators (the “models”) were able to operate freely and relatively unmolested, there had also developed a “mimic” population of butterflies which wasn’t toxic at all, yet still went untouched! In fact, biologists eventually figured out that the more toxic and dangerous the “model” was and the more frequently they appeared in the local population, the easier it was for its “mimics” to get by! Predators simply wouldn’t take the risk of mixing up the two. If there aren’t as many “models” around or they aren’t that dangerous, the mimics have a harder time.
 - This is a wonderful model, and in the practical world we live in, a similar phenomenon abounds: Copycats or “pretenders to the throne” are often very effective, very convincing “mimics” of the true champions. They dress the part, they talk the talk, and they know what buttons to push. But in the end, they are merely chauffeurs. We see a very Batesian effect at work: The more impressive the “model,” the more effective its mimics can be in convincing people they too are impressive, and in all the same ways. But for every Warren Buffett (just one by our count), there has been many “future” Warren Buffett’s. For every Steve Jobs, there have been many “next” Steve Jobs’. In fact, sometimes even just *appearances* can be quite convincing: now-disgraced Theranos founder Elizabeth Holmes was very fond of wearing a very Steve Jobsian black turtleneck outfit. Because they can be very convincing, we must be wise enough to watch out for Batesian mimicry

— even in ourselves. This brings up an interesting, at times paradoxical, question: Who can best tell the difference between a Coral Snake and its Mimics? The Coral Snake itself. The real thing knows a fake. It's worth taking the time to work on learning all the big ideas you can find, not just the ones you want to learn. In that search, you'll find a host of big winners you didn't even know existed.

XIV. The ability to destroy your ideas rapidly instead of slowly when the occasion is right is one of the most valuable things. You have to work hard on it. Ask yourself what are the arguments on the other side. It's bad to have an opinion you're proud of if you can't state the arguments for the other side better than your opponents. This is a great mental discipline.

XV. Doing the work means you can't make up your mind with a high degree of confidence right away. Doing the work forces you to challenge your beliefs because you have to argue from both sides. You become the somewhat impartial judge. What's on trial is your opinion. If you want to work with the world rather than against it, one of the major leverage points you can put effort into is how to distinguish between the people who've done the work and those who haven't. The ones who have will pass the Batesian Mimicry Test.

XVI. As Per Kobe Bryant statement: Trivial things should not be taken your attention. The attentions should be focused on things that is very important. Anything outside of the most important things in life, you should not have time for. You Should love the challenge in life, and always be curious, if you can be at the top , as these greats in that area. Always focus on one thing and not multiple things, this gives an edge and advantage over other people, who focusing on multiple things in life. The World Becomes a library to you, to be better at your craft.: Everything you see whether TV show I saw, Books, Journals, I read, whether discussion, debate I listen, people I talk to. Everything was done to try to learn to become better at the craft your focusing. When you have this point of you, then the world becomes your library to help you to become better at the craft.

XVII. Have the best work ethic on daily basis. This is everyday process, and try to figure it out, the strengths and weaknesses of my position and opposing person position.

XVIII. Always look at the reality of the situation, and do not let the emotion cloud the situation and the execution. Always be in the present and the moment.

XIX. We read a lot. I don't know anyone who's wise who doesn't read a lot. But that's not enough: You have to have a temperament to grab ideas and do sensible things. Most people don't grab the right ideas or don't know what to do with them.

XX. Another way to get smarter, outside of reading, is to surround yourself with people who are not afraid to challenge your ideas. "Develop into a lifelong self-learner through voracious reading; cultivate curiosity and strive to become a little wiser every day."

3. Step 3- Slow Down

I. Do Not Rush Thinking Process, and Do it Very Slow.

II. Do Not Rush Any Task I will do At Any Time.

III. Listen and Apply Book “The Slow Fix Solve Problems, Work Smarter, and Live Better in a World Addicted to Speed”

IV. Listen and Apply Book *In Praise Of Slowness Challenging the Cult of Speed BY Carl Honore.

- We live in a world scarce of understanding and abundant with information. We complain that we never have any free time yet we seek distraction. If work can't distract us, we distract ourselves. We crave perpetual stimulation and motion. We're so busy that our free time comes in 20 second bursts, just long enough for us to read the gist and assume we understand. If we are to synthesize learning and understanding we need time to think.
- The modern storm of bits and stimulation, relents only when we sleep. (And then only if we remember to turn off the phone.) Lost in all of this is the art of stillness. We live in a world with more information than ever and yet we understand less. We have come into the belief that the simple act of reading confers understanding. Worse, most of our reading is elementary reading, or skimming — a far cry from syntopical reading, which seems more fertile for the mind willing to do the work.
- But that's just it. We don't want, or can't find the time, to do the work that's required to hold an opinion. It's much easier to simply read the opinions of another and let them think for us.
- Understanding comes from focusing, chewing, and relentlessly ragging on a problem. It comes with false starts, dead ends, and frustration. Thinking requires time and space. It's slow. It means saying I don't know. In short, thinking is everything the modern workplace is designed to eradicate.
- We're expected to have an opinion about everything and yet our time to think is near zero. We hold more opinions than ever but have less understanding. We don't even understand ourselves. How could it be otherwise?
- As Milan Kundera wrote in his 1996 novella Slowness, “When things happen too fast, nobody can be certain about anything, about anything at all, not even about himself. “In our fast-moving modern world, it always

seems that the time-train is pulling out of the station just as we reach the platform. No matter how fast we go, no matter how cleverly we schedule, there are never enough hours in the day.”

- Carl Honore, wrote a book, In Praise of Slowness: Challenging the Cult of Speed, to explore why we’re always in such a rush, what if anything is the cure for time-sickness, and whether it’s desirable to slow down. The book is not an all-out declaration of war against speed. Speed has helped to remake our world in ways that are wonderful and liberating. Who wants to live without the Internet or jet travel? The problem is that our love of speed, our obsession with doing more and more in less and less time, has gone too far; it has turned into an addiction, a kind of idolatry. Even when speed starts to backfire, we invoke the go-faster gospel.
- When we rush, we skim the surface, and fail to make real connections with the world or other people.” Moreover we don’t make connections with ideas. We don’t synthesize. We don’t test theories over time. We don’t play with ideas.
- The implications on thinking are fascinating. We are all fast-thinkers now. We have forgotten how to look forward to things, and how to enjoy the moment when they arrive. Restaurants report that hurried diners increasingly pay the bill and order a taxi while eating dessert. Many fans leave sporting events early, no matter how close the score is, simply to steal a march on the traffic. Then there is the curse of multi-tasking. Doing two things at once seems so clever, so efficient, so modern. And yet what it often means is doing two things not very well. Like many people, I read the paper while watching TV— and find that I get less out of both. In this media-drenched, data-rich, channel-surfing, computer-gaming age, we have lost the art of doing nothing, of shutting out the background noise and distractions, of slowing down and simply being alone with our thoughts. Boredom— the word itself hardly existed 150 years ago— is a modern invention. Remove all stimulation, and we fidget, panic and look for something, anything, to do to make use of the time. When did you last see someone just gazing out the window on a train? Everyone is too busy reading the paper, playing video games, listening to iPods, working on the laptop, yammering into mobile phones. Instead of thinking deeply, or letting an idea simmer in the back of the mind, our instinct now is to reach for the

nearest sound bite. In modern warfare, correspondents in the field and pundits in the studio spew out instant analyses of events as they occur. Often their insights turn out to be wrong. But that hardly matters nowadays: in the land of speed, the man with the instant response is king. With satellite feeds and twenty-four-hour news channels, the electronic media is dominated by what one French sociologist dubbed “le fast thinker”— a person who can, without skipping a beat, summon up a glib answer to any question.

- Fast eats time. One consequence of fast is that we make poor decision after poor decision. Those decisions don’t go away never to be seen again. It’s not like we make a bad decision and we’re done with it. No, the consequences are much worse. Poor decisions eat time. They come back to haunt you. They create issue after issue. They feed into the perpetual motion machine of busyness. And in a culture where people wear busyness as a badge of honor bad decisions actually lead us to think that we’re doing more.

V. Do The Tasks Slowly, and Step By Step.

VI. The Art of Slowing down and Do Not Rush Anything.

- The Art of Stillness is a persuasively argued case for the pleasures of slowing down and being in one place. Today we’re going faster and faster in search of contentment and meaning. This is largely a recipe for ensuring we will never be happy. We have the sense, too often, of running at top speed and never being able to catch up.
- Too many of us see going nowhere as turning away from something rather than turning towards something.
- Going nowhere isn’t about turning your back on the world; it’s about stepping away now and then so that you can see the world more clearly and love it more deeply. “There is nothing either good or bad, but thinking makes it so.”
- The idea behind choosing to sit still long enough to learn about yourself is simple and has been around for ages. Marcus Aurelius and Epictetus reminded us many millennia ago that it’s how we respond to our experiences, not the experiences themselves, which shape us.

- The greatest weapon against stress is our ability to choose one thought over another. Part of making better decisions is making time to think. Something that few of us are able to do.
- “Our creations come not when we’re out in the world, gathering impressions, but when we’re sitting still, turning those impressions into sentences.

4. Step 4- Do not Multitask.

- I. Of course you can do more than one thing at once. The catch is you can’t do more more than one thing at once that requires concentration. You can walk and chew gum, but you can’t write an email and a report at the same time. When you’re doing two things at once that are cognitively demanding, what you’re really doing is switching back and forth very quickly from one task to another.
- II. There is a mental cost—called a switching cost—to all of this multitasking. But that’s not all it makes deep thinking impossible.
- III. I think people that multitask pay a huge price. They think they’re being extra productive, and I think they’re (out of their mind). I use the metaphor of the one-legged man in the ass-kicking contest. I think when you multi-task so much, you don’t have time to think about anything deeply. You’re giving the world an advantage you shouldn’t do. Practically everybody is drifting into that mistake. Concentrating hard on something that is important is. I can’t succeed at all without doing it. I did not succeed in life by intelligence. I succeeded because I have a long attention span.
- IV. It sounds counter-intuitive but if you want to increase discretionary time and reduce stress you need to schedule time to think. The tiny fragments of time many of us find ourselves with have a negative effect on our ability to think deeply about a problem. Furthermore they impede our ability to learn — we stay at a surface level and never move into a deep understanding. Deresiewicz warns: “You simply cannot (think) in bursts of 20 seconds at a time, constantly interrupted by Facebook messages or Twitter tweets, or fiddling with your iPod, or watching something on YouTube.”
- V. The opposite approach is to focus on a problem or subject and try to achieve a deep fluency. How many of us, however, have time? We don’t do the work required to have an opinion. Instead we operate with surface knowledge. We tackle problems with the first thought that comes to mind. Because we make a

poor initial decision, we spend countless hours attempting to correct it. No wonder we have no time to think. We're not heeding the advice of Joseph Tussman and letting the world do the work for us.

VI. Listen and Apply The Following Books:

- **The Multitasking Mind By Dario Saliveci**

5. Step 5-What is Thinking/

I. Thinking Rate

- You can't force yourself to think faster. If you try, you're likely to end up making much worse decisions. Here's how to improve the actual quality of your decisions instead of chasing hacks to speed them up.
- When the product of your job is your decisions, you might find yourself wanting to be able to make more decisions more quickly so you can be more productive overall.
- Chasing speed is a flawed approach. Because decisions—at least good ones—don't come out of thin air. They're supported by a lot of thinking.

II. Beyond The Hurry Culture

- Everyone is trying to work faster at all times, and they pressure everyone around them to work faster, too.
- All of these things increase pressure in the work environment and repeatedly reinforce the "hurry up!" message. They make managers feel like they're moving things along faster. That way if work isn't getting done, it's not their fault. But, DeMarco writes, they don't lead to meaningful changes in behavior that make the whole organization more productive. Speeding up often results in poor decisions that create future problems.
- The reason more pressure doesn't mean better productivity is that the rate at which we think is fixed. We can't force ourselves to start making faster decisions right now just because we're faced with an unrealistic deadline. DeMarco writes, *"Think rate is fixed. No matter what you do, no matter how hard you try, you can't pick up the pace of thinking."*

III. Elements of Effective Thinking

- **Understand Deeply.** Don't face complex issues head-on; first understand simple ideas deeply. Clear the clutter and expose what is really important. Be brutally honest about what you know and don't know. Then see what's missing, identify the gaps, and fill them in. Let go of bias, prejudice, and preconceived notions. There are degrees to understanding (it's not just a yes-or-no proposition) and you can always heighten yours. Rock-solid understanding is the foundation for success.
- **Make Mistakes.** Fail to succeed. Intentionally get it wrong to inevitably get it even more right. Mistakes are great teachers — they highlight unforeseen opportunities and holes in your understanding. They also show you which way to turn next, and they ignite your imagination.
- **Raise Questions.** Constantly create questions to clarify and extend your understanding. What's the real question? Working on the wrong questions can waste a lifetime. Ideas are in the air — the right questions will bring them out and help you see connections that otherwise would have been invisible.
- **Follow the Flow of Ideas.** Look back to see where ideas came from and then look ahead to discover where those ideas may lead. A new idea is a beginning, not an end. Ideas are rare— milk them. Following the consequences of small ideas can result in big payoffs. These are the four basic building blocks for effective thinking. The fifth is Change.
- **Change.** The unchanging element is change— by mastering the first four elements, you can change the way you think and learn. You can always improve, grow, and extract more out of your education, yourself, and the way you live your life. Change is the universal constant that allows you to get the most out of living and learning.

6. Step 6-Collect As Many mental models as Possible from diverse domains and academic disciplines That I think is suitable for my situation or Information provided by the Text, Book, Speech etc. Research a broad range of industries to identify mental models that can be integrated and Most Suitable into area of work or focus. In identifying the Great Mental Models we have to look for elementary principles, the ideas from multiple disciplines that form a time tested foundation, these mental models would be from Elementary Mental Models to most Advanced Mental Models. It may seem counterintuitive, to work on developing knowledge that is available to everyone, but the universe works in the same way no matter where you are in it or how you think the universe should be working. What you need is to understand the principles, so that when the details change you are still able to identify what is really going on. Listen and Follow Every Book on Each Mental models.

A. General Mental Models For Thinking.

I. The Great Mental Models Volume 1 By Fs Blog.

- The Map is Not The Territory.
- Circle of Competence.
- The first Principles Thinking.
- Though Experiment.
- Second Order Thinking.
- Probabilistic Thinking.
- Inversion.
- Occam's Razor.
- Hanlon's Razor.
- Supporting Ideas.
- Falsifiability.
- Necessity and Sufficiency.
- Causation vs Correlation.

II. The Great Mental Models Volume 2 By Fs Blog.

- Physics.
 - Relativity.
 - Reciprocity.
 - Thermodynamics.
 - Inertia.

- Friction and Viscosity.
- Velocity
- Leverage.
- Chemistry.
 - Activation Energy.
 - Catalysts.
 - Alloying,
- Biology.
 - Evolution Part One: Natural Selection and Extinction.
 - Evolution Part two: Adaptation Rate and The Red Queen Effect.
 - Supporting Idea: Competition.
 - Ecosystem.
 - Niche.
 - Self Preservation.
 - Replication.
 - Cooperation.
 - Supporting Idea: Dunbar's Number.
 - Hierarchical Organisation.
 - Incentives.
 - Tendency to Minimize energy Output.

III. The Great Mental Models Volume 3 By Fs Blog.

- Systems.
 - Feedback Loops.
 - Equilibrium.
 - Bottlenecks.
 - Scale.
 - Margin of Safety.
 - Churn.
 - Algorithms.
 - Supporting Idea: Complex Adaptive Systems.
 - Critical mass.

- Emergence.
- Supporting Idea: Chaos Dynamics.
- Irreducibility.
- Law of Diminishing Returns.
- Mathematics.
 - Supporting Idea: Distribution.
 - Compounding.
 - Supporting Idea; Network Effect.
 - Sampling.
 - Randomness.
 - Supporting idea: Pareto Principle.
 - Regression to the mean.
 - Multiplying by ZERO.
 - Equivalence.
 - Supporting idea: order of Magnitude.
 - Surface Area.
 - Global and local Maxima.

IV. The Great Mental Models By Tommy Tedford.

- First Principles Mental model.
- Classical Condition.
- Cognitive Biases.
- Circle Of Competence Mental Model.
- Eisenhower Matrix.

V. 100 Mental Models- Be Rational by Wisdom Theory.

- Philosophy.
 - Meaning Of Life.
 - Stoicism.
 - Cave of plato.
 - Golden Rule.
 - Constructivism.

- **Maths.**
 - Algebra.
 - Permutations and combinations.
 - Algorithms.
 - Scale.
 - Compound interest.
 - Inflection point.

- **Physics.**
 - Scientific Method.
 - Breakpoint.
 - Critical mass.
 - Reciprocity.
 - Velocity.
 - Relativity.
 - Leverage.
 - Newton's Laws of Motion.
 - Chaos Theory.
 - Complex Adaptive Systems.
 - Activation Energy.
 - Laws of Thermodynamics.
 - Heisenberg Uncertainty Principle.

- **Statistics.**
 - Probabilistic thinking.
 - Bayes Theorem.
 - Power Law.
 - Regression to the Mean.
 - Game Theory.
 - Correlation and Causation.
 - Standard Deviation.
 - Law of large numbers.
 - Inversion.
 - Fragility / Robustness / Antifragility.
 - Black Swan.

- **Engineering.**
 - **Redundancy: Margin of safety.**
 - **Backup system model.**
 - **Breakpoint.**
 - **Quality control.**
 - **Feedback loops.**

- **Chemistry.**
 - **Atoms, Molecules, and Ions.**
 - **The Chemical Bond.**
 - **Molecular Shape and Geometry.**
 - **The Kinetic Theory.**
 - **The Chemical Reaction.**
 - **Autocatalyst.**

7. **Step 7-Getting familiar:** At this starting point, users decide if they can use an existing mental model (maybe one used for another similar product) or if they need to start from scratch. The existing mental model may be void of useful knowledge or worse, contain the wrong knowledge. The core components missing at this stage include an understanding of the language the product uses and the actionable steps needed to complete core tasks.
8. **Step 8-Apply simple criteria to which mental models you use.** When selecting mental models to include into your own latticework, consider whether they support you to better understand yourself and/or the world around you, so you might better effective and impactful action. Also Mental models do two things: they help you assess how things work and they help you make better decisions. Ask some Questions:
 - I. How long has this model been around? As a general rule, mental models which have been around for a long time (such as Occam's razor) will have been subjected to a great deal of scrutiny. Time is an excellent curator, trimming away inefficient ideas. A mental model which is new may not be particularly refined or versatile. Many of our mental models originate from Ancient Greece and Rome, meaning they have to be functional to have survived this long.
 - II. Is it a representation of reality? In other words, does it reflect the real world? Or is it based on abstractions?
 - III. Does this model apply to multiple areas? The more elastic a model is, the more valuable it is to learn about. (Of course, be careful not to apply the model where it doesn't belong. Mind Feynman: "You must not fool yourself, and you're the easiest person to fool.")
 - IV. How did this model originate? Many mental models arise from scientific or mathematical concepts. The more fundamental the domain, the more likely the model is to be true and lasting.
 - V. Is it based on first principles? A first principle is a foundational concept which cannot be deduced from any other concept and must be known.
 - VI. Does it require infinite regress? Infinite regress refers to something which is justified by principles, which themselves require justification by other principles. A model based on infinite regress is likely to

required extensive knowledge of a particular topic, and have minimal real-world application.

9. **Step 9- *Becoming proficient*:** Users begin to understand the language of the situation or text, especially if this language uses technical or unfamiliar vernacular. Understanding terminology and use of product language is one of the first building blocks that form the foundation of the model. This is also when users start to understand the step-by-step procedures required to perform basic operations to get some desired outcome. Here, they are usually learning the bread-and-butter operations of the product so they can receive enough value to motivate them to keep using it. Later, they will be able to build on this knowledge.
10. **Step 10- Make connections between mental models.** We need to know full context and not isolated facts. Rather than holding siloed mental models in your mind, consider how they interact, connect and complement one another.
11. **Step 11-Think, what light the mental model can bring on the situation, idea, text , speech etc.** Do I see the situation, idea, text, speech etc, in the new way? What new way can I see the situation? Does This Makes easier to make a decision in my life?
12. **Step 12- Think very carefully, if each chosen Mental model applicable to situation, idea, text, speech etc.**
13. **Step 13-Use the Chosen Mental Models tool.** The canvas, below, will help you to identify high-value areas where new mental models can make the biggest impact on your work and life. It also provides a simple framework to begin to embed using your chosen models.
14. **Step 14-*Mastering*:** Users build on the core step-by-step tasks they already know, expanding their knowledge to more complex or niche capabilities. If they make it this far they most likely have an accurate understanding of most or all of the language the product uses.
15. **Step 15-Regularly reassess their priorities without fear of changing them.** They don't fall prey to inertia.
16. **Step 16-Be biased toward taking action—not lazily deferring.** If they encounter a mental model they value, they make sure they use it.
17. **Step 17-Be always looking to prove yourselves wrong.** Ego should not get in the way of mental models.

18. Step 18-Accepting that all models are wrong in certain instances is not a license to ignore the facts. As a society, we should search for better answers, look for evidence, and strive to increase the accuracy of our knowledge.

- I. That's not to say all lenses (or models) apply to all problems. They don't. And it's not to say that having more lenses (or models) will be a advantage in all problems. It won't. This is why learning and applying the Great Mental Models is a process that takes some work. But the truth is, most problems are multidimensional, and thus having more lenses often offers significant help with the problems we are facing.**
- II. The more you use them, the more you will be able to build the knowledge of indicators that can trigger the use of the most appropriate model. Using and failing, as long as you acknowledge, reflect, and learn from it, is also how you build your repertoire. You need to be deliberate about choosing the models you will use in a situation. As you use them, a great practice is to record and reflect. That way you can get better at both choosing models and applying them. Take the time to notice how you applied them, what the process was like, and what the results were. Over time you will develop your knowledge of which situations are best tackled through which models. Don't give up on a model if it doesn't help you right away. Learn more about it, and try to figure out exactly why it didn't work. It may be that you have to improve your understanding. Or there were aspects of the situation that you did not consider. Or that your focus was on the wrong variable.**

- 19. Step 19-After all Analysis, decide what models are the most suitable after all to apply.**
- 20. Step 20-Apply The Mental Model in Real Life or Reality, and let the world do the work for You.**

Step 142 - Interdisciplinary Thinking

1. **Step 1 Define Interdisciplinary Thinking.** "Interdisciplinary" comes from the process of merging and integrating different disciplines together with their methodologies and presumptions. It includes crossing the formal borders between sciences and combining their methods in favor of a common purpose. "Methodologies and assumptions belonging to different disciplines are connected and modified in order to adapt to the needs of the research, creating new tools which allow for the investigation of difficult subjects that surpass the possibilities of a single discipline. In the field of architecture, for instance, complex topics such as SDGs, urban transitional, sustainability, and design imply various approaches that combine chemistry, drafting for design, engineering design, fundamentals of physics, architectural illumination and electrical systems. Interdisciplinarity may be regarded as a step up from multidisciplinary. Interdisciplinary studies focus on addressing specific 'real world' system problems and, as a result, the research process forces participants (from a variety of unrelated disciplines) to cross boundaries to create new knowledge. Essentially the major difference from multidisciplinary lies in the *level of integration and cooperation* as these projects seek to bridge disciplinary viewpoints and potentially enable the examination of existing accumulated knowledge from the perspective of a neighboring discipline. Huutoniemi *et al.* provide a relatively comprehensive typology of interdisciplinarity along with specific indicators for research teams to grasp on to. At the same time, Schmidt outlines the importance of a basic literacy in the philosophy of science related to doing such work as well as the kinds of interdisciplinarity. The necessity of bridging disciplinary viewpoints generally (as with transdisciplinarity) stems from the need to address complex "problems that involve an interface of human and natural systems" and, as such, the integration of natural and social scientists is standard practice for interdisciplinary research. This approach involves bringing people and ideas together from different disciplines to jointly frame a problem, agree on a methodological approach, and analyze data. Thus interdisciplinary research requires a much more collaborative approach to problem formulation and methodological development than multidisciplinary research. Interdisciplinary

working starts to take a new form, integrating knowledge and methods from different disciplines and synthesising into a new whole. It's like a stew: the original ingredients are still partly distinguishable, but the overall is a blended pot of mixed flavours. Let's review the process that Pinker has laid out, one that we might think about emulating as we examine the causes of complex phenomena in human systems:

- I. We observe an interesting phenomenon in need of explanation, one we feel capable of exploring.
- II. We propose and examine competing hypotheses that would explain the phenomena (set up in a falsifiable way, in harmony with the divide between science and pseudoscience laid out for us by the great Karl Popper).
- III. We examine a cross-section of: Empirical data relating to the phenomena; sensible qualitative inference (from multiple fields/disciplines, the more fundamental the better), and finally; "Demonstrable" aspects of nature we are nearly certain about, arising from controlled experiment or other rigorous sources of knowledge ranging from engineering to biology to cognitive neuroscience.

IV. Listen and Apply The Following Books:

- **How we can Assess the Level of Interdisciplinarity and Transdisciplinarity of Academic Institutions? By Mahmood Ramezanzade**
- **Detection of Distributed Denial of Service (DDoS) Attacks in IOT Based Monitoring System of Banking Sector Using Machine Learning Models By Muhsmmsf Shafiq**

2. Step 2-Do Work Required to Have an Opinion on Any Topic and Anything.

- I. Most people go through life not really getting any smarter. Why? They simply won't do the work required. It's easy to come home, sit on the couch, watch TV, and zone out until bedtime rolls around. But that's not going to help you get smarter.
- II. You can acquire knowledge if you want it. In fact, there is a simple formula, which if followed is almost certain to make you smarter over time. Simple but not easy. It involves a lot of hard work. "The best thing a human being can do is to help another human being know more."
- III. How to Get Smarter Read. A lot. Warren Buffett says, "I just sit in my office and read all day." What does that mean? He estimates that he spends 80% of his working day reading and thinking. When asked how to get smarter, Buffett once held up stacks of paper and said, "Read 500 pages like this every week. That's how knowledge builds up, like compound interest." All of us can build our knowledge, but most of us won't put in the effort. "Go to bed smarter than when you woke up."
- IV. Knowledge accumulation as an acquired, rather than natural, genius. And he'd give all the credit to the studying;.
- V. The first thing they always do is tell you what they think. When someone has an opinion about everything, they want to share it with you. They often tout stats and research as if they had an imaginary checklist of facts they need to be able to rattle off to establish themselves as an expert in a field they actually know very little about. Because they have an opinion on everything, they are quick to judge others – for their lack of opinions, for their lack of knowledge, for their lack of outrage ... the list goes on.
- VI. People who have opinions about everything barf so much noise that it's hard to find the signal. Your brain has to work overtime to figure out if they did the work to come up with their opinions themselves or if they're simply regurgitating some op-ed in a newspaper. Over time, opinionated people also end up in their own prisons and they try to take you with them.
- VII. The problem comes from how we see the world. Our opinions are often rooted in how we think the world should work, according to our morals, values, and principles. If we see the world through the lens of our opinions, much of what happens will not agree with us. This is feedback, and how we respond to this feedback is key.

VIII. While we all hold an opinion on almost everything. Have I do the work required to have an opinion on any Subject? Never allow myself to have an opinion on anything that I don't know the other side's argument better than they do. The work required to have an opinion is very hard part, have I avoid it?

- I have to do the reading.
- I have to do Thinking and mental model.
- I have to talk to competent people and understand their arguments.
- I have to think about the key variables and how they interact over time.
- I have to listen and chase down arguments that run counter to your views.
- I have to think about how you might be fooling yourself.
- I have to see the issue from multiple perspectives.
- I have to think.
- I need to become your most intelligent critic and have the intellectual honesty to kill some of your best-loved ideas.

IX. If that sounds like a lot of work, just say, "I don't have an opinion on that; why don't you tell me how you got to have such a firm one? It sounds like I could learn something."

X. We all are learning, modifying, or destroying ideas all the time. Rapid destruction of your ideas when the time is right is one of the most valuable qualities you can acquire. You must force yourself to consider arguments on the other side. As Rabbi Moses ben Maimon (1135–1204), commonly known as Maimonides, said: "Teach thy tongue to say I do not know, and thou shalt progress."

XI. Doing the work required to hold an opinion means you can argue against yourself better than others can. Only then can you say, "I can hold this view because I can't find anyone else who can argue better against my view." Great thinkers, like Charles Darwin, did the work. And it's one of the biggest reasons he's buried at Westminster Abbey.

XII. Doing the work counteracts our natural desire to seek out only information that confirms what we believe we know. When Darwin encountered opinions or facts that ran contrary to his ideas, he endeavored not only to listen but also not to rest until he could either argue better than his challengers or understand how the fact fit. Darwin did the work. It's wasn't easy, but that's the point.

XIII. The difference between the people who do the work and the people who just reel off memorized opinions is huge. When you do the work, you can answer the next question. You know when to follow the rules and when they'll get you in trouble. When I did my postgraduate I was surrounded by people who could answer the test questions. They got good grades — actually, they got *great* grades but an odd thing happened after school: a lot of those people couldn't apply their knowledge to problems they hadn't seen before. They were chauffeurs — they knew the memorized answer. They couldn't answer the next question. We're all chauffeurs in some aspects of our lives. This is why understanding your circle of competence is so critical to living a rational life.

- Circle of Competence:

- **Circle Of Competence**-Understanding my Circle of Competence helps to avoid problems, identify opportunities for improvement and learn from Others. Circle of Competence is simple: Each of us, through experience or study, has built up useful knowledge on certain areas of the world. Some areas are understood by most of us, while some areas require a lot more specialty to evaluate. For example, most of us have a basic understanding of the economics of a restaurant: You rent or buy space, spend money to outfit the place and then hire employees to seat, serve, cook, and clean. (And, if you don't want to do it yourself, manage.) From there, it's a matter of generating enough traffic and setting the appropriate prices to generate a profit on the food and drinks you serve —after all of your operating expenses have been paid. Though the cuisine, atmosphere, and price points will vary by restaurant, they all have to follow the same economic formula. That basic knowledge, along with some understanding of accounting and a little bit of study, would enable one to evaluate and invest in any number of restaurants and restaurant chains, public or private. It's not all that complicated. Far more important is to honestly define what we do know and stick to those areas. Our circle of competence can be widened, but only slowly and over time. Mistakes are most often made when straying from this discipline. Where should we devote our limited time in life, to achieve the most success? So, the simple takeaway here is clear. If you want to improve your odds of success in life and business, then define the perimeter of your circle of competence, and operate inside. Over time,

work to expand that circle but never fool yourself about where it stands today, and never be afraid to say “I don’t know.”

- The Two Types of Knowledge: The Max Planck and Chauffeur Test: How to distinguish between the two types of knowledge: real knowledge and pretend knowledge.
 - The first type of knowledge is real. It can’t be bought. It can’t be copied. If you want real knowledge you need to earn it. One is Planck knowledge, the people who really know. They’ve paid the dues, they have the aptitude. You are going to have the problem in your life of getting the responsibility into the people with the Planck knowledge and away from the people with the chauffeur knowledge. Real knowledge comes when people do the work. The problem is that it’s difficult to separate the two. This is the Batesian Mimicry problem. One way to tease out the difference between Planck and chauffeur knowledge is to ask them why.
 - The second type of knowledge is copied. On the surface you know the answer but you lack the understanding to show your work. Then we’ve got chauffeur knowledge. They’ve learned the talk. They may have a big head of hair, they may have fine temper in the voice, they’ll make a hell of an impression. But in the end, all they have is chauffeur knowledge. I think I’ve just described practically every politician in the United States. We have the people who don’t do the work — they pretend. While they’ve learned to put on a good show, they lack understanding. They can’t answer questions that don’t rely on memorization. They can’t explain things without using jargon or vague terms. They have no idea how things interact. They can’t predict the consequences. The problem is that it’s difficult to separate the two. This is the Batesian Mimicry problem. One way to tease out the difference between Planck and chauffeur knowledge is to ask them why.
 - How To Distinguish Real Knowledge and Fake Knowledge. With journalists, it is more difficult. Some have acquired true knowledge. Often they are veteran reporters who have specialized for years in a clearly defined area. They make a serious effort to understand the

complexity of a subject and to communicate it. They tend to write long articles that highlight a variety of cases and exceptions. The majority of journalists, however, fall into the category of chauffeur. They conjure up articles off the tops of their heads or, rather, from Google searches. Their texts are one-sided, short, and— often as compensation for their patchy knowledge. The same superficiality is present in business. The larger a company, the more the CEO is expected to possess “star quality.” Dedication, solemnity, and reliability are undervalued, at least at the top. Too often shareholders and business journalists seem to believe that showmanship will deliver better results, which is obviously not the case. One way to guard against this is to understand your circle of competence. Dobelli concludes with some advice worth taking to heart. Be on the lookout for chauffeur knowledge. Do not confuse the company spokesperson, the ringmaster, the newscaster, the schmoozer, the verbiage vendor, or the cliché generator with those who possess true knowledge. How do you recognize the difference? There is a clear indicator: True experts recognize the limits of what they know and what they do not know. If they find themselves outside their circle of competence, they keep quiet or simply say, “I don’t know.” This they utter unapologetically, even with a certain pride. From chauffeurs, we hear every line except this.

- Batesian Mimicry Problem. Batesian Mimicry: Why Copycats Are Successful. Mimic and the Real Thing:
 - “There’s two kinds of snakes you come across. There’s the Texas Coral Snake, and the Mexican Milk Snake, and they both look exactly alike. The Texas Coral Snake is dangerous, it’s venomous, it can kill you in a minute. The Mexican Milk Snake can’t do anything to you; it’s an impostor.”How is it that these two look alike? It’s due to a phenomenon called Batesian Mimicry.
 - In the 1850s, the naturalist Henry Walter Bates found a certain set of butterflies who were clearly *not* of the same species but whose wings looked almost the same to the naked eye. After thinking it over, Bates eventually figured out what was going on: While the butterflies which were toxic to potential predators (the “models”) were able to operate freely and relatively unmolested, there had also developed a “mimic” population of butterflies which wasn’t toxic at all, yet still went untouched! In fact, biologists eventually figured out that the more toxic and dangerous the “model” was and the more frequently they appeared in the local population, the easier it was for its “mimics” to get by! Predators simply wouldn’t take the risk of mixing up the two. If there aren’t as many “models” around or they aren’t that dangerous, the mimics have a harder time.
 - This is a wonderful model, and in the practical world we live in, a similar phenomenon abounds: Copycats or “pretenders to the throne” are often very effective, very convincing “mimics” of the true champions. They dress the part, they talk the talk, and they know what buttons to push. But in the end, they are merely chauffeurs. We see a very Batesian effect at work: The more impressive the “model,” the more effective its mimics can be in convincing people they too are impressive, and in all the same ways. But for every Warren Buffett (just one by our count), there has been many “future” Warren Buffett’s. For every Steve Jobs, there have been many “next” Steve Jobs’. In fact, sometimes even just *appearances* can be quite convincing: now-disgraced Theranos founder Elizabeth Holmes was very fond of wearing a very Steve Jobsian black turtleneck outfit. Because they can be very convincing, we must be wise enough to watch out for Batesian mimicry

— even in ourselves. This brings up an interesting, at times paradoxical, question: Who can best tell the difference between a Coral Snake and its Mimics? The Coral Snake itself. The real thing knows a fake. It's worth taking the time to work on learning all the big ideas you can find, not just the ones you want to learn. In that search, you'll find a host of big winners you didn't even know existed.

XIV. The ability to destroy your ideas rapidly instead of slowly when the occasion is right is one of the most valuable things. You have to work hard on it. Ask yourself what are the arguments on the other side. It's bad to have an opinion you're proud of if you can't state the arguments for the other side better than your opponents. This is a great mental discipline.

XV. Doing the work means you can't make up your mind with a high degree of confidence right away. Doing the work forces you to challenge your beliefs because you have to argue from both sides. You become the somewhat impartial judge. What's on trial is your opinion. If you want to work with the world rather than against it, one of the major leverage points you can put effort into is how to distinguish between the people who've done the work and those who haven't. The ones who have will pass the Batesian Mimicry Test.

XVI. As Per Kobe Bryant statement: Trivial things should not be taken your attention. The attentions should be focused on things that is very important. Anything outside of the most important things in life, you should not have time for. You Should love the challenge in life, and always be curious, if you can be at the top , as these greats in that area. Always focus on one thing and not multiple things, this gives an edge and advantage over other people, who focusing on multiple things in life. The World Becomes a library to you, to be better at your craft.: Everything you see whether TV show I saw, Books, Journals, I read, whether discussion, debate I listen, people I talk to. Everything was done to try to learn to become better at the craft your focusing. When you have this point of you, then the world becomes your library to help you to become better at the craft.

XVII. Have the best work ethic on daily basis. This is everyday process, and try to figure it out, the strengths and weaknesses of my position and opposing person position.

XVIII. Always look at the reality of the situation, and do not let the emotion cloud the situation and the execution. Always be in the present and the moment.

XIX. We read a lot. I don't know anyone who's wise who doesn't read a lot. But that's not enough: You have to have a temperament to grab ideas and do sensible things. Most people don't grab the right ideas or don't know what to do with them.

XX. Another way to get smarter, outside of reading, is to surround yourself with people who are not afraid to challenge your ideas. "Develop into a lifelong self-learner through voracious reading; cultivate curiosity and strive to become a little wiser every day."

3. Step 3- Slow Down

I. Do Not Rush Thinking Process, and Do it Very Slow.

II. Do Not Rush Any Task I will do At Any Time.

III. Listen and Apply Book “The Slow Fix Solve Problems, Work Smarter, and Live Better in a World Addicted to Speed”

IV. Listen and Apply Book *In Praise Of Slowness Challenging the Cult of Speed BY Carl Honore.

- We live in a world scarce of understanding and abundant with information. We complain that we never have any free time yet we seek distraction. If work can't distract us, we distract ourselves. We crave perpetual stimulation and motion. We're so busy that our free time comes in 20 second bursts, just long enough for us to read the gist and assume we understand. If we are to synthesize learning and understanding we need time to think.
- The modern storm of bits and stimulation, relents only when we sleep. (And then only if we remember to turn off the phone.) Lost in all of this is the art of stillness. We live in a world with more information than ever and yet we understand less. We have come into the belief that the simple act of reading confers understanding. Worse, most of our reading is elementary reading, or skimming — a far cry from syntopical reading, which seems more fertile for the mind willing to do the work.
- But that's just it. We don't want, or can't find the time, to do the work that's required to hold an opinion. It's much easier to simply read the opinions of another and let them think for us.
- Understanding comes from focusing, chewing, and relentlessly ragging on a problem. It comes with false starts, dead ends, and frustration. Thinking requires time and space. It's slow. It means saying I don't know. In short, thinking is everything the modern workplace is designed to eradicate.
- We're expected to have an opinion about everything and yet our time to think is near zero. We hold more opinions than ever but have less understanding. We don't even understand ourselves. How could it be otherwise?
- As Milan Kundera wrote in his 1996 novella Slowness, “When things happen too fast, nobody can be certain about anything, about anything at all, not even about himself. “In our fast-moving modern world, it always

seems that the time-train is pulling out of the station just as we reach the platform. No matter how fast we go, no matter how cleverly we schedule, there are never enough hours in the day.”

- Carl Honore, wrote a book, In Praise of Slowness: Challenging the Cult of Speed, to explore why we’re always in such a rush, what if anything is the cure for time-sickness, and whether it’s desirable to slow down. The book is not an all-out declaration of war against speed. Speed has helped to remake our world in ways that are wonderful and liberating. Who wants to live without the Internet or jet travel? The problem is that our love of speed, our obsession with doing more and more in less and less time, has gone too far; it has turned into an addiction, a kind of idolatry. Even when speed starts to backfire, we invoke the go-faster gospel.
- When we rush, we skim the surface, and fail to make real connections with the world or other people.” Moreover we don’t make connections with ideas. We don’t synthesize. We don’t test theories over time. We don’t play with ideas.
- The implications on thinking are fascinating. We are all fast-thinkers now. We have forgotten how to look forward to things, and how to enjoy the moment when they arrive. Restaurants report that hurried diners increasingly pay the bill and order a taxi while eating dessert. Many fans leave sporting events early, no matter how close the score is, simply to steal a march on the traffic. Then there is the curse of multi-tasking. Doing two things at once seems so clever, so efficient, so modern. And yet what it often means is doing two things not very well. Like many people, I read the paper while watching TV— and find that I get less out of both. In this media-drenched, data-rich, channel-surfing, computer-gaming age, we have lost the art of doing nothing, of shutting out the background noise and distractions, of slowing down and simply being alone with our thoughts. Boredom— the word itself hardly existed 150 years ago— is a modern invention. Remove all stimulation, and we fidget, panic and look for something, anything, to do to make use of the time. When did you last see someone just gazing out the window on a train? Everyone is too busy reading the paper, playing video games, listening to iPods, working on the laptop, yammering into mobile phones. Instead of thinking deeply, or letting an idea simmer in the back of the mind, our instinct now is to reach for the

nearest sound bite. In modern warfare, correspondents in the field and pundits in the studio spew out instant analyses of events as they occur. Often their insights turn out to be wrong. But that hardly matters nowadays: in the land of speed, the man with the instant response is king. With satellite feeds and twenty-four-hour news channels, the electronic media is dominated by what one French sociologist dubbed “le fast thinker”— a person who can, without skipping a beat, summon up a glib answer to any question.

- Fast eats time. One consequence of fast is that we make poor decision after poor decision. Those decisions don’t go away never to be seen again. It’s not like we make a bad decision and we’re done with it. No, the consequences are much worse. Poor decisions eat time. They come back to haunt you. They create issue after issue. They feed into the perpetual motion machine of busyness. And in a culture where people wear busyness as a badge of honor bad decisions actually lead us to think that we’re doing more.

V. Do The Tasks Slowly, and Step By Step.

VI. The Art of Slowing down and Do Not Rush Anything.

- The Art of Stillness is a persuasively argued case for the pleasures of slowing down and being in one place. Today we’re going faster and faster in search of contentment and meaning. This is largely a recipe for ensuring we will never be happy. We have the sense, too often, of running at top speed and never being able to catch up.
- Too many of us see going nowhere as turning away from something rather than turning towards something.
- Going nowhere isn’t about turning your back on the world; it’s about stepping away now and then so that you can see the world more clearly and love it more deeply. “There is nothing either good or bad, but thinking makes it so.”
- The idea behind choosing to sit still long enough to learn about yourself is simple and has been around for ages. Marcus Aurelius and Epictetus reminded us many millennia ago that it’s how we respond to our experiences, not the experiences themselves, which shape us.

- The greatest weapon against stress is our ability to choose one thought over another. Part of making better decisions is making time to think. Something that few of us are able to do.
- “Our creations come not when we’re out in the world, gathering impressions, but when we’re sitting still, turning those impressions into sentences.

4. Step 4- Do not Multitask.

- I. Of course you can do more than one thing at once. The catch is you can’t do more more than one thing at once that requires concentration. You can walk and chew gum, but you can’t write an email and a report at the same time. When you’re doing two things at once that are cognitively demanding, what you’re really doing is switching back and forth very quickly from one task to another.
- II. There is a mental cost—called a switching cost—to all of this multitasking. But that’s not all it makes deep thinking impossible.
- III. I think people that multitask pay a huge price. They think they’re being extra productive, and I think they’re (out of their mind). I use the metaphor of the one-legged man in the ass-kicking contest. I think when you multi-task so much, you don’t have time to think about anything deeply. You’re giving the world an advantage you shouldn’t do. Practically everybody is drifting into that mistake. Concentrating hard on something that is important is. I can’t succeed at all without doing it. I did not succeed in life by intelligence. I succeeded because I have a long attention span.
- IV. It sounds counter-intuitive but if you want to increase discretionary time and reduce stress you need to schedule time to think. The tiny fragments of time many of us find ourselves with have a negative effect on our ability to think deeply about a problem. Furthermore they impede our ability to learn — we stay at a surface level and never move into a deep understanding. Deresiewicz warns: “You simply cannot (think) in bursts of 20 seconds at a time, constantly interrupted by Facebook messages or Twitter tweets, or fiddling with your iPod, or watching something on YouTube.”
- V. The opposite approach is to focus on a problem or subject and try to achieve a deep fluency. How many of us, however, have time? We don’t do the work required to have an opinion. Instead we operate with surface knowledge. We tackle problems with the first thought that comes to mind. Because we make a

poor initial decision, we spend countless hours attempting to correct it. No wonder we have no time to think. We're not heeding the advice of Joseph Tussman and letting the world do the work for us.

VI. Listen and Apply The Following Books:

- **The Multitasking Mind By Dario Saliveci**

5. Step 5-What is Thinking/

I. Thinking Rate

- **You can't force yourself to think faster. If you try, you're likely to end up making much worse decisions. Here's how to improve the actual quality of your decisions instead of chasing hacks to speed them up.**
- **When the product of your job is your decisions, you might find yourself wanting to be able to make more decisions more quickly so you can be more productive overall.**
- **Chasing speed is a flawed approach. Because decisions—at least good ones—don't come out of thin air. They're supported by a lot of thinking.**

II. Beyond The Hurry Culture

- **Everyone is trying to work faster at all times, and they pressure everyone around them to work faster, too.**
- **All of these things increase pressure in the work environment and repeatedly reinforce the “hurry up!” message. They make managers feel like they're moving things along faster. That way if work isn't getting done, it's not their fault. But, DeMarco writes, they don't lead to meaningful changes in behavior that make the whole organization more productive. Speeding up often results in poor decisions that create future problems.**
- **The reason more pressure doesn't mean better productivity is that the rate at which we think is fixed. We can't force ourselves to start making faster decisions right now just because we're faced with an unrealistic deadline. DeMarco writes, “*Think rate is fixed. No matter what you do, no matter how hard you try, you can't pick up the pace of thinking.*”**

III. Elements of Effective Thinking

- **Understand Deeply.** Don't face complex issues head-on; first understand simple ideas deeply. Clear the clutter and expose what is really important. Be brutally honest about what you know and don't know. Then see what's missing, identify the gaps, and fill them in. Let go of bias, prejudice, and preconceived notions. There are degrees to understanding (it's not just a yes-or-no proposition) and you can always heighten yours. Rock-solid understanding is the foundation for success.
- **Make Mistakes.** Fail to succeed. Intentionally get it wrong to inevitably get it even more right. Mistakes are great teachers — they highlight unforeseen opportunities and holes in your understanding. They also show you which way to turn next, and they ignite your imagination.
- **Raise Questions.** Constantly create questions to clarify and extend your understanding. What's the real question? Working on the wrong questions can waste a lifetime. Ideas are in the air — the right questions will bring them out and help you see connections that otherwise would have been invisible.
- **Follow the Flow of Ideas.** Look back to see where ideas came from and then look ahead to discover where those ideas may lead. A new idea is a beginning, not an end. Ideas are rare— milk them. Following the consequences of small ideas can result in big payoffs. These are the four basic building blocks for effective thinking. The fifth is Change.
- **Change.** The unchanging element is change— by mastering the first four elements, you can change the way you think and learn. You can always improve, grow, and extract more out of your education, yourself, and the way you live your life. Change is the universal constant that allows you to get the most out of living and learning.

6. Step 6-Collect As Many mental models as Possible from diverse domains and academic disciplines That I think is suitable for my situation or Information provided by the Text, Book, Speech etc. Research a broad range of industries to identify mental models that can be integrated and Most Suitable into area of work or focus. In identifying the Great Mental Models we have to look for elementary principles, the ideas from multiple disciplines that form a time tested foundation, these mental models would be from Elementary Mental Models to most Advanced Mental Models. It may seem counterintuitive, to work on developing knowledge that is available to everyone, but the universe works in the same way no matter where you are in it or how you think the universe should be working. What you need is to understand the principles, so that when the details change you are still able to identify what is really going on. Listen and Follow Every Book on Each Mental models.

A. General Mental Models For Thinking.

I. The Great Mental Models Volume 1 By Fs Blog.

- The Map is Not The Territory.
- Circle of Competence.
- The first Principles Thinking.
- Though Experiment.
- Second Order Thinking.
- Probabilistic Thinking.
- Inversion.
- Occam's Razor.
- Hanlon's Razor.
- Supporting Ideas.
- Falsifiability.
- Necessity and Sufficiency.
- Causation vs Correlation.

II. The Great Mental Models Volume 2 By Fs Blog.

- Physics.
 - Relativity.
 - Reciprocity.
 - Thermodynamics.
 - Inertia.

- Friction and Viscosity.
- Velocity
- Leverage.

- Chemistry.
 - Activation Energy.
 - Catalysts.
 - Alloying,

- Biology.
 - Evolution Part One: Natural Selection and Extinction.
 - Evolution Part two: Adaptation Rate and The Red Queen Effect.
 - Supporting Idea: Competition.
 - Ecosystem.
 - Niche.
 - Self Preservation.
 - Replication.
 - Cooperation.
 - Supporting Idea: Dunbar's Number.
 - Hierarchical Organisation.
 - Incentives.
 - Tendency to Minimize energy Output.

III. The Great Mental Models Volume 3 By Fs Blog.

- Systems.
 - Feedback Loops.
 - Equilibrium.
 - Bottlenecks.
 - Scale.
 - Margin of Safety.
 - Churn.
 - Algorithms.
 - Supporting Idea: Complex Adaptive Systems.
 - Critical mass.

- Emergence.
- Supporting Idea: Chaos Dynamics.
- Irreducibility.
- Law of Diminishing Returns.
- Mathematics.
 - Supporting Idea: Distribution.
 - Compounding.
 - Supporting Idea; Network Effect.
 - Sampling.
 - Randomness.
 - Supporting idea: Pareto Principle.
 - Regression to the mean.
 - Multiplying by ZERO.
 - Equivalence.
 - Supporting idea: order of Magnitude.
 - Surface Area.
 - Global and local Maxima.

7. **Step 7-Getting familiar:** At this starting point, users decide if they can use an existing mental model (maybe one used for another similar product) or if they need to start from scratch. The existing mental model may be void of useful knowledge or worse, contain the wrong knowledge. The core components missing at this stage include an understanding of the language the product uses and the actionable steps needed to complete core tasks.
8. **Step 8-Apply simple criteria to which mental models you use.** When selecting mental models to include into your own latticework, consider whether they support you to better understand yourself and/or the world around you, so you might better effective and impactful action. Also Mental models do two things: they help you assess how things work and they help you make better decisions. Ask some Questions:
 - I. How long has this model been around? As a general rule, mental models which have been around for a long time (such as Occam's razor) will have been subjected to a great deal of scrutiny. Time is an excellent curator, trimming away inefficient ideas. A mental model which is new may not be particularly refined or versatile. Many of our mental models originate from Ancient Greece and Rome, meaning they have to be functional to have survived this long.
 - II. Is it a representation of reality? In other words, does it reflect the real world? Or is it based on abstractions?
 - III. Does this model apply to multiple areas? The more elastic a model is, the more valuable it is to learn about. (Of course, be careful not to apply the model where it doesn't belong. Mind Feynman: "You must not fool yourself, and you're the easiest person to fool.")
 - IV. How did this model originate? Many mental models arise from scientific or mathematical concepts. The more fundamental the domain, the more likely the model is to be true and lasting.
 - V. Is it based on first principles? A first principle is a foundational concept which cannot be deduced from any other concept and must be known.
 - VI. Does it require infinite regress? Infinite regress refers to something which is justified by principles, which themselves require justification by other principles. A model based on infinite regress is likely to

required extensive knowledge of a particular topic, and have minimal real-world application.

9. **Step 9- *Becoming proficient*:** Users begin to understand the language of the situation or text, especially if this language uses technical or unfamiliar vernacular. Understanding terminology and use of product language is one of the first building blocks that form the foundation of the model. This is also when users start to understand the step-by-step procedures required to perform basic operations to get some desired outcome. Here, they are usually learning the bread-and-butter operations of the product so they can receive enough value to motivate them to keep using it. Later, they will be able to build on this knowledge.
10. **Step 10- Make connections between mental models.** We need to know full context and not isolated facts. Rather than holding siloed mental models in your mind, consider how they interact, connect and complement one another.
11. **Step 11-Think, what light the mental model can bring on the situation, idea, text , speech etc.** Do I see the situation, idea, text, speech etc, in the new way? What new way can I see the situation? Does This Makes easier to make a decision in my life?
12. **Step 12- Think very carefully, if each chosen Mental model applicable to situation, idea, text, speech etc.**
13. **Step 13-Use the Chosen Mental Models tool.** The canvas, below, will help you to identify high-value areas where new mental models can make the biggest impact on your work and life. It also provides a simple framework to begin to embed using your chosen models.
14. **Step 14-*Mastering*:** Users build on the core step-by-step tasks they already know, expanding their knowledge to more complex or niche capabilities. If they make it this far they most likely have an accurate understanding of most or all of the language the product uses.
15. **Step 15-Regularly reassess their priorities without fear of changing them.** They don't fall prey to inertia.
16. **Step 16-Be biased toward taking action—not lazily deferring.** If they encounter a mental model they value, they make sure they use it.
17. **Step 17-Be always looking to prove yourselves wrong.** Ego should not get in the way of mental models.

18. Step 18-Accepting that all models are wrong in certain instances is not a license to ignore the facts. As a society, we should search for better answers, look for evidence, and strive to increase the accuracy of our knowledge.

- I. That's not to say all lenses (or models) apply to all problems. They don't. And it's not to say that having more lenses (or models) will be a advantage in all problems. It won't. This is why learning and applying the Great Mental Models is a process that takes some work. But the truth is, most problems are multidimensional, and thus having more lenses often offers significant help with the problems we are facing.**
- II. The more you use them, the more you will be able to build the knowledge of indicators that can trigger the use of the most appropriate model. Using and failing, as long as you acknowledge, reflect, and learn from it, is also how you build your repertoire. You need to be deliberate about choosing the models you will use in a situation. As you use them, a great practice is to record and reflect. That way you can get better at both choosing models and applying them. Take the time to notice how you applied them, what the process was like, and what the results were. Over time you will develop your knowledge of which situations are best tackled through which models. Don't give up on a model if it doesn't help you right away. Learn more about it, and try to figure out exactly why it didn't work. It may be that you have to improve your understanding. Or there were aspects of the situation that you did not consider. Or that your focus was on the wrong variable.**

- 19. Step 19-After all Analysis, decide what models are the most suitable after all to apply.**
- 20. Step 20-Apply The Mental Model in Real Life or Reality, and let the world do the work for You.**

Step 143-Transdisciplinary Thinking

1. **Step 1 Define Transdisciplinary Thinking.** Transdisciplinary For one of the first times was stated in a 1973 OECD report on environmental education. Transdisciplinarity describes a study that focuses on issues that cross the borders of two or even more disciplines “when a common set of axioms prevail, related to but lying beyond and complementing traditional disciplines. With the other word, principles or techniques originally developed by one discipline but now commonly used by others. Transdisciplinarity is probably the most desirable and yet difficult to obtain form of integrated research. Some researchers are, in fact, skeptical about whether it can be achieved at all. For example, Pohl observes that the extent of the requirements for transdisciplinary research suggest that it is to some extent “a ‘megalomaniac’ endeavour.” In addition, Tress *et al.* note that, despite the best intentions, “Transdisciplinary landscape research is an exception, even interdisciplinarity is seldom reached.” Such studies seek a transcendence of disciplinary perspectives (in some cases “redrawing the disciplinary map” into a broader framework in “true systemic fashion” that involves practical engagement with “local and regional issues of concern”. In this sense transdisciplinarity is the highest form of integrated project, involving not only multiple disciplines, but also multiple *non-academic participants* (e.g., land managers, user groups, the general public) in a manner that combines interdisciplinarity with participatory approaches. Walter *et al.* suggest that transdisciplinary research is characterised by “a process of collaboration between scientists and non-scientists on a specific real world problem” and combines scientific research with the generation of decision-making capacity for the involved stakeholders or as Schmidt describes it a “problem with the problems”. While Mobjörk *et al.* suggest that transdisciplinarity can be divided into “consulting” (stakeholders are consulted but not incorporated in the research process) and “participatory” (stakeholders are incorporated and considered equally valuable) forms, we argue that non-participatory forms of transdisciplinarity are, in fact, interdisciplinarity as transdisciplinary approaches are widely defined by their engagement of non-scientists in the research process. The variety included in many transdisciplinary frameworks is largely the result of the strong problem solving

objectives of the research and the need for flexible methodologies in transdisciplinary research is driven by this problem solving approach as “methodologies employed in transdisciplinary research needs to correspond to and reflect the problem and context under investigation”. To ensure that all relevant disciplines are represented within transdisciplinary projects, a pluralistic (rather than unitary) approach to methodology is standard. This focus on the problem, rather than the disciplines excludes the possibility of unidirectional research. As Hadorn *et al.* observe, within a transdisciplinary environment, no single discipline has intellectual precedence. In fact, some researchers go so far as to equate transdisciplinarity with holism, arguing that “It solves disagreements and differences in knowledge and scientific approaches through dialectic thinking, not majority rule, tradition or compromise” [5] or that it is “a different manner of seeing the world, more systematic and more holistic”. As such, Rapport suggests that “the essential element of transdisciplinarity is ‘transcendence’—a creative process whereby a framework for characterizing larger level processes transcends frameworks used to characterize the parts”. (For more on creativity and serendipity involved in research that reaches beyond a single discipline.) Political ecology is an example of a transdisciplinary sub-discipline that has emerged from the transcendence of a number of disciplines—and has existed under the umbrella of a larger disciplinary body (Geography) since the 1970s though others associate with interdisciplinary work . In promoting a holistic perspective, transdisciplinarity requires considerable effort on the part of engaged researchers to open up their research to alternative ways of thinking, or, as Giri suggests to “overcome one’s disciplinary chauvinism” and develop “an openness to perspectives of other disciplines”. The adoption of a holistic perspective leads to another key feature of transdisciplinarity—that it has high aims of reconstituting and rearranging the nature of disciplinary knowledge thus creating, through fusion across arbitrary intellectual boundaries, new synthesized disciplines with which to address the real-world problems at hand explicitly through collaboration. The demands placed on researchers to collaborate and ‘overcome chauvinism’ means that transdisciplinarity, of all the integrated research forms, has a strong focus on the building of personal relationships and joint understandings. Establishing trust and understanding between researchers within the projects is thus a key objective of building

transdisciplinary capacity. Transdisciplinary working produces a new, novel form or way of working beyond the original disciplinary boundaries. It's like a cake: you can no longer see the form of the ingredients as they have taken on a different shape and flavour. Let's review the process that Pinker has laid out, one that we might think about emulating as we examine the causes of complex phenomena in human systems:

- I. We observe an interesting phenomenon in need of explanation, one we feel capable of exploring.
- II. We propose and examine competing hypotheses that would explain the phenomena (set up in a falsifiable way, in harmony with the divide between science and pseudoscience laid out for us by the great Karl Popper).
- III. We examine a cross-section of: Empirical data relating to the phenomena; sensible qualitative inference (from multiple fields/disciplines, the more fundamental the better), and finally; "Demonstrable" aspects of nature we are nearly certain about, arising from controlled experiment or other rigorous sources of knowledge ranging from engineering to biology to cognitive neuroscience.
- IV. Listen and Apply The Following Books:
 - **How we can Assess the Level of Interdisciplinarity and Transdisciplinarity of Academic Institutions? By Mahmood Ramezanzade**
 - **Detection of Distributed Denial of Service (DDoS) Attacks in IOT Based Monitoring System of Banking Sector Using Machine Learning Models By Muhsmmmsf Shafiq**

2. Step 2-Do Work Required to Have an Opinion on Any Topic and Anything.

- I. Most people go through life not really getting any smarter. Why? They simply won't do the work required. It's easy to come home, sit on the couch, watch TV, and zone out until bedtime rolls around. But that's not going to help you get smarter.
- II. You can acquire knowledge if you want it. In fact, there is a simple formula, which if followed is almost certain to make you smarter over time. Simple but not easy. It involves a lot of hard work. "The best thing a human being can do is to help another human being know more."
- III. How to Get Smarter Read. A lot. Warren Buffett says, "I just sit in my office and read all day." What does that mean? He estimates that he spends 80% of his working day reading and thinking. When asked how to get smarter, Buffett once held up stacks of paper and said, "Read 500 pages like this every week. That's how knowledge builds up, like compound interest." All of us can build our knowledge, but most of us won't put in the effort. "Go to bed smarter than when you woke up."
- IV. Knowledge accumulation as an acquired, rather than natural, genius. And he'd give all the credit to the studying;.
- V. The first thing they always do is tell you what they think. When someone has an opinion about everything, they want to share it with you. They often tout stats and research as if they had an imaginary checklist of facts they need to be able to rattle off to establish themselves as an expert in a field they actually know very little about. Because they have an opinion on everything, they are quick to judge others – for their lack of opinions, for their lack of knowledge, for their lack of outrage ... the list goes on.
- VI. People who have opinions about everything barf so much noise that it's hard to find the signal. Your brain has to work overtime to figure out if they did the work to come up with their opinions themselves or if they're simply regurgitating some op-ed in a newspaper. Over time, opinionated people also end up in their own prisons and they try to take you with them.
- VII. The problem comes from how we see the world. Our opinions are often rooted in how we think the world should work, according to our morals, values, and principles. If we see the world through the lens of our opinions, much of what happens will not agree with us. This is feedback, and how we respond to this feedback is key.

VIII. While we all hold an opinion on almost everything. Have I do the work required to have an opinion on any Subject? Never allow myself to have an opinion on anything that I don't know the other side's argument better than they do. The work required to have an opinion is very hard part, have I avoid it?

- I have to do the reading.
- I have to do Thinking and mental model.
- I have to talk to competent people and understand their arguments.
- I have to think about the key variables and how they interact over time.
- I have to listen and chase down arguments that run counter to your views.
- I have to think about how you might be fooling yourself.
- I have to see the issue from multiple perspectives.
- I have to think.
- I need to become your most intelligent critic and have the intellectual honesty to kill some of your best-loved ideas.

IX. If that sounds like a lot of work, just say, "I don't have an opinion on that; why don't you tell me how you got to have such a firm one? It sounds like I could learn something."

X. We all are learning, modifying, or destroying ideas all the time. Rapid destruction of your ideas when the time is right is one of the most valuable qualities you can acquire. You must force yourself to consider arguments on the other side. As Rabbi Moses ben Maimon (1135–1204), commonly known as Maimonides, said: "Teach thy tongue to say I do not know, and thou shalt progress."

XI. Doing the work required to hold an opinion means you can argue against yourself better than others can. Only then can you say, "I can hold this view because I can't find anyone else who can argue better against my view." Great thinkers, like Charles Darwin, did the work. And it's one of the biggest reasons he's buried at Westminster Abbey.

XII. Doing the work counteracts our natural desire to seek out only information that confirms what we believe we know. When Darwin encountered opinions or facts that ran contrary to his ideas, he endeavored not only to listen but also not to rest until he could either argue better than his challengers or understand how the fact fit. Darwin did the work. It's wasn't easy, but that's the point.

XIII. The difference between the people who do the work and the people who just reel off memorized opinions is huge. When you do the work, you can answer the next question. You know when to follow the rules and when they'll get you in trouble. When I did my postgraduate I was surrounded by people who could answer the test questions. They got good grades — actually, they got *great* grades but an odd thing happened after school: a lot of those people couldn't apply their knowledge to problems they hadn't seen before. They were chauffeurs — they knew the memorized answer. They couldn't answer the next question. We're all chauffeurs in some aspects of our lives. This is why understanding your circle of competence is so critical to living a rational life.

- Circle of Competence:

- **Circle Of Competence**-Understanding my Circle of Competence helps to avoid problems, identify opportunities for improvement and learn from Others. Circle of Competence is simple: Each of us, through experience or study, has built up useful knowledge on certain areas of the world. Some areas are understood by most of us, while some areas require a lot more specialty to evaluate. For example, most of us have a basic understanding of the economics of a restaurant: You rent or buy space, spend money to outfit the place and then hire employees to seat, serve, cook, and clean. (And, if you don't want to do it yourself, manage.) From there, it's a matter of generating enough traffic and setting the appropriate prices to generate a profit on the food and drinks you serve —after all of your operating expenses have been paid. Though the cuisine, atmosphere, and price points will vary by restaurant, they all have to follow the same economic formula. That basic knowledge, along with some understanding of accounting and a little bit of study, would enable one to evaluate and invest in any number of restaurants and restaurant chains, public or private. It's not all that complicated. Far more important is to honestly define what we do know and stick to those areas. Our circle of competence can be widened, but only slowly and over time. Mistakes are most often made when straying from this discipline. Where should we devote our limited time in life, to achieve the most success? So, the simple takeaway here is clear. If you want to improve your odds of success in life and business, then define the perimeter of your circle of competence, and operate inside. Over time,

work to expand that circle but never fool yourself about where it stands today, and never be afraid to say “I don’t know.”

- The Two Types of Knowledge: The Max Planck and Chauffeur Test: How to distinguish between the two types of knowledge: real knowledge and pretend knowledge.
 - The first type of knowledge is real. It can’t be bought. It can’t be copied. If you want real knowledge you need to earn it. One is Planck knowledge, the people who really know. They’ve paid the dues, they have the aptitude. You are going to have the problem in your life of getting the responsibility into the people with the Planck knowledge and away from the people with the chauffeur knowledge. Real knowledge comes when people do the work. The problem is that it’s difficult to separate the two. This is the Batesian Mimicry problem. One way to tease out the difference between Planck and chauffeur knowledge is to ask them why.
 - The second type of knowledge is copied. On the surface you know the answer but you lack the understanding to show your work. Then we’ve got chauffeur knowledge. They’ve learned the talk. They may have a big head of hair, they may have fine temper in the voice, they’ll make a hell of an impression. But in the end, all they have is chauffeur knowledge. I think I’ve just described practically every politician in the United States. We have the people who don’t do the work — they pretend. While they’ve learned to put on a good show, they lack understanding. They can’t answer questions that don’t rely on memorization. They can’t explain things without using jargon or vague terms. They have no idea how things interact. They can’t predict the consequences. The problem is that it’s difficult to separate the two. This is the Batesian Mimicry problem. One way to tease out the difference between Planck and chauffeur knowledge is to ask them why.
 - How To Distinguish Real Knowledge and Fake Knowledge. With journalists, it is more difficult. Some have acquired true knowledge. Often they are veteran reporters who have specialized for years in a clearly defined area. They make a serious effort to understand the

complexity of a subject and to communicate it. They tend to write long articles that highlight a variety of cases and exceptions. The majority of journalists, however, fall into the category of chauffeur. They conjure up articles off the tops of their heads or, rather, from Google searches. Their texts are one-sided, short, and— often as compensation for their patchy knowledge. The same superficiality is present in business. The larger a company, the more the CEO is expected to possess “star quality.” Dedication, solemnity, and reliability are undervalued, at least at the top. Too often shareholders and business journalists seem to believe that showmanship will deliver better results, which is obviously not the case. One way to guard against this is to understand your circle of competence. Dobelli concludes with some advice worth taking to heart. Be on the lookout for chauffeur knowledge. Do not confuse the company spokesperson, the ringmaster, the newscaster, the schmoozer, the verbiage vendor, or the cliché generator with those who possess true knowledge. How do you recognize the difference? There is a clear indicator: True experts recognize the limits of what they know and what they do not know. If they find themselves outside their circle of competence, they keep quiet or simply say, “I don’t know.” This they utter unapologetically, even with a certain pride. From chauffeurs, we hear every line except this.

- Batesian Mimicry Problem. Batesian Mimicry: Why Copycats Are Successful. Mimic and the Real Thing:
 - “There’s two kinds of snakes you come across. There’s the Texas Coral Snake, and the Mexican Milk Snake, and they both look exactly alike. The Texas Coral Snake is dangerous, it’s venomous, it can kill you in a minute. The Mexican Milk Snake can’t do anything to you; it’s an impostor.”How is it that these two look alike? It’s due to a phenomenon called Batesian Mimicry.
 - In the 1850s, the naturalist Henry Walter Bates found a certain set of butterflies who were clearly *not* of the same species but whose wings looked almost the same to the naked eye. After thinking it over, Bates eventually figured out what was going on: While the butterflies which were toxic to potential predators (the “models”) were able to operate freely and relatively unmolested, there had also developed a “mimic” population of butterflies which wasn’t toxic at all, yet still went untouched! In fact, biologists eventually figured out that the more toxic and dangerous the “model” was and the more frequently they appeared in the local population, the easier it was for its “mimics” to get by! Predators simply wouldn’t take the risk of mixing up the two. If there aren’t as many “models” around or they aren’t that dangerous, the mimics have a harder time.
 - This is a wonderful model, and in the practical world we live in, a similar phenomenon abounds: Copycats or “pretenders to the throne” are often very effective, very convincing “mimics” of the true champions. They dress the part, they talk the talk, and they know what buttons to push. But in the end, they are merely chauffeurs. We see a very Batesian effect at work: The more impressive the “model,” the more effective its mimics can be in convincing people they too are impressive, and in all the same ways. But for every Warren Buffett (just one by our count), there has been many “future” Warren Buffett’s. For every Steve Jobs, there have been many “next” Steve Jobs’. In fact, sometimes even just *appearances* can be quite convincing: now-disgraced Theranos founder Elizabeth Holmes was very fond of wearing a very Steve Jobsian black turtleneck outfit. Because they can be very convincing, we must be wise enough to watch out for Batesian mimicry

— even in ourselves. This brings up an interesting, at times paradoxical, question: Who can best tell the difference between a Coral Snake and its Mimics? The Coral Snake itself. The real thing knows a fake. It's worth taking the time to work on learning all the big ideas you can find, not just the ones you want to learn. In that search, you'll find a host of big winners you didn't even know existed.

XIV. The ability to destroy your ideas rapidly instead of slowly when the occasion is right is one of the most valuable things. You have to work hard on it. Ask yourself what are the arguments on the other side. It's bad to have an opinion you're proud of if you can't state the arguments for the other side better than your opponents. This is a great mental discipline.

XV. Doing the work means you can't make up your mind with a high degree of confidence right away. Doing the work forces you to challenge your beliefs because you have to argue from both sides. You become the somewhat impartial judge. What's on trial is your opinion. If you want to work with the world rather than against it, one of the major leverage points you can put effort into is how to distinguish between the people who've done the work and those who haven't. The ones who have will pass the Batesian Mimicry Test.

XVI. As Per Kobe Bryant statement: Trivial things should not be taken your attention. The attentions should be focused on things that is very important. Anything outside of the most important things in life, you should not have time for. You Should love the challenge in life, and always be curious, if you can be at the top , as these greats in that area. Always focus on one thing and not multiple things, this gives an edge and advantage over other people, who focusing on multiple things in life. The World Becomes a library to you, to be better at your craft.: Everything you see whether TV show I saw, Books, Journals, I read, whether discussion, debate I listen, people I talk to. Everything was done to try to learn to become better at the craft your focusing. When you have this point of you, then the world becomes your library to help you to become better at the craft.

XVII. Have the best work ethic on daily basis. This is everyday process, and try to figure it out, the strengths and weaknesses of my position and opposing person position.

XVIII. Always look at the reality of the situation, and do not let the emotion cloud the situation and the execution. Always be in the present and the moment.

XIX. We read a lot. I don't know anyone who's wise who doesn't read a lot. But that's not enough: You have to have a temperament to grab ideas and do sensible things. Most people don't grab the right ideas or don't know what to do with them.

XX. Another way to get smarter, outside of reading, is to surround yourself with people who are not afraid to challenge your ideas. "Develop into a lifelong self-learner through voracious reading; cultivate curiosity and strive to become a little wiser every day."

3. Step 3- Slow Down

I. Do Not Rush Thinking Process, and Do it Very Slow.

II. Do Not Rush Any Task I will do At Any Time.

III. Listen and Apply Book “The Slow Fix Solve Problems, Work Smarter, and Live Better in a World Addicted to Speed”

IV. Listen and Apply Book *In Praise Of Slowness Challenging the Cult of Speed BY Carl Honore.

- We live in a world scarce of understanding and abundant with information. We complain that we never have any free time yet we seek distraction. If work can't distract us, we distract ourselves. We crave perpetual stimulation and motion. We're so busy that our free time comes in 20 second bursts, just long enough for us to read the gist and assume we understand. If we are to synthesize learning and understanding we need time to think.
- The modern storm of bits and stimulation, relents only when we sleep. (And then only if we remember to turn off the phone.) Lost in all of this is the art of stillness. We live in a world with more information than ever and yet we understand less. We have come into the belief that the simple act of reading confers understanding. Worse, most of our reading is elementary reading, or skimming — a far cry from syntopical reading, which seems more fertile for the mind willing to do the work.
- But that's just it. We don't want, or can't find the time, to do the work that's required to hold an opinion. It's much easier to simply read the opinions of another and let them think for us.
- Understanding comes from focusing, chewing, and relentlessly ragging on a problem. It comes with false starts, dead ends, and frustration. Thinking requires time and space. It's slow. It means saying I don't know. In short, thinking is everything the modern workplace is designed to eradicate.
- We're expected to have an opinion about everything and yet our time to think is near zero. We hold more opinions than ever but have less understanding. We don't even understand ourselves. How could it be otherwise?
- As Milan Kundera wrote in his 1996 novella Slowness, “When things happen too fast, nobody can be certain about anything, about anything at all, not even about himself. “In our fast-moving modern world, it always

seems that the time-train is pulling out of the station just as we reach the platform. No matter how fast we go, no matter how cleverly we schedule, there are never enough hours in the day.”

- Carl Honore, wrote a book, In Praise of Slowness: Challenging the Cult of Speed, to explore why we’re always in such a rush, what if anything is the cure for time-sickness, and whether it’s desirable to slow down. The book is not an all-out declaration of war against speed. Speed has helped to remake our world in ways that are wonderful and liberating. Who wants to live without the Internet or jet travel? The problem is that our love of speed, our obsession with doing more and more in less and less time, has gone too far; it has turned into an addiction, a kind of idolatry. Even when speed starts to backfire, we invoke the go-faster gospel.
- When we rush, we skim the surface, and fail to make real connections with the world or other people.” Moreover we don’t make connections with ideas. We don’t synthesize. We don’t test theories over time. We don’t play with ideas.
- The implications on thinking are fascinating. We are all fast-thinkers now. We have forgotten how to look forward to things, and how to enjoy the moment when they arrive. Restaurants report that hurried diners increasingly pay the bill and order a taxi while eating dessert. Many fans leave sporting events early, no matter how close the score is, simply to steal a march on the traffic. Then there is the curse of multi-tasking. Doing two things at once seems so clever, so efficient, so modern. And yet what it often means is doing two things not very well. Like many people, I read the paper while watching TV— and find that I get less out of both. In this media-drenched, data-rich, channel-surfing, computer-gaming age, we have lost the art of doing nothing, of shutting out the background noise and distractions, of slowing down and simply being alone with our thoughts. Boredom— the word itself hardly existed 150 years ago— is a modern invention. Remove all stimulation, and we fidget, panic and look for something, anything, to do to make use of the time. When did you last see someone just gazing out the window on a train? Everyone is too busy reading the paper, playing video games, listening to iPods, working on the laptop, yammering into mobile phones. Instead of thinking deeply, or letting an idea simmer in the back of the mind, our instinct now is to reach for the

nearest sound bite. In modern warfare, correspondents in the field and pundits in the studio spew out instant analyses of events as they occur. Often their insights turn out to be wrong. But that hardly matters nowadays: in the land of speed, the man with the instant response is king. With satellite feeds and twenty-four-hour news channels, the electronic media is dominated by what one French sociologist dubbed “le fast thinker”— a person who can, without skipping a beat, summon up a glib answer to any question.

- Fast eats time. One consequence of fast is that we make poor decision after poor decision. Those decisions don’t go away never to be seen again. It’s not like we make a bad decision and we’re done with it. No, the consequences are much worse. Poor decisions eat time. They come back to haunt you. They create issue after issue. They feed into the perpetual motion machine of busyness. And in a culture where people wear busyness as a badge of honor bad decisions actually lead us to think that we’re doing more.

V. Do The Tasks Slowly, and Step By Step.

VI. The Art of Slowing down and Do Not Rush Anything.

- The Art of Stillness is a persuasively argued case for the pleasures of slowing down and being in one place. Today we’re going faster and faster in search of contentment and meaning. This is largely a recipe for ensuring we will never be happy. We have the sense, too often, of running at top speed and never being able to catch up.
- Too many of us see going nowhere as turning away from something rather than turning towards something.
- Going nowhere isn’t about turning your back on the world; it’s about stepping away now and then so that you can see the world more clearly and love it more deeply. “There is nothing either good or bad, but thinking makes it so.”
- The idea behind choosing to sit still long enough to learn about yourself is simple and has been around for ages. Marcus Aurelius and Epictetus reminded us many millennia ago that it’s how we respond to our experiences, not the experiences themselves, which shape us.

- The greatest weapon against stress is our ability to choose one thought over another. Part of making better decisions is making time to think. Something that few of us are able to do.
- “Our creations come not when we’re out in the world, gathering impressions, but when we’re sitting still, turning those impressions into sentences.

4. Step 4- Do not Multitask.

- I. Of course you can do more than one thing at once. The catch is you can’t do more more than one thing at once that requires concentration. You can walk and chew gum, but you can’t write an email and a report at the same time. When you’re doing two things at once that are cognitively demanding, what you’re really doing is switching back and forth very quickly from one task to another.
- II. There is a mental cost—called a switching cost—to all of this multitasking. But that’s not all it makes deep thinking impossible.
- III. I think people that multitask pay a huge price. They think they’re being extra productive, and I think they’re (out of their mind). I use the metaphor of the one-legged man in the ass-kicking contest. I think when you multi-task so much, you don’t have time to think about anything deeply. You’re giving the world an advantage you shouldn’t do. Practically everybody is drifting into that mistake. Concentrating hard on something that is important is. I can’t succeed at all without doing it. I did not succeed in life by intelligence. I succeeded because I have a long attention span.
- IV. It sounds counter-intuitive but if you want to increase discretionary time and reduce stress you need to schedule time to think. The tiny fragments of time many of us find ourselves with have a negative effect on our ability to think deeply about a problem. Furthermore they impede our ability to learn — we stay at a surface level and never move into a deep understanding. Deresiewicz warns: “You simply cannot (think) in bursts of 20 seconds at a time, constantly interrupted by Facebook messages or Twitter tweets, or fiddling with your iPod, or watching something on YouTube.”
- V. The opposite approach is to focus on a problem or subject and try to achieve a deep fluency. How many of us, however, have time? We don’t do the work required to have an opinion. Instead we operate with surface knowledge. We tackle problems with the first thought that comes to mind. Because we make a

poor initial decision, we spend countless hours attempting to correct it. No wonder we have no time to think. We're not heeding the advice of Joseph Tussman and letting the world do the work for us.

VI. Listen and Apply The Following Books:

- **The Multitasking Mind By Dario Saliveci**

5. Step 5-What is Thinking/

I. Thinking Rate

- You can't force yourself to think faster. If you try, you're likely to end up making much worse decisions. Here's how to improve the actual quality of your decisions instead of chasing hacks to speed them up.
- When the product of your job is your decisions, you might find yourself wanting to be able to make more decisions more quickly so you can be more productive overall.
- Chasing speed is a flawed approach. Because decisions—at least good ones—don't come out of thin air. They're supported by a lot of thinking.

II. Beyond The Hurry Culture

- Everyone is trying to work faster at all times, and they pressure everyone around them to work faster, too.
- All of these things increase pressure in the work environment and repeatedly reinforce the "hurry up!" message. They make managers feel like they're moving things along faster. That way if work isn't getting done, it's not their fault. But, DeMarco writes, they don't lead to meaningful changes in behavior that make the whole organization more productive. Speeding up often results in poor decisions that create future problems.
- The reason more pressure doesn't mean better productivity is that the rate at which we think is fixed. We can't force ourselves to start making faster decisions right now just because we're faced with an unrealistic deadline. DeMarco writes, *"Think rate is fixed. No matter what you do, no matter how hard you try, you can't pick up the pace of thinking."*

III. Elements of Effective Thinking

- **Understand Deeply.** Don't face complex issues head-on; first understand simple ideas deeply. Clear the clutter and expose what is really important. Be brutally honest about what you know and don't know. Then see what's missing, identify the gaps, and fill them in. Let go of bias, prejudice, and preconceived notions. There are degrees to understanding (it's not just a yes-or-no proposition) and you can always heighten yours. Rock-solid understanding is the foundation for success.
- **Make Mistakes.** Fail to succeed. Intentionally get it wrong to inevitably get it even more right. Mistakes are great teachers — they highlight unforeseen opportunities and holes in your understanding. They also show you which way to turn next, and they ignite your imagination.
- **Raise Questions.** Constantly create questions to clarify and extend your understanding. What's the real question? Working on the wrong questions can waste a lifetime. Ideas are in the air — the right questions will bring them out and help you see connections that otherwise would have been invisible.
- **Follow the Flow of Ideas.** Look back to see where ideas came from and then look ahead to discover where those ideas may lead. A new idea is a beginning, not an end. Ideas are rare— milk them. Following the consequences of small ideas can result in big payoffs. These are the four basic building blocks for effective thinking. The fifth is Change.
- **Change.** The unchanging element is change— by mastering the first four elements, you can change the way you think and learn. You can always improve, grow, and extract more out of your education, yourself, and the way you live your life. Change is the universal constant that allows you to get the most out of living and learning.

6. Step 6-Collect As Many mental models as Possible from diverse domains and academic disciplines That I think is suitable for my situation or Information provided by the Text, Book, Speech etc. Research a broad range of industries to identify mental models that can be integrated and Most Suitable into area of work or focus. In identifying the Great Mental Models we have to look for elementary principles, the ideas from multiple disciplines that form a time tested foundation, these mental models would be from Elementary Mental Models to most Advanced Mental Models. It may seem counterintuitive, to work on developing knowledge that is available to everyone, but the universe works in the same way no matter where you are in it or how you think the universe should be working. What you need is to understand the principles, so that when the details change you are still able to identify what is really going on. Listen and Follow Every Book on Each Mental models.

A. General Mental Models For Thinking.

I. The Great Mental Models Volume 1 By Fs Blog.

- The Map is Not The Territory.
- Circle of Competence.
- The first Principles Thinking.
- Though Experiment.
- Second Order Thinking.
- Probabilistic Thinking.
- Inversion.
- Occam's Razor.
- Hanlon's Razor.
- Supporting Ideas.
- Falsifiability.
- Necessity and Sufficiency.
- Causation vs Correlation.

II. The Great Mental Models Volume 2 By Fs Blog.

- Physics.
 - Relativity.
 - Reciprocity.
 - Thermodynamics.
 - Inertia.

- Friction and Viscosity.
- Velocity
- Leverage.

- Chemistry.
 - Activation Energy.
 - Catalysts.
 - Alloying,

- Biology.
 - Evolution Part One: Natural Selection and Extinction.
 - Evolution Part two: Adaptation Rate and The Red Queen Effect.
 - Supporting Idea: Competition.
 - Ecosystem.
 - Niche.
 - Self Preservation.
 - Replication.
 - Cooperation.
 - Supporting Idea: Dunbar's Number.
 - Hierarchical Organisation.
 - Incentives.
 - Tendency to Minimize energy Output.

III. The Great Mental Models Volume 3 By Fs Blog.

- Systems.
 - Feedback Loops.
 - Equilibrium.
 - Bottlenecks.
 - Scale.
 - Margin of Safety.
 - Churn.
 - Algorithms.
 - Supporting Idea: Complex Adaptive Systems.
 - Critical mass.

- Emergence.
- Supporting Idea: Chaos Dynamics.
- Irreducibility.
- Law of Diminishing Returns.
- Mathematics.
 - Supporting Idea: Distribution.
 - Compounding.
 - Supporting Idea; Network Effect.
 - Sampling.
 - Randomness.
 - Supporting idea: Pareto Principle.
 - Regression to the mean.
 - Multiplying by ZERO.
 - Equivalence.
 - Supporting idea: order of Magnitude.
 - Surface Area.
 - Global and local Maxima.

- 7. Step 7-Getting familiar:** At this starting point, users decide if they can use an existing mental model (maybe one used for another similar product) or if they need to start from scratch. The existing mental model may be void of useful knowledge or worse, contain the wrong knowledge. The core components missing at this stage include an understanding of the language the product uses and the actionable steps needed to complete core tasks.
- 8. Step 8-Apply simple criteria to which mental models you use.** When selecting mental models to include into your own latticework, consider whether they support you to better understand yourself and/or the world around you, so you might better effective and impactful action. Also Mental models do two things: they help you assess how things work and they help you make better decisions. Ask some Questions:
 - I. How long has this model been around?** As a general rule, mental models which have been around for a long time (such as Occam's razor) will have been subjected to a great deal of scrutiny. Time is an excellent curator, trimming away inefficient ideas. A mental model which is new may not be particularly refined or versatile. Many of our mental models originate from Ancient Greece and Rome, meaning they have to be functional to have survived this long.
 - II. Is it a representation of reality?** In other words, does it reflect the real world? Or is it based on abstractions?
 - III. Does this model apply to multiple areas?** The more elastic a model is, the more valuable it is to learn about. (Of course, be careful not to apply the model where it doesn't belong. Mind Feynman: "You must not fool yourself, and you're the easiest person to fool.")
 - IV. How did this model originate?** Many mental models arise from scientific or mathematical concepts. The more fundamental the domain, the more likely the model is to be true and lasting.
 - V. Is it based on first principles?** A first principle is a foundational concept which cannot be deduced from any other concept and must be known.
 - VI. Does it require infinite regress?** Infinite regress refers to something which is justified by principles, which themselves require justification by other principles. A model based on infinite regress is likely to

required extensive knowledge of a particular topic, and have minimal real-world application.

9. **Step 9- *Becoming proficient*:** Users begin to understand the language of the situation or text, especially if this language uses technical or unfamiliar vernacular. Understanding terminology and use of product language is one of the first building blocks that form the foundation of the model. This is also when users start to understand the step-by-step procedures required to perform basic operations to get some desired outcome. Here, they are usually learning the bread-and-butter operations of the product so they can receive enough value to motivate them to keep using it. Later, they will be able to build on this knowledge.
10. **Step 10- Make connections between mental models.** We need to know full context and not isolated facts. Rather than holding siloed mental models in your mind, consider how they interact, connect and complement one another.
11. **Step 11-Think, what light the mental model can bring on the situation, idea, text , speech etc.** Do I see the situation, idea, text, speech etc, in the new way? What new way can I see the situation? Does This Makes easier to make a decision in my life?
12. **Step 12- Think very carefully, if each chosen Mental model applicable to situation, idea, text, speech etc.**
13. **Step 13-Use the Chosen Mental Models tool.** The canvas, below, will help you to identify high-value areas where new mental models can make the biggest impact on your work and life. It also provides a simple framework to begin to embed using your chosen models.
14. **Step 14-*Mastering*:** Users build on the core step-by-step tasks they already know, expanding their knowledge to more complex or niche capabilities. If they make it this far they most likely have an accurate understanding of most or all of the language the product uses.
15. **Step 15-Regularly reassess their priorities without fear of changing them.** They don't fall prey to inertia.
16. **Step 16-Be biased toward taking action—not lazily deferring.** If they encounter a mental model they value, they make sure they use it.
17. **Step 17-Be always looking to prove yourselves wrong.** Ego should not get in the way of mental models.

18. Step 18-Accepting that all models are wrong in certain instances is not a license to ignore the facts. As a society, we should search for better answers, look for evidence, and strive to increase the accuracy of our knowledge.

- I. That's not to say all lenses (or models) apply to all problems. They don't. And it's not to say that having more lenses (or models) will be a advantage in all problems. It won't. This is why learning and applying the Great Mental Models is a process that takes some work. But the truth is, most problems are multidimensional, and thus having more lenses often offers significant help with the problems we are facing.**
- II. The more you use them, the more you will be able to build the knowledge of indicators that can trigger the use of the most appropriate model. Using and failing, as long as you acknowledge, reflect, and learn from it, is also how you build your repertoire. You need to be deliberate about choosing the models you will use in a situation. As you use them, a great practice is to record and reflect. That way you can get better at both choosing models and applying them. Take the time to notice how you applied them, what the process was like, and what the results were. Over time you will develop your knowledge of which situations are best tackled through which models. Don't give up on a model if it doesn't help you right away. Learn more about it, and try to figure out exactly why it didn't work. It may be that you have to improve your understanding. Or there were aspects of the situation that you did not consider. Or that your focus was on the wrong variable.**

- 19. Step 19-After all Analysis, decide what models are the most suitable after all to apply.**
- 20. Step 20-Apply The Mental Model in Real Life or Reality, and let the world do the work for You.**

Step 144-Journaling

1. **Step 1-So keep a journal. Write your experiences down. When you identify a model at work in the world, write that down too. Then you can explore the applications you've observed, and start being more in control of the models you use every day. For instance, instead of falling victim to confirmation bias, you will be able to step back and see it at work in yourself and others. Once you get practice, you will start to naturally apply models as you go through your life, from reading the news to contemplating a career move. As we have seen, we can run into problems when we apply models to situations in which they don't fit. If a model works, we must invest the time and energy into understanding why it worked so we know when to use**

Step 145-Letting The World Do The Work For You

1. Listen and Apply book
 - I. This Explains Everything_ Deep, Beautiful, and Elegant Theories of How the World Works
2. **The world never tells you that you're wrong; it only gives you outcomes.**
3. **Don't force. Don't resist. Have a beginner's mind. Let the world teach you.**
4. **Reality will do a lot of the work for us if we simply align with it. Most of the time we're simply adding friction because we want the world to work in the way we think it should.**
5. **If you don't see the world the way it is, you'll think it works in a way that it doesn't and make terrible mistakes. The key to getting what you want out of life is to identify how the world works and align yourself accordingly. This is hard because we think the world should work the way we see it. The word "should" is important. Because we think the world should work in a way that it doesn't, our approach is suboptimal. What the pupil must learn, if he learns anything at all, is that the world will do most of the work for you, provided you cooperate with it by identifying how it really works and aligning with those realities. If we do not let the world teach us, it teaches us a lesson. Joseph Tussman**
6. When an outcome is not what you want it to be, things get tough. You can ignore the result and continue to think that you're right. This protects your ego. It also carries the risk of your continuing to believe something that isn't true. Alternatively, you can calibrate your believability on the subject at hand by lowering the odds that you're right. For example, maybe you gave yourself an 85 out of 100 for the ability to hold a firm opinion on this subject, and now you lower your score to 75. If the world continues to provide undesirable outcomes, eventually you get the hint and change your beliefs. Finally, you can give up your opinions and just respond to the world as it is. This option is the hardest.
7. You do not create the way the world works, you can only align yourself with it. It takes a lot of work to align ourselves with reality. When we don't get the outcome we're seeking, the last place we look is inside ourselves. Instead, we blame others or

circumstances. If you want to align yourself with reality, you have to work at it and care about it. There are two keys to aligning yourself with how the world really works: accepting feedback and stopping bargaining.

- I. We let people, not results, guide our behavior. The world tries to tell us when we don't see it the way it is. The problem is we don't listen to the world. Instead, we let others tell us what's right and wrong, what works, and what doesn't. Common actions get common results. Most of our actions come from others. We want what they want. Even worse, we employ the same actions to get it. This isn't always wrong. If you're just starting, the quickest path to average is to copy. If you want better results than average, you're going to have to iterate. Doing something different means we might look like a fool, and we do not want to look like a fool. Iterating means trying something new, it means you might fail. Show me a person who's afraid to look bad, and I'll show you a person you can beat every time. If we do what everyone else is doing, we're going to get the same results that everyone else is getting. Different results demand different actions. If you can't really fail, you can't really succeed. Let results, not popularity, determine your actions. If you're doing something that doesn't get you the results you want, try something new. If you're doing something that seems to work, keep doing it. Consistently repeat successful actions.
- II. Bargaining with the world doesn't work. A lot of otherwise smart people know what they're doing isn't getting the results they want, but because they think the world *should* work in a way that it doesn't, they keep repeating them hoping for different results. If you are this person, see it for what it is, and change your actions. The feedback from the world is often painful. Often, it is this very pain that causes us to no longer delude ourselves with how the world should work and accept how it does work. If you can learn to accept the world for how it is, before suffering, you'll go faster and further. Outcome over ego. If you think you know how the world works but you're doing something that gets suboptimal results because it *should* work a different way, you don't really know how the world works. Rational people take feedback from the world. If you want to know how someone sees the world, look at their actions. In the end, it's all your fault. You are accountable for your outcomes. When you take responsibility for your outcomes, you naturally accept feedback from reality. When you get feedback from reality, you adjust your behavior.

- III. As Per Kobe Bryant statement: Trivial things should not be taken your attention. The attentions should be focused on things that is very important. Anything outside of the most important things in life, you should not have time for. You Should love the challenge in life, and always be curious, if you can be at the top , as these greats in that area. Always focus on one thing and not multiple things, this gives an edge and advantage over other people, who focusing on multiple things in life. The World Becomes a library to you, to be better at your craft.: Everything you see whether TV show I saw, Books, Journals, I read, whether discussion, debate I listen, people I talk to. Everything was done to try to learn to become better at the craft your focusing. When you have this point of you, then the world becomes your library to help you to become better at the craft.
- IV. Have the best work ethic on daily basis. This is everyday process, and try to figure it out, the strengths and weaknesses of my position and opposing person position.
- V. Always look at the reality of the situation, and do not let the emotion cloud the situation and the execution. Always be in the present and the moment.
- VI. If you understand the world as it really is, not as you'd wish it to be, you will begin to make better decisions almost immediately. Once you start making better decisions the results compound. Better initial decisions free up your time, reduce your stress, allowing you to spend more time with your family and leave your competition in the dust.
- VII. How can we best understand the world as it is? Acquiring knowledge can be a very daunting task. If you think of the mind as a toolbox, we're only as good as the tools at our disposal. A carpenter doesn't show up to work with an empty toolbox. Not only do they want as many tools in their toolbox as possible, but they want to know how to use them. Having more tools and the knowledge of how to use them means they can tackle more problems. Try as we might, we cannot build a house with only a hammer. If you're a knowledge worker, you're a carpenter. But your tools aren't bought at a store and they don't come in a red box that you carry around. Mental tools are the big ideas from multiple disciplines, and we store them in our mind. And if we have a lot of tools and the knowledge required to wield them properly, we can start to synthesize how the world works and make better decisions when confronted with problems.
- VIII. This is how we understand and deal with reality. The tools you put into your toolbox are Mental Models. Mental models are a framework for understanding

how the world really works. They help you grasp new ideas quickly, identify patterns before anyone else and shift your perspective with ease. Mental Models allow us to make better decisions, scramble out of bad situations, and think critically. If you want to understand reality you must look at a problem in multiple dimensions — how could it be otherwise? Getting to this level of understanding requires having a lot of tools and knowing how to use them. You knew there was a hitch right? We need to change our fast-food diet of information consumption and adopt the healthier diet of knowledge that changes slowly over time. While changing diets isn't easy, it can be incredibly rewarding: more time, less stress, and being better at your job. The costs, however, are short term pain for long-term gain. You must change how you think.

- IX. 2nd Order Thinking. One example of a model we can immediately conceptualize and use to improve our ability to make better decisions is something we can borrow from ecology called second-order thinking. The simple way to conceptualize this is to ask yourself "If I do X, what will happen *after* that?". I sum this up using the ecologist Garrett Hardin's simple question: "And then what?" A lot of people forget about higher order effects — second and third-order effects or higher. I've been in a lot of meetings where decisions are made and very few people think to the second level, let alone the third. Rather, what typically happens is called first conclusion bias. The brain shuts down and stops thinking at the first idea that comes to mind that seems to address the problem as you understand it. We don't often realize that our first thoughts are usually not even our own thoughts. They usually belong to someone else. We understand the sound-byte but we haven't done the hard work of real thinking. After we reach the first conclusion, our minds often shut down. We don't seek evidence that would contradict our conclusion. We don't ask ourselves what the likely result of this solution would be — we don't ask ourselves "And then what?" We don't ask what other solutions might be even *more* optimal. For example, consider a hypothetical organization that decides to change their incentive systems. They come up with a costly new system that requires substantial changes to the current system. Only they don't consider (or even understand) the problems that the *new* system is likely to create. It's possible they've created more problems than they've solved — only now there are *different* problems they must put their head down to solve. Optically, they "reorganize their incentive programs," but practically, they've simply expended energy to stay in place. Another, perhaps more complicated,

example is when a salesman comes into a company and offers you a software program he claims will lower your operating costs and increase your profits. He's got all these beautiful charts on how much more competitive you'll be and how it will improve everything. This is exactly what you need because your compensation is based on increasing profits. You're sold. Then second-order thinking kicks in and you dare to ask how much of those cost savings are going to go to you and how much will eventually end up benefits enjoyed by customers? To a large extent, that depends on the business you're in. However, you can be damn sure the salesman is now knocking on your competitor's door and telling them you just bought their product and if they want to remain competitive they better purchase it too. Eventually, you all have the new software and no one is truly better off. Thus, in the manner of a crowd of people standing on their tip-toes at a parade, all competitors spend the money but none of them win: The salesman wins and the customer wins. We know, thanks to people like Garrett Hardin, Howard Marks, Charlie Munger, Peter Kaufman, and disciplines like ecology, that there are second and third-order effects. This is how the world really works. It just isn't always a comfortable reality. Understanding how the world works isn't easy and it shouldn't be. It's hard work. If it were easy, everyone would do it. And it's not for everyone. Sometimes, if your goal is to maximize utility, you should focus on getting very, very good in a narrow area and becoming an expert, accepting that you will make many mistakes outside of that domain. But for most, it's extremely helpful to understand the forces at play outside of their narrow area of expertise. Because when you think about it, how could reality be anything other than a synthesis of multiple factors? How could it possibly be otherwise?

- X. When our mental models line up with reality, they help us avoid problems. However, they also cause problems when they don't line up with reality as we think something that isn't true.
- XI. We must be open to other perspectives if we truly want to understand the results of our actions. Despite feeling that we've got all the information, if we're on the ship, the fish in the ocean has more he can share. The second flaw is ego. Many of us tend to have too much invested in our opinions of ourselves to see the world's feedback—the feedback we need to update our beliefs about reality. This creates a profound ignorance that keeps us banging our head against the wall over and over again. Our inability to learn from the world because of our ego happens for many reasons, but two are worth mentioning here. First, we're so

afraid about what others will say about us that we fail to put our ideas out there and subject them to criticism. This way we can always be right. Second, if we do put our ideas out there and they are criticized, our ego steps in to protect us. We become invested in defending instead of upgrading our ideas. The third flaw is distance. The further we are from the results of our decisions, the easier it is to keep our current views rather than update them. When you put your hand on a hot stove, you quickly learn the natural consequence. You pay the price for your mistakes. Since you are a pain avoiding creature, you update your view. Before you touch another stove, you check to see if it's hot. But you don't just learn a micro lesson that applies in one situation. Instead, you draw a general abstraction, one that tells you to check before touching anything that could potentially be hot. Organizations over a certain size often remove us from the direct consequences of our decisions. When we make decisions that other people carry out, we are one or more levels removed and may not immediately be able to update our understanding

Step 146 Journaling

1. **Step 1-So keep a journal. Write your experiences down. When you identify a model at work in the world, write that down too. Then you can explore the applications you've observed, and start being more in control of the models you use every day. For instance, instead of falling victim to confirmation bias, you will be able to step back and see it at work in yourself and others. Once you get practice, you will start to naturally apply models as you go through your life, from reading the news to contemplating a career move. As we have seen, we can run into problems when we apply models to situations in which they don't fit. If a model works, we must invest the time and energy into understanding why it worked so we know when to use**
2. **Visualization- Remember, visualization will never compensate for the work undone. You cannot visualize lies. All the strategies I employ to answer the simple questions and win the mind game are effective because I put in work. It's a lot more than mind over matter. It takes relentless self-discipline to schedule suffering into your day, every day, but if you do, you'll find that at the other end of that suffering is a whole other life just waiting for you.**
 - **First, he would learn everything he could about it and prepare physically as best as possible.**
 - **Once the physical prep was done, he'd take care of the mental prep with visualization.**
 - **Since he knew almost everything about his challenge, he visualized what awaited him. He would imagine himself struggling, suffering, and eventually succeeding.**
 - **Preparing himself this way helped him pace his future, and improve the odds of avoiding quitting.**
 - **Side note: visualization is great, but it's no substitute for preparation.**

Step 147-Letting The World Do The Work For You

1. Listen and Apply book
 - I. This Explains Everything_ Deep, Beautiful, and Elegant Theories of How the World Works
2. **The world never tells you that you're wrong; it only gives you outcomes.**
3. **Don't force. Don't resist. Have a beginner's mind. Let the world teach you.**
4. **Reality will do a lot of the work for us if we simply align with it. Most of the time we're simply adding friction because we want the world to work in the way we think it should.**
5. **If you don't see the world the way it is, you'll think it works in a way that it doesn't and make terrible mistakes. The key to getting what you want out of life is to identify how the world works and align yourself accordingly. This is hard because we think the world should work the way we see it. The word "should" is important. Because we think the world should work in a way that it doesn't, our approach is suboptimal. What the pupil must learn, if he learns anything at all, is that the world will do most of the work for you, provided you cooperate with it by identifying how it really works and aligning with those realities. If we do not let the world teach us, it teaches us a lesson. Joseph Tussman**
6. When an outcome is not what you want it to be, things get tough. You can ignore the result and continue to think that you're right. This protects your ego. It also carries the risk of your continuing to believe something that isn't true. Alternatively, you can calibrate your believability on the subject at hand by lowering the odds that you're right. For example, maybe you gave yourself an 85 out of 100 for the ability to hold a firm opinion on this subject, and now you lower your score to 75. If the world continues to provide undesirable outcomes, eventually you get the hint and change your beliefs. Finally, you can give up your opinions and just respond to the world as it is. This option is the hardest.
7. You do not create the way the world works, you can only align yourself with it. It takes a lot of work to align ourselves with reality. When we don't get the outcome we're seeking, the last place we look is inside ourselves. Instead, we blame others or

circumstances. If you want to align yourself with reality, you have to work at it and care about it. There are two keys to aligning yourself with how the world really works: accepting feedback and stopping bargaining.

- I. We let people, not results, guide our behavior. The world tries to tell us when we don't see it the way it is. The problem is we don't listen to the world. Instead, we let others tell us what's right and wrong, what works, and what doesn't. Common actions get common results. Most of our actions come from others. We want what they want. Even worse, we employ the same actions to get it. This isn't always wrong. If you're just starting, the quickest path to average is to copy. If you want better results than average, you're going to have to iterate. Doing something different means we might look like a fool, and we do not want to look like a fool. Iterating means trying something new, it means you might fail. Show me a person who's afraid to look bad, and I'll show you a person you can beat every time. If we do what everyone else is doing, we're going to get the same results that everyone else is getting. Different results demand different actions. If you can't really fail, you can't really succeed. Let results, not popularity, determine your actions. If you're doing something that doesn't get you the results you want, try something new. If you're doing something that seems to work, keep doing it. Consistently repeat successful actions.
- II. Bargaining with the world doesn't work. A lot of otherwise smart people know what they're doing isn't getting the results they want, but because they think the world *should* work in a way that it doesn't, they keep repeating them hoping for different results. If you are this person, see it for what it is, and change your actions. The feedback from the world is often painful. Often, it is this very pain that causes us to no longer delude ourselves with how the world should work and accept how it does work. If you can learn to accept the world for how it is, before suffering, you'll go faster and further. Outcome over ego. If you think you know how the world works but you're doing something that gets suboptimal results because it *should* work a different way, you don't really know how the world works. Rational people take feedback from the world. If you want to know how someone sees the world, look at their actions. In the end, it's all your fault. You are accountable for your outcomes. When you take responsibility for your outcomes, you naturally accept feedback from reality. When you get feedback from reality, you adjust your behavior.

- III. As Per Kobe Bryant statement: Trivial things should not be taken your attention. The attentions should be focused on things that is very important. Anything outside of the most important things in life, you should not have time for. You Should love the challenge in life, and always be curious, if you can be at the top , as these greats in that area. Always focus on one thing and not multiple things, this gives an edge and advantage over other people, who focusing on multiple things in life. The World Becomes a library to you, to be better at your craft.: Everything you see whether TV show I saw, Books, Journals, I read, whether discussion, debate I listen, people I talk to. Everything was done to try to learn to become better at the craft your focusing. When you have this point of you, then the world becomes your library to help you to become better at the craft.
- IV. Have the best work ethic on daily basis. This is everyday process, and try to figure it out, the strengths and weaknesses of my position and opposing person position.
- V. Always look at the reality of the situation, and do not let the emotion cloud the situation and the execution. Always be in the present and the moment.
- VI. If you understand the world as it really is, not as you'd wish it to be, you will begin to make better decisions almost immediately. Once you start making better decisions the results compound. Better initial decisions free up your time, reduce your stress, allowing you to spend more time with your family and leave your competition in the dust.
- VII. How can we best understand the world as it is? Acquiring knowledge can be a very daunting task. If you think of the mind as a toolbox, we're only as good as the tools at our disposal. A carpenter doesn't show up to work with an empty toolbox. Not only do they want as many tools in their toolbox as possible, but they want to know how to use them. Having more tools and the knowledge of how to use them means they can tackle more problems. Try as we might, we cannot build a house with only a hammer. If you're a knowledge worker, you're a carpenter. But your tools aren't bought at a store and they don't come in a red box that you carry around. Mental tools are the big ideas from multiple disciplines, and we store them in our mind. And if we have a lot of tools and the knowledge required to wield them properly, we can start to synthesize how the world works and make better decisions when confronted with problems.
- VIII. This is how we understand and deal with reality. The tools you put into your toolbox are Mental Models. Mental models are a framework for understanding

how the world really works. They help you grasp new ideas quickly, identify patterns before anyone else and shift your perspective with ease. Mental Models allow us to make better decisions, scramble out of bad situations, and think critically. If you want to understand reality you must look at a problem in multiple dimensions — how could it be otherwise? Getting to this level of understanding requires having a lot of tools and knowing how to use them. You knew there was a hitch right? We need to change our fast-food diet of information consumption and adopt the healthier diet of knowledge that changes slowly over time. While changing diets isn't easy, it can be incredibly rewarding: more time, less stress, and being better at your job. The costs, however, are short term pain for long-term gain. You must change how you think.

- IX. 2nd Order Thinking. One example of a model we can immediately conceptualize and use to improve our ability to make better decisions is something we can borrow from ecology called second-order thinking. The simple way to conceptualize this is to ask yourself "If I do X, what will happen *after* that?". I sum this up using the ecologist Garrett Hardin's simple question: "And then what?" A lot of people forget about higher order effects — second and third-order effects or higher. I've been in a lot of meetings where decisions are made and very few people think to the second level, let alone the third. Rather, what typically happens is called first conclusion bias. The brain shuts down and stops thinking at the first idea that comes to mind that seems to address the problem as you understand it. We don't often realize that our first thoughts are usually not even our own thoughts. They usually belong to someone else. We understand the sound-byte but we haven't done the hard work of real thinking. After we reach the first conclusion, our minds often shut down. We don't seek evidence that would contradict our conclusion. We don't ask ourselves what the likely result of this solution would be — we don't ask ourselves "And then what?" We don't ask what other solutions might be even *more* optimal. For example, consider a hypothetical organization that decides to change their incentive systems. They come up with a costly new system that requires substantial changes to the current system. Only they don't consider (or even understand) the problems that the *new* system is likely to create. It's possible they've created more problems than they've solved — only now there are *different* problems they must put their head down to solve. Optically, they "reorganize their incentive programs," but practically, they've simply expended energy to stay in place. Another, perhaps more complicated,

example is when a salesman comes into a company and offers you a software program he claims will lower your operating costs and increase your profits. He's got all these beautiful charts on how much more competitive you'll be and how it will improve everything. This is exactly what you need because your compensation is based on increasing profits. You're sold. Then second-order thinking kicks in and you dare to ask how much of those cost savings are going to go to you and how much will eventually end up benefits enjoyed by customers? To a large extent, that depends on the business you're in. However, you can be damn sure the salesman is now knocking on your competitor's door and telling them you just bought their product and if they want to remain competitive they better purchase it too. Eventually, you all have the new software and no one is truly better off. Thus, in the manner of a crowd of people standing on their tip-toes at a parade, all competitors spend the money but none of them win: The salesman wins and the customer wins. We know, thanks to people like Garrett Hardin, Howard Marks, Charlie Munger, Peter Kaufman, and disciplines like ecology, that there are second and third-order effects. This is how the world really works. It just isn't always a comfortable reality. Understanding how the world works isn't easy and it shouldn't be. It's hard work. If it were easy, everyone would do it. And it's not for everyone. Sometimes, if your goal is to maximize utility, you should focus on getting very, very good in a narrow area and becoming an expert, accepting that you will make many mistakes outside of that domain. But for most, it's extremely helpful to understand the forces at play outside of their narrow area of expertise. Because when you think about it, how could reality be anything other than a synthesis of multiple factors? How could it possibly be otherwise?

- X. When our mental models line up with reality, they help us avoid problems. However, they also cause problems when they don't line up with reality as we think something that isn't true.
- XI. We must be open to other perspectives if we truly want to understand the results of our actions. Despite feeling that we've got all the information, if we're on the ship, the fish in the ocean has more he can share. The second flaw is ego. Many of us tend to have too much invested in our opinions of ourselves to see the world's feedback—the feedback we need to update our beliefs about reality. This creates a profound ignorance that keeps us banging our head against the wall over and over again. Our inability to learn from the world because of our ego happens for many reasons, but two are worth mentioning here. First, we're so

afraid about what others will say about us that we fail to put our ideas out there and subject them to criticism. This way we can always be right. Second, if we do put our ideas out there and they are criticized, our ego steps in to protect us. We become invested in defending instead of upgrading our ideas. The third flaw is distance. The further we are from the results of our decisions, the easier it is to keep our current views rather than update them. When you put your hand on a hot stove, you quickly learn the natural consequence. You pay the price for your mistakes. Since you are a pain avoiding creature, you update your view. Before you touch another stove, you check to see if it's hot. But you don't just learn a micro lesson that applies in one situation. Instead, you draw a general abstraction, one that tells you to check before touching anything that could potentially be hot. Organizations over a certain size often remove us from the direct consequences of our decisions. When we make decisions that other people carry out, we are one or more levels removed and may not immediately be able to update our understanding.

PART 20: Deep Work and Performance

Step 148-Performance Books

1. **Listen, Follow And Apply Rules of Reading Part 1 to 18, before looking Performance.**
2. **Listen, Follow and Apply the following Books.**
 - A. Managing Employee Performance and Reward_ Concepts, Practices, Strategies.
 - B. Performance Management and Performance Measurement.
 - C. PERFORMANCE MANAGEMENT Performance management key strategies and practical.
 - D. PERFORMANCE MANAGEMENT Performance Management, A New Approach for Driving Business Results.
 - E. Execution_ The Discipline of Getting Things Done.
 - F. High Commitment High Performance_ How to Build A Resilient Organization for Sustained Advantage.
 - G. Key Performance Indicators (KPI) _ Developing, Implementing, and Using Winning KPIs.
 - H. Key Performance Indicators (KPI) The 75 measures every manager needs to know.
 - I. Key performance indicators for government and non profit agencies _ implementing winning KPIs.
 - J. Performance Management and Performance Measurement.
 - K. The Little Book of Big Management Theories_ ... and how to use them.

Step 149- Tiny Gains. Massive Results.

When we want to improve ourselves, we often pursue dramatic changes with little success. A better idea is to go for small, incremental improvements that add up over time.

Self-motivated, self-starting individuals are incredibly motivated to find their weaknesses. It's not far-fetched to say that some of us actually seek to make ourselves perfect — rational, calculating beings making the right type of decisions at just the right times. But we've learned from Star Trek; we don't look to eliminate emotion either and turn ourselves into Mr. Spock. We want *just the right amount* of emotion in our lives.

People often overestimate what they can accomplish in one year. But they greatly underestimate what they could accomplish in five years.

— Peter drucker

If we're night owls, we seek to become early risers. (Ben Franklin did it!). If we're procrastinators, we look to become doers. If we're always late to meetings, we look to be early to meetings. We want to eliminate our weaknesses and become a little More.

This is, of course, a laudable goal. But the self-starters among us have probably all run into the same problem: We don't actually follow through on the things we know will make us better. We don't eat the broccoli. We get a little too robotic. We get up at 8:30 when we said we'd do 5:30 from here on out. We leave that essay until the last second even though that was never going to happen again. We're five minutes late. We don't become lore at all, and the failure to get there makes us feel like less.

The culprit is the thought that any important change happens quickly. It doesn't matter whether you're trying to get up early or pick up and implement the Psychology of Human Misjudgment. Anything important happens slowly.

From Potential to Useful

And why should it be otherwise? If you were to truly understand, in-depth, and apply the *Psychology of Human Misjudgment* to your dealings, you'd be way far out ahead of your peers and your former self. The advantage of understanding human nature is incredible. But it takes deep, repeated study and a long gestation period to get there. It takes applying the ideas to the world, feeling them out, forgetting them, redoubling yourself, and trying again. Not giving up when you forget or fail. It is through the process of *refinement* that one learns new habits and ideas.

The visual mental model I like for self-improvement is imagining something like a Lathe.

A *lathe*, for the non-engineer, is a tool that molds a piece of material into some shapely form. A machinist would use a lathe to take a hunk of metal and turn it into a usable engine part, for example. The lathe takes something with *potential* and shapes it into something *useful* by slowly refining it and shaving away the excess.

Compounding works in other areas besides money.

The way I think about it, if I can get 5% wiser and better every year, then I will be about twice as wise as I am now in less than 15 years. (Go ahead, grab your calculators.) In less than 30 years, my return will be 4x. This is how the non-gifted among us can surpass otherwise more intelligent people.

Tiny Improvements, Massive Results

Tiny improvements add up to *massive* differences.

Compounding works in other areas besides money. And we want to compound worldly wisdom.

These little mental tricks like the Lathe and the idea of 5% yearly improvement are just ways to remind myself that I'm not going to wake up wiser/nicer/healthier/smarter tomorrow morning or the morning after. And just as importantly, if I backslide on a goal I've set or I forget something I thought I'd learned well, that it's really not the end of the world. I don't need to give up and call it hopeless. All I have to do is figure out where I slipped, re-double my efforts, and go after it again. All I need is 5% a year to become 4x better in my adult lifetime.

The truth is that whatever bad habits you have or whatever things you're struggling to learn, there's probably a good reason. Your biology and your experiences to date have set you in stone to a certain extent, and the older you are, the more likely that is to be true. The chains of habit are too light to be felt until they are too heavy to be broken. Billion-dollar industries have been built on convincing you that it's *easy* to make big changes or to get a lot wiser and better. But it honestly isn't. It's hard work.

Yet any study of great individuals reveals that the work is worth doing.

So just imagine if you could make slightly better decisions every year. Whether it's 5% better consideration of *all* of your decisions, or making 5% of your decisions differently, or some permutation thereof, it doesn't really matter. Every year you'll look back at some part of your old self and wonder how you could've been so dumb. And one day, in less than 30 years, you'll look back and see your old self as almost unrecognizably stupid.

What more could you ask for?

Step 150 - The Ultimate Deliberate Practice Guide: How to Be the Best

Everything You Need to Know to Improve Your Performance at Anything—For Beginners and Experts

Deliberate practice is the best technique for achieving expert performance in every field—including writing, teaching, sports, programming, music, medicine, therapy, chess, and business. But there's much more to deliberate practice than 10,000 hours. Read this to learn how to accelerate your learning, overcome the "OK" plateau, turn experience into expertise, and enhance your focus.

What is deliberate practice?

*"Engaged in the creative process we feel more alive than ever, because we are making something and not merely consuming, masters of the small reality we create. In doing this work, we are in fact creating ourselves." —Robert Greene, *Mastery**

Deliberate practice is what turns amateurs into professionals. Across every field, deliberate practice is what creates top performers and what they use to stay at the top of their game. It's absolutely essential for expert performance.

As a general concept, "practice" means preparing. It's the act of repeatedly performing certain activities with the intention of improving a specific associated skill. We rehearse what to do in low-pressure situations so we'll be better when we use a skill in situations where something is actually at stake, such as in a competition or in the workplace. Although this definition may seem obvious, it's crucial to distinguish between doing something and practicing it, because they're not always synonymous.

The key distinction between doing and practicing is that we're only practicing something when we do it in a way that makes us better at it—or at least with that intention.

Deliberate practice means practicing with a clear awareness of the specific components of a skill we're aiming to improve and exactly how to improve them. Unlike regular practice, in which we work on a skill by repeating it again and again until it becomes almost mindless, deliberate practice is a laser-focused activity. It requires us to pay unwavering attention to what we're doing at any given moment and whether it's an improvement or not.

Geoff Colvin summarizes deliberate practice as such in *Talent Is Overrated*:

Deliberate practice is characterized by several elements, each worth examining. It is activity designed specifically to improve performance, often with a teacher's help; it can be repeated a lot; feedback on results is continuously available; it's highly demanding mentally, whether the activity is purely intellectual, such as chess or business-related activities, or heavily physical, such as sports; and it isn't much fun.

The extraordinary power of deliberate practice is that it aims at constant progress. Practitioners are not content with repeating a skill at the same level. They have metrics for measuring their performance. And they aspire to see those metrics get continuously better. While engaging in deliberate practice, we are always looking for errors or areas of weakness. Once we identify one, we establish a plan for improving it. If one approach doesn't work, we keep trying new ones until something does.

Using deliberate practice, we can overcome many limitations that we might view as fixed. We can go further than we might even think possible when we begin. Deliberate practice creates new physical and mental capabilities—it doesn't just leverage existing ones.

The more we engage in deliberate practice, the greater our capabilities become. Our minds and bodies are far more malleable than we usually realize.

Deliberate practice is a universal technique, and you can employ it for whatever you're trying to be the best (or just get a little bit better) at. It's easiest to apply to competitive fields with clear measurements and standards, including music, dance, football/soccer, cricket, hockey, basketball, golf, horse riding, swimming, and chess.

But deliberate practice is also invaluable for improving performance in fields such as teaching, nursing, surgery, therapy, programming, trading, and investing. It can even accelerate your progress in widely applicable skills such as writing, decision-making, leadership, studying, and spoken communication.

The key in any area is to identify objective standards for performance, study top performers, and then design practice activities reflecting what they do. Recent decades have seen dramatic leaps in what people are capable of doing in many fields. The explanation for this is that we're getting better at understanding and applying the principles of deliberate practice. As a field advances, people can learn from the best of what those who came before them figured out. The result is that now average high-schoolers achieve athletic feats and children advance to levels of musical prowess that would have seemed unthinkable a century earlier. And there's little evidence to suggest we've reached the limits of our physical or mental abilities in any area whatsoever.

Many of us spend a lot of time each week practicing different skills in our lives and work. But we don't automatically get better just because we repeat the same actions and

behaviors, even if we spend hours per day doing it. Research suggests that in areas such as medicine, people with many years of experience are often no better than novices—and may even be worse.

If we want to improve a skill, we need to know *what* exactly has to change and what might get us there. Otherwise, we plateau.

Some people will tell you it's only possible for anyone to improve at anything through deliberate practice, and any other sort of practice is a waste of time. This is an exaggeration. In reality, regular practice works for reinforcing and maintaining skills. It can also help us improve skills, particularly in the early stages of learning something. However, deliberate practice *is* the only way to:

1. Reach expert-level performance and enjoy competitive success
2. Overcome plateaus in our skill level
3. Improve at a skill much faster than through regular practice

If you're just doing something for fun and don't care about constantly improving at it, you don't need deliberate practice. For example, maybe you like to go for a walk around a local park in the afternoons to clear your head. Although you're practicing that walk each time you go, you probably don't care about increasing your walking speed day by day. It's enough that the repetitions further ingrain the habit and help maintain a certain level of physical fitness. Not everything in life is a competition! But if you want to keep getting better at something as fast as possible or reach an expert level, deliberate practice is vital. Another important point to note is that deliberate practice isn't just a catchy name we came up with out of thin air. The term is largely attributed to Karl Anders Ericsson, one of the most influential figures of all time in the field of performance psychology. It's something many scientists have studied for decades. Everything we say here is supported by substantial academic research, particularly Ericsson's work.

We'll also debunk the numerous myths swirling around deliberate practice as a concept and reveal some of its significant limitations. So if you're looking for quick hacks for overnight success, you might want to look elsewhere. If you want a realistic roadmap for improving your performance, read on.

The elements of deliberate practice

“Life is not always a matter of holding good cards, but sometimes, playing a poor hand well.” —Jack London

In this section, we'll break down the fundamental elements of deliberate practice and exactly how to incorporate them into your practice sessions. As Ericsson wrote in *Peak*, *“No matter what the field, the most effective approach to improving performance is to follow a single set of principles.”* We'll explain why each component is crucial and how they apply to different fields, and we'll cover multiple ways to implement them depending on your goals.

Deliberate practice is structured and methodical

“Everyone has talent. What's rare is the courage to follow it to the dark places where it leads.” —Erica Jong

As humans, we're wired to want to do the easiest thing at all times in order to conserve energy. Put more simply, it's in our nature to be lazy. When we practice something a lot, we develop habits that become almost effortless to enact. While that's beneficial in many areas of our lives (and helps us survive), it's something we have to overcome in order to engage in deliberate practice. We can't expect constant improvement if we keep repeating the elements of a skill we already know how to do with ease. That's only enough if we're just having fun or want to reinforce our habits.

Deliberate practice is structured to improve specific elements of a skill through defined techniques. Practitioners focus above all on what they *can't* do. They seek out areas of weaknesses impacting their overall performance, then target those. At every stage, they set tailored, measurable goals in order to gauge whether their practice is effective at moving them forwards. Numbers are a deliberate practitioner's best friend.

If you want to reach an expert level of performance, you need to begin practice sessions with a plan in mind. You need to know what you're working on, why, and how you intend to improve it. You also need a way to tell if your improvement efforts aren't working and if you need to try a new tactic. Once you reach your goal for that particular component of the skill, it's time to identify a new area of weakness to work on next.

Having lots of little, realistic goals with a game plan for achieving them makes deliberate practice motivating. There's a sense of ongoing movement, yet the next step is always a realistic stretch. Day by day, the gains from deliberate practice may feel modest. But when we look back over a longer period of time, small bits of progress compound into gigantic leaps.

How to implement this: Take the skill you're aiming to improve and break it down into the smallest possible component parts. Make a plan for working through them in a logical order, beginning with the fundamentals, then building upon them. Decide which parts you'd like to master over the next month. Put your practice sessions in your calendar, then plan precisely which parts of the skill you're going to work on during each session.

Don't expect your plan to be perfect. You'll likely need to keep modifying it as you discover new elements or unexpected weaknesses. The most important thing is to always go into practice with a plan for what you're working on and how. Knowing what you're doing next is the best way to stay on track and avoid aimless time-wasting. That means seeking to keep figuring out what separates you from the next level of performance so you can concentrate on that.

Deliberate practice is challenging and uncomfortable

"One must develop an instinct for what one can just barely achieve through one's greatest efforts." —Albert Einstein (attributed)

Imagine the world from the perspective of a baby learning to walk for the first time. It's not usually an easy process. They need to develop a lot of new skills and capabilities. They need to build enough muscular strength to stand upright without support. And they need to learn how to coordinate their limbs well enough to move around. Along the way, a baby needs to develop numerous sub-skills, such as how to grip supports to pull themselves up. It likely takes thousands of attempts to master walking—as well as numerous, falls, collisions, and other mishaps. We might not remember the process as adults, but a baby learning to walk needs to spend many hours challenging themselves and moving incrementally out of their comfort zone.

If we want to use deliberate practice, we could do with learning a thing or two from babies. Deliberate practice isn't necessarily fun while we're doing it. In fact, most of the time it's a process of repeated frustration and failure. We have to fall down a dozen times for every step we take. That's the whole point.

Seeing as deliberate practice requires us to keep targeting our weakest areas, it means spending time doing stuff we're not good at. In the moment, that can feel pretty miserable. But the quickest route to improvement involves stepping outside of our comfort zones.

The reason why people who have spent decades doing something are not necessarily better than newbies is that they're liable to get complacent and stop pushing themselves. We need to keep attempting to do things that feel out of reach at the moment.

In his studies of elite violinists, Ericsson asked them to rate different practice activities by how enjoyable they were and how much they contributed to improving performance. Invariably, there was an inverse correlation between the usefulness of an activity and its enjoyability. As Ericsson puts it in *Peak*:

The reason that most people don't possess these extraordinary physical capabilities isn't because they don't have the capacity for them, but rather because they're satisfied to live in the comfortable rut of homeostasis and never do the work that is required to get out of it. They live in the world of "good enough." The same thing is true for all the mental activities we engage in.

Elsewhere in the book, he writes “*This is a fundamental truth about any sort of practice: If you never push yourself beyond your comfort zone, you will never improve.*” The interesting part is the more time you spend deliberately practicing, the more comfortable you'll become with being uncomfortable.

Daniel Coyle writes in *The Little Book of Talent*:

There is a place, right on the edge of your ability, where you learn best and fastest. It's called the sweet spot....The underlying pattern is the same: Seek out ways to stretch yourself. Play on the edges of your competence. As Albert Einstein said, "One must develop an instinct for what one can just barely achieve through one's greatest efforts."

The key word is 'barely.'

A quick way to assess if you're doing deliberate practice or just regular rote practice is to ask yourself if you ever feel bored or zone out during practice sessions. If the answer is yes, you're probably not practicing deliberately.

Deliberate practice isn't boring. Frustrating, yes. Maddening, yes. Annoying, even. But never boring. As soon as practicing a skill gets comfortable, it's time to up the stakes. Challenging yourself is about more than trying to work harder—it means doing new things. Pushing ourselves just beyond the limits of our abilities is uncomfortable, yet it's how we do our best—and indeed, it can be the source of some of our greatest moments of satisfaction. According to psychologist Mihaly Csikszentmihalyi, we often experience happiness as a result of entering a “flow” state, which occurs when we intensely focus on an activity that is challenging yet achievable. During moments of flow, we become so immersed in the activity that we lose any sense of time or of ourselves.

Noel Tichy, professor at the University of Michigan business school and the former chief of General Electric's famous management development center at Crotonville, puts the concept of practice into three zones: the comfort zone, the learning zone, and the panic zone.

Most of the time when we're practicing, we're really doing activities in our comfort zone. This doesn't help us improve because we can already do these activities easily. On the other hand, operating in the panic zone leaves us paralyzed, as the activities are too difficult and we don't know where to start. The only way to make progress is to operate in the learning zone, which are those activities that are just out of our reach.

Repetition inside the comfort zone does not equal deliberate practice. Deliberate practice requires that you operate in the learning zone and you repeat the activity a lot with feedback.

How to implement this: Each time you practice a component of a skill, aim to make it 10% harder than the level you find comfortable.

Once per month, have a practice session where you set yourself an incredibly ambitious stretch goal—not impossible, just well above your current level. Challenge yourself to see how close you can get to it. You might surprise yourself and find you perform far better than expected.

A common deliberate practice mistake is to plan a long practice session, then adjust the intensity of your practice to allow you to engage in a skill for the whole time. It's far more effective to engage in "sprints." Practice with the most intense focus you can manage for short periods of time, then take breaks. Seeing as you learn most when you stretch yourself beyond your current capabilities, shorter, more challenging practice periods are the way to go.

Deliberate practice requires rest and recovery time

"There is a time for many words, and there is also a time for sleep." —Homer, *The Odyssey*

Seeing as deliberate practice is so challenging, it's impossible to do it all day long. Across fields, top practitioners rarely spend more than around three to five hours per day on deliberate practice, at the high end. They may work for more hours than that per day, but few can sustain the mental energy to engage in deliberate practice for eight hours a day. Additional hours often result in diminishing negative returns, meaning more practice makes performance worse because it results in burnout. Geoff Colvin writes:

The work is so great that it seems no one can sustain it for very long. A finding that is remarkably consistent across disciplines is that four or five hours a day seems to be the upper limit of deliberate practice, and this is frequently accomplished in sessions lasting no more than an hour to ninety minutes.

Ericsson's studies of elite violinists found they often took afternoon naps and slept an average of eight hours per night, considerably more than the average person. They were highly aware of the importance of sleep.

Even fitting in a single hour per day of deliberate practice is ample time to make substantial improvements, especially when we're consistent with committing to it over the long haul. Continuous investments in success compound. In the long run, commitment pays off.

Not only do most deliberate practitioners not spend all day at it, they also devote a lot of time to recuperation and recovery. They sleep as much as their bodies need. They nap if necessary. They take frequent, refreshing breaks. Most of us understand that rest is necessary after physical activity. But we can underestimate its importance after mental activity, too. Deliberate practice needs to be sustainable for the long term. How long a person keeps at a skill is often far more important than how many hours a day they spend on it.

When you're practicing deliberately, truly practice. When you're recuperating, truly relax. No one can spend every waking hour on deliberate practice.

Sleep is a vital part of deliberate practice. Being asleep doesn't mean you're not still improving your skill. We consolidate memories at night, moving them from short-term to long-term memory. And we can't exactly benefit from deliberate practice sessions if we don't remember what we learn each time. Not only that, but sleep deprivation also results in a plethora of negative cognitive effects that impact performance. If we skimp on sleep, we're likely to forget far more of what we learn during deliberate practice sessions, rendering them less useful.

When you're not engaging in deliberate practice, your brain is still at work. During deliberate practice, we're in focused mode. When we let our minds wander freely while at rest, we're in diffuse mode. Although that time feels less productive, it's when we form connections and mull over problems. Both modes of thinking are equally valuable, but it's the harmony between them that matters. We can't maintain the effort of the focused mode for long. At some point, we need to relax and slip into the diffuse mode. Learning a complex skill—a language, a musical instrument, chess, a mental model—requires both modes to work together. We master the details in focused mode, then comprehend how everything fits together in diffuse mode. It's about combining creativity with execution.

How to implement this: Make a list of activities you can engage in without too much conscious thought, letting yourself daydream while you do them. Common examples include going for a walk, washing the dishes, taking a shower, free-writing in a journal,

playing with a toy like Lego, driving a familiar route, gardening, cooking, listening to music, or just gazing out the window. When you feel yourself getting tired or hitting a roadblock during deliberate practice, don't keep pushing for too long. You want to be stretching yourself, not exhausting yourself. Instead, switch to one of those more relaxing activities for at least five minutes. You'll likely come back to practice with new connections or at last feeling refreshed.

Deliberate practice involves constant feedback and measurement

"Deliberate practice is hard. It hurts. But it works. More of it equals better performance and tons of it equals great performance." —Geoff Colvin, *Talent Is Overrated*

Practicing something without knowing whether you are getting better is pointless. Yet that is what most of us do every day without thinking.

As we saw before, deliberate practice involves continuously stretching yourself to improve on weak areas of a skill. For that to work, practitioners require constant feedback about their current level of performance so they can identify what works for making it better.

What gets measured gets managed. To engage in deliberate practice, you need a way of measuring the most instructive metrics related to your performance. Seeing how those metrics change is the sole way to know if practice is working or not. Top performers across fields tend to spend time examining their past performance with care to identify areas for improvement. For example, a tennis player might film themselves playing a match so they can go through the footage frame by frame afterward. This provides valuable feedback, because they can figure out what might have held them back during weaker moments.

In fields such as sports and chess, measuring performance tends to be straightforward. In other areas such as business, measurements are harder to take, and there may be no established markers of success. The influence of random factors may also be stronger, making it less clear whether technique changes are actually having an influence or not. When you engage in deliberate practice, it's always important to be aware of how strongly correlated your practice and your performance are likely to be.

When measuring your performance, beware of vanity metrics. These are numbers that are easy to calculate and feel good to boost. But they don't actually move the needle towards the real improvements in performance that help you reach your goals. For example, let's say you're using deliberate practice to improve the skill of email marketing, as part of the wider goal of getting more customers for your business. The number of email subscribers is a vanity metric; the number of paying customers is a useful metric. It's completely possible to increase the former without a corresponding increase in the latter.

How to implement this: Identify the most significant metrics related to performance in your chosen skill and keep a record of them each time you practice. It's easy to fool yourself without a clear record of how you're doing. You might want to break the skill down into a few different parts to measure it, but make sure you're not fixating on vanity metrics.

Deliberate practice is most effective with the help of a coach or some kind of teacher

"The best teacher is not the one who knows most but the one who is most capable of reducing knowledge to that simple compound of the obvious and wonderful." —H.L. Mencken (attributed)

Deliberate practice is most effective when conducted with some kind of coach who can give feedback, point out errors, suggest techniques for improvement, and provide vital motivation. Although mastering any skill requires a lot of time engaging in solitary practice, working with a coach at least some of the time is incredibly valuable. In some fields such as sports and music, it's common for a coach to be present all of the time. But most top performers benefit from a combination of coaching and solitary practice.

When we look at the lives of people who achieved great things, we often find that those who did so at a young age or in a shorter time than expected benefited from having fantastic teachers. For example, physicist Werner Heisenberg had the epiphany that led to the formulation of matrix mechanics a mere five years after commencing serious study of physics. But he no doubt benefited from the mentorship of Niels Bohr and Max Born, two of the foremost physicists at the time.

Even people at the most elite levels of performance across fields can benefit from specialist coaching. Engaging in something and teaching that thing are separate skills in themselves. The best practitioners are not always the best teachers because teaching is a skill in itself.

Ericsson explained that *"the best way to get past any barrier is to come at it from a different direction, which is one reason it is useful to work with a teacher or coach."* We often make the same mistakes again and again because we simply don't realize what we're doing. Our performance falls into ruts and we can't figure out why we're running into the same problem yet again.

A coach can see your performance from the outside, without the influence of overconfidence and other biases. They can identify your blind spots. They can help you interpret key metrics and feedback.

Ericsson went on to say that *"even the most motivated and intelligent student will advance more quickly under the tutelage of someone who knows the best order in which to learn things, who understands and can demonstrate the proper way to perform various skills,*

who can provide useful feedback, and who can devise practice activities designed to overcome particular weaknesses.” An experienced coach will have worked with many people on the same skill so they’ll be able to advise on the best ways to structure practice. They’ll know when you’re just repeating what you find easy, and they’ll be able to push you to the next level.

Teachers or coaches see what you miss and make you aware of where you’re falling short. Geoff Colvin writes:

In some fields, especially intellectual ones such as the arts, sciences, and business, people may eventually become skilled enough to design their own practice. But anyone who thinks they’ve outgrown the benefits of a teacher’s help should at least question that view. There’s a reason why the world’s best golfers still go to teachers.

But what if you don’t have access to a coach? What if you don’t have the means to hire one or one isn’t available for your particular skill? In that case, it’s still possible to apply the same principles that make a coach useful by yourself. Top performers across fields build the skill of metacognition, essentially making it possible for them to coach themselves. Colvin explains:

The best performers observe themselves closely. They are in effect able to step outside themselves, monitor what is happening in their own minds, and ask how it’s going. Researchers call this metacognition—knowledge about your own knowledge, thinking about your own thinking. Top performers do this much more systematically than others do; it’s an established part of their routine.

...A critical part of self-evaluation is deciding what caused those errors. Average performers believe their errors were caused by factors outside their control: my opponent got lucky; the task was too hard; I just don’t have the natural ability for this. Top performers, by contrast, believe they are responsible for their errors. Note that this is not just a difference of personality or attitude. Recall that the best performers have set highly specific, technique-based goals and strategies for themselves; they have thought through exactly how they intend to achieve what they want. So when something doesn’t work, they can relate the failure to specific elements of their performance that may have misfired.

How to implement this: Don’t expect the same teacher to suit you forever. We usually need different teachers as our skill level progresses because we outgrow them. One attribute of a good teacher is that they know when to tell a student to move on. As we reach expert levels of performance, we need teachers who are themselves experts. If they’re always a step ahead, we can learn from their mistakes instead of making our own.

You get the best results from working with a coach if you show yourself to be receptive to constructive criticism, even if it's uncomfortable to hear. If you respond badly, you disincentivize them from telling you what's most useful to know. Top performers know the goal is to get better, not just to hear you're already great.

Deliberate practice requires intrinsic motivation

Persisting with deliberate practice despite its innate difficulty and discomfort requires a lot of motivation. But that motivation needs to be intrinsic, meaning that it comes from inside us because we find an activity enjoyable for its own sake. This is in contrast to extrinsic motivation, where we participate in an activity to gain an external reward or avoid a negative consequence. Yet another reason why rest is important for deliberate practice is because it helps sustain motivation.

Although deliberate practice can lead to external rewards for using a skill (such as winning a competition or getting a promotion), this should not be the sole reason for practicing it. Extrinsic motivation is unlikely to be enough to get us through the long period of struggle necessary to master a skill. Becoming proficient at anything means spending time failing repeatedly at it, during which there are few external rewards. But if we enjoy getting better for its own sake, we have more of a chance of persevering until our practice starts paying off. We can navigate obstacles because we want to see where the road might take us—the obstacles aren't roadblocks.

If you want to use deliberate practice to master a skill, you need to be willing to keep practicing it no matter what. Although brute force and rewarding yourself can be effective in the short run, it won't work forever. If you're planning to engage in deliberate practice to reach expert-level performance, make sure it's a prospect you feel excited about even if it won't always be fun.

Extrinsic motivation isn't always ineffective, however. People who engage in consistent, sustainable deliberate practice tend to be adept at knowing when and how they need to employ external incentives. It's important to reward yourself when you make progress in your practice and reflect on how far you've come, not just how far is left to go.

The need for intrinsic motivation is one reason why children who are pushed to develop a skill from a young age by their parents don't always end up reaching a high level of performance and often quit as soon as they can.

How to implement this: Make a list of the reasons you want to work on a skill and the benefits getting better at it might bring. Before you begin a deep practice session, reread the list to remind you of why you're bringing your full focus to something difficult. You could

also list some of the benefits you've experienced from it in the past or include quotes from top performers in your field you find inspiring. It might feel cheesy, but it can provide a powerful boost during particularly difficult practice moments. Try to focus on intrinsic reasons and benefits, such as feeling fulfilled.

Keep a "motivation diary" for one week (or longer if possible.) Try setting an alarm to go off every fifteen minutes during each practice session. When the alarm sounds, score your motivation level out of ten (or whichever scale you prefer.) At the end of the week, review your notes to look for any patterns. For example, you might find that you begin to feel demotivated once you've been practicing for more than an hour, or that you feel more motivated in the morning, or some other pattern. This information could be enlightening for planning future deliberate practice sessions, even if it may disrupt your focus at the time. Another method is to simply take notes each day, documenting your current level of motivation to work on your chosen skill. Pay attention to any recurring influences. For example, you might feel more motivated to improve your skill after speaking with a more proficient friend, but less motivated after a bad night's sleep.

One potent option for sustaining motivation is to find someone who can be a reliable cheerleader for you. In an Ask Me Anything session for [Farnam Street members](#), Tesla co-founder Marc Tarpenning explained that having a cofounder is vital for entrepreneurs because partnering with someone else helps sustain motivation. It's rare that both founders feel demotivated on the same day. So if one is struggling, the other can provide the encouragement needed to stay resilient. Having someone to provide extrinsic motivation when you need it can help you persevere at deliberate practice. Your cheerleader doesn't necessarily need to be working on the same skill themselves. They just need to understand your reasons and be willing to remind you of them when you start to doubt whether the hard work is worthwhile.

Deliberate practice takes time and can be a lifelong process

Although deliberate practice tends to result in much faster progress than normal practice, truly mastering a skill is a lifelong process. Reaching the top of a field can take years or even decades, depending on its competitiveness. As the bar for success in many areas keeps rising, more deliberate practice is required to stand out.

When we applaud the top people in any field, we often fail to appreciate that their success almost always came after many years of deliberate practice, which Robert Greene refers to in *Mastery* as "*a largely self-directed apprenticeship that lasts some five to ten years [and] receives little attention because it does not contain stories of great achievement or discovery.*" They may have ultimately benefited from a lucky break, but their extensive

preparation meant they were ready for it. Great achievements tend to come later in life or even near the ends of careers. Those who succeeded young started very young.

Throughout Ericsson's decades of research, he searched high and low for an example of a true prodigy: someone born with an innate, remarkable talent. He never found a single proven example. Instead, he discovered that people labeled as prodigies invariably put in enormous amounts of deliberate practice—they just often obscured it on purpose or started at a young age.

Although innate differences count when beginning to learn something (and people who begin with advantages may be more likely to persist), in the long run, deliberate practice always wins out.

David Shenk writes in *The Genius in All of Us*: “*Short-term intensity cannot replace long-term commitment. Many crucial changes take place over long periods of time. Physiologically, it's impossible to become great overnight.*”

According to psychologist John Hayes, creative genius tends to come after ten years of studying relevant knowledge and developing skills. Hayes referred to this as the “ten years of silence.” In a study of seventy-six composers with sufficient biographical data available listed in *The Lives of the Great Composers*, Hayes found they almost always created their first notable works (defined as being those for which at least five different recordings were available at the time) at least ten years after commencing a serious study of music. Just three of the five hundred works Hayes included in his sample were composed after less than a decade of preparation—and those were produced in years eight or nine. In additional studies, Hayes found similar patterns for painters and poets.

Later research reinforces Hayes' findings, and any casual survey of the lives of people widely considered to be geniuses tends to show a similar pattern. Making a breakthrough takes time. When it seems like someone was an overnight success, there's almost always a long period of silent deliberate practice preceding it. Innate talents are just a starting point. If we want to master a skill, we need to commit to working on it for a lengthy period of time, likely with few rewards. While there are no assurances that with struggle comes reward, without it the odds are lower.

Not only do world-class performers spend a long time getting good at their core skill, those in creative fields tend to produce an enormous quantity of work before gaining recognition. For every piece of work we're familiar with, there are likely dozens or even hundreds of others few people remember or ever saw.

For example, British prime minister Winston Churchill was known for his masterful public speaking. One of his best-known speeches “We Shall Fight on the Beaches,” given in

June 1940, displayed the extent of his command of oration and helped build morale at the time. But it's hard to overstate how prolific Churchill was as a speaker, giving an estimated 3,000 speeches during his political career. For every speech—an average of one per week between 1900 and 1955—he used deliberate practice to prepare. He engaged in focused rehearsals in front of a mirror, taking notes as he went to inform modifications. Churchill also left nothing to chance, planning his pauses and movements in advance. As well as devising his own techniques for added impact, he memorized the works of some of history's most inspiring orators.

Although he doubtless began with a degree of innate talent (his father, Randolph Churchill, was also an admired orator), Churchill clearly used extensive deliberate practice to build upon it. While this impressive resume and history solidified his place on the throne of oratorical excellence, it's important to note that he wasn't a "born speaker"—in fact, he made many mistakes. And he learned from them. If you want to produce a masterpiece, you need to accept that you'll make a lot of less remarkable work first.

Deliberate practice requires intense focus

"You seldom improve much without giving the task your full attention." —Karl Anders Ericsson

The deeper we focus during deliberate practice sessions, the more we get out of them. Intense focus allows us to increase skills and break through plateaus. Developing your attention span can have a huge impact on your life. When asked about his success, Charlie Munger once said, *"I succeeded because I have a long attention span."*

The authors of *The Game Before the Game* write, *"If you can pay attention for only five minutes in practice, then take a break every five minutes. If you can pay attention for only twenty balls, don't hit fifty. To be able to practice longer and maintain the quality of the practice, train yourself to pay attention for longer periods of time....Productive practice is about how present you can stay with your intention and is measured in the quality of the experience as opposed to the quantity of time used."*

A benefit of getting constant feedback is that it shows you what moves the needle towards improved performance and what is just running in place. Certain practice activities can feel good without having any impact. Top performers prioritize knowing what to prioritize. They always start with the most important thing because anything else is a distraction.

Intense focus is a multiplier of everything else. Keeping an eye on key metrics enables top performers to identify and systematically remove distractions from their lives. To be the best, you need to focus on both the micro and macro level. You need to pay full attention to what you're doing in the current practice sessions, and you need to know how it fits into

the bigger picture of your desired trajectory. Deliberate practice is part of the exploit phase of selecting opportunities.

As the authors of the *International Handbook of Research in Professional and Practice-Based Learning* write, “*Practicing the right things is at the core of the theory of deliberate practice.*”

How to implement this: Put the big rocks in first. You can do anything, but you can’t do everything. Figure out which practice activities have the biggest influence on your performance and plan to engage in those first before you even consider activities that offer marginal gains.

Deliberate practice leverages the spacing effect

One reason why consistent deliberate practice sessions over the course of years are more effective than longer sessions for a shorter period of time relates to the spacing effect. We can’t approach learning a skill through deliberate practice in the same way we quite likely approached studying for tests in school. If we better understand how our minds work, we can use them in the optimal way for learning. By leveraging the spacing effect, we can encode valuable knowledge related to our particular skill for life during practice sessions.

Memory mastery comes from repeated exposure to the same material. The spacing effect refers to how we are better able to recall information and concepts if we learn them in multiple sessions with increasingly large intervals between them. The most effective way to learn new information is through spaced repetition. It works for learning almost anything, and research has provided robust evidence of its efficacy for people of all ages—and even for animals.

Spaced repetition is also satisfying because it keeps us on the edge of our abilities (which, as we saw earlier, is a core element of deliberate practice.) Spaced sessions allow us to invest less total time to memorize than one single session, whereas we might get bored while going over the same material again and again in a single session. Of course, when we’re bored we pay less and less attention. The authors of *Focused Determination* put it this way:

There is also minimal variation in the way the material is presented to the brain when it is repeatedly visited over a short time. This tends to decrease our learning. In contrast, when repetition learning takes place over a longer period, it is more likely that the materials are presented differently. We have to retrieve the previously learned information from memory and hence reinforce it. All of this leads us to become more interested in the content and therefore more receptive to learning it.

We simply cannot practice something once and expect it to stick.

By engaging in deliberate practice on a regular basis, even if each practice session is short, we leverage the power of the spacing effect. Once we learn something through spaced repetition, it actually sticks with us. After a certain point, we may only need to revisit it every few years to keep our knowledge fresh. Even if we seem to forget something between repetitions, it later proves easier to relearn.

How to implement this: Forget about cramming. Each time you're learning a new component of a skill, make a schedule for when you'll review it. Typical systems involve going over information after an hour, then a day, then every other day, then weekly, then fortnightly, then monthly, then every six months, then yearly. Guess correctly and the information moves to the next level and is reviewed less often. Guess incorrectly and it moves down a level and is reviewed more often.

The history of deliberate practice

Karl Anders Ericsson: The expert on expertise

"Learning isn't a way of reaching one's potential but rather a way of developing it." —Karl Anders Ericsson, *Peak*

The concept of deliberate practice is attributed to Florida State University psychologist Karl Anders Ericsson, who along with his collaborators performed pioneering research in the field of expert performance. Ericsson spent decades seeking to answer the question of what it takes to become really good at something difficult. His research often focused on medicine, music, and sports.

Ericsson's interest in expert performance kicked off in the late 1970s, when he began working with psychologist Bill Chase at Carnegie Mellon University to study short-term memory. Together, they began a series of experiments to see how many random digits it's possible to memorize after hearing them once. Ericsson and Chase used an undergrad named Steve Faloon as their guinea pig. For a few hours each week, they read out numbers and Faloon repeated as many as he could recall.

Although the experiment might sound dull, they uncovered something intriguing. In a 1982 paper entitled "Exceptional Memory," Ericsson and Chase summarized their findings. Previously, researchers believed the average person could hold just seven random digits in their short-term memory. Yet with careful practice, Faloon began to remember more and more numbers. At his peak and after 200 hours of practice, he could recall 82 digits. To assess if this was a fluke, Ericsson tried the same with a friend, Dario Donatelli. Five years later, Donatelli could recall 113 digits. Both he and Faloon went far beyond what seemed to be an immovable ceiling on human performance and blew past existing world records.

The experience of seeing two people who started off with ordinary memories enhance their capabilities in such a drastic way inspired Ericsson to further study the effects of practice on skills. Could it be that extraordinary abilities came from extraordinary practice, not just innate ability?

Through his studies of expert performers in a range of fields, Ericsson concluded they practiced their skills in a fundamentally different way than amateur practitioners. Ericsson described this kind of practice as “deliberate” due to its methodical, hyper-conscious nature. He argued that experts become experts largely as a result of the way they practice. They may benefit from innate advantages, but their talents themselves are not innate.

Ericsson also believed that the standards in many additional fields could be improved far beyond their current level if practitioners employed the principles of deliberate practice. Indeed, many fields have seen remarkable increases in their standards for high performance over time. Today, high-schoolers manage athletic feats that were once Olympic level and children play music once considered world-class. This is possible because of better training and knowledge of what it takes to be the best. The more we improve how we train, the more we expand our range of possible performance.

In 2016, Ericsson published *Peak: Secrets from the New Science of Expertise*, a popular science book condensing his learnings from thirty years of research. He also co-edited the 2006 *Cambridge Handbook of Expertise and Expert Performance*.

Malcolm Gladwell: The 10,000 hour rule

The widespread awareness of Ericsson’s work outside the scientific community is in part a result of Malcolm Gladwell’s 2008 book, *Outliers: The Story of Success*. In the book, Gladwell attributed unusual success in different fields to a mixture of lucky factors (such as when or where a person was born) and around 10,000 hours of practice. He based this figure on research, including Ericsson’s, that suggested top performers tended to have put in about that amount of time before reaching peak performance.

Gladwell showed how the success of Bill Gates, the Beatles, and other outstanding performers is not so much to do with what they are like but rather where they come from. “*The people who stand before kings may look like they did it all by themselves,*” Gladwell writes. “*But in fact they are invariably the beneficiaries of hidden advantages and extraordinary opportunities and cultural legacies that allow them to learn and work hard and make sense of the world in ways others cannot.*”

The so-called “10,000 hours rule” caught on. It’s a catchy idea, and many people took it to mean that anyone can master anything if they just put the time in. Ericsson himself disputed Gladwell’s representations of his research, which led to the widespread belief that

the time someone spends practicing predicts their success, without emphasizing the quality of their practice.

Although the backlash against Gladwell's calculation has arguably been exaggerated, it's important to stress that research into deliberate practice emphasizes quality of practice, not quantity. It's all too possible to spend 10,000 hours engaging in a skill without serious improvements. For example, most of us spend hours per day typing, yet we don't see continuous improvements in speed and quality because we're not using deliberate practice.

The useful takeaway from the "10,000 hours rule" is simply that it takes a lot of work to become the best. There's no magic number of practice sessions, and everyone's path will look different. Just because successful people in a given field have spent around 10,000 hours practicing their key skill, that doesn't mean every person who practices that skill for 10,000 hours will become successful.

The limitations and downsides of deliberate practice

Part of us wants to believe expert performance is something innate and magical so we can recuse ourselves from hard work. The other part of us wants to believe that it's something earned through blood, sweat, and tears—that we too could achieve amazing performance, if only we could devote ourselves to something.

Deliberate practice, in reality, is far more complex and nuanced than many people would have you believe. It's not a panacea, and it won't solve all of your work- and art-related problems. Let's take a look at some of the limitations of deliberate practice.

First of all, deliberate practice is a necessary but insufficient part of becoming a world-class performer. You can't rise to the top without it. But it's not enough on its own to be the absolute best in any field. Once you reach higher echelons for any skill, everyone is engaging in a lot of deliberate practice.

If you're aiming at expertise or just really good performance, deliberate practice will most likely get you there. But the higher you rise, the more luck and randomness end up mattering. However much you engage in deliberate practice, you can't control the chance events (good or bad) that dictate a great deal of life.

When we look at the lives of top performers, they often benefited from specific backgrounds or opportunities, in addition to engaging in deliberate practice. For example, if you're trying to become a champion chess player, it's a big boost if your mother was a champion chess player. Not only will you have potential genetic advantages, you'll have

also likely grown up hearing about chess, been encouraged to practice it from a young age, and have someone to turn to for advice.

Seeing as it takes years of consistent deliberate practice to master a skill, people who begin early in life have an advantage over those who start later on. That doesn't mean you can't become exceptional at something you discover well into adulthood (just look at [Julia Child](#) or check out the book [Guitar Zero](#)). But it does mean that people who begin deliberate practice as kids are more likely to enjoy the success that makes it possible to keep committing to it. If you're trying to master a skill while also having to work an unrelated job, care for your family, and deal with the other myriad responsibilities of adult life, you likely will have less room for it than a ten-year-old.

People who discover they want to master a skill or are encouraged to do so by others early in life have an advantage. Once the opportunity for practice is in place, the prospects of high achievement take off. And if practice is denied or diminished, no amount of talent is going to get you there.

In addition to lucky circumstances, high performers benefit from a combination of deliberate practice and innate talents or physical advantages. However much you practice, certain physical limitations are insurmountable. For example, if you're 165 centimeters tall, you're unlikely to become a professional basketball player. There are some physical abilities, such as particular kinds of flexibility, that can only be developed at a young age when a person's skeletal structure is still forming. It's important to be realistic about your starting point and be aware of any limitations. But that doesn't mean you can't develop workarounds or even use them to your advantage.

Another downside of deliberate practice is that the level of focus it requires can mean practitioners miss out on other parts of life. Top performers often devote almost every waking hour to practice, recuperation from practice, and support activities. For example, a professional dancer might spend several hours a day on deliberate practice with all of the remaining hours going toward sleep, low-impact exercise, stretching, preparing nutritious food, icing his feet, and so on. There is enormous satisfaction in the flow states produced by deliberate practice, but practitioners can absolutely miss out on other sources of happiness, such as spending time with friends.

Deliberate practice is part of the exploit phase of new opportunities. Yet sometimes we can end up having too much [grit](#). We can keep persevering with the skill we're practicing right now, remaining overly passionate, past the point where it serves us. We can wear ourselves out or get hurt or fail to realize when it's no longer worth practicing a skill. For example, a new technology might mean our skill is no longer valuable. If we keep on

deliberate practicing due to sunk costs, we'll be unlikely to see many long-term benefits from it. A crucial skill in life is knowing when to pivot. Focusing too much on our goals can blind us to risks.

In some fields, expertise is hard to quantify or measure, which makes it less clear how to structure practice. There may be no single target to hit or universal rule for what improves performance.

A final limitation to keep in mind is that, as Ericsson explained, "*the cognitive and physical changes caused by training require upkeep. Stop training and they go away.*" If someone can't practice for a period of time, such as due to an injury or having a child, they're likely to see the skills they developed through deliberate practice deteriorate.

Summary

Deliberate practice isn't everything, but if you want to keep improving at a skill or overcome a plateau, you'll benefit from incorporating the principles mentioned in this article. To recap:

- Deliberate practice means practicing with a clear awareness of the specific components of a skill we're aiming to improve and exactly how to improve them.
- The more we engage in deliberate practice, the greater our capabilities become.
- Our minds and bodies are far more malleable than we usually realize.
- Deliberate practice is structured and methodical.
- Deliberate practice is challenging because it involves constantly pushing yourself out of your comfort zone.
- Deliberate practice requires constant feedback and measurement of informative metrics—not vanity metrics.
- Deliberate practice works best with the help of a teacher or coach.
- Continuing deliberate practice requires a great deal of intrinsic motivation.
- Deliberate practice requires constant, intense focus.
- Deliberate practice leverages the spacing effect—meaning a consistent commitment over time is crucial.
- If you're content with your current level of skill or just doing something for fun, you don't necessarily need to engage in deliberate practice
- Deliberate practice is best suited to pursuits where you're actively aiming for a high level of performance or to break beyond some kind of supposed limit.

1. Jeffrey Pfeffer: Why Performance Won't Get You Promoted

If you're going to play the game you should at least educate yourself on the unwritten rules. If you don't, you'll always be at a disadvantage.

In an NPR interview (audio below), Stanford business professor Jeffrey Pfeffer highlights why performance won't get you promoted and why power corrupts.

Here are my notes on the audio interview:

1. Performance is elusive and thus can be shaped and managed;
2. You can do your job too well;
3. The world doesn't work the way you want it to – the way to change it is to go out and make something happen;
4. Power corrupts — when you attain power you don't think you have to follow the rules anymore;
5. When you're in a position of power everyone is trying to curry your favor and you end up surrounded by sycophants;
6. Power can be converted into money;
7. Power gives you control over your work (time and pace);
8. You need power to get things done;
9. The more powerful you are the less people will be willing to forgive you;
10. Influence is power in action; and
11. You can have power or autonomy but not both.

Some of you might be skeptical of Pfeffer's tactics; but he points out, that if the ends don't justify the means then what does?

My favorite part of the interview was the quote from a newsman saying: if you don't like today's news, go out and make some of your own.

According to Pfeffer's book Power: Why Some People Have It And Others Don't, there are seven personal qualities that help to build power: ambition, energy, focus, self-knowledge, confidence, empathy with others, and capacity to tolerate conflict. Intelligence and high performance didn't make the cut.

The book recommends a few simple steps you can take to increase your power:

1. Be visible;
2. Emphasize the aspects you're good at;
3. Make those in power feel good about themselves;
4. If you must point out a mistake by someone in power, blame the situation or others; and
5. Shower those above with flattery.

4. The Myth of Multitasking: Why the Key to Better Work is Developing Forgotten Skills

Of course you can do more than one thing at once. The catch is you can't do more more than one thing at once that requires concentration. You can walk and chew gum, but you can't write an email and a report at the same time.

When you're doing two things at once that are cognitively demanding, what you're really doing is switching back and forth very quickly from one task to another.

The brain is a pretty smooth operator when it knows what direction to head. Transitioning from one task to another, however, dramatically reduces its horsepower.

There is a mental cost—called a switching cost—to all of this multitasking. But that's not all it makes deep thinking impossible.

Steven Yantis, a professor of psychological and brain sciences at Johns Hopkins, says:

In addition to the switch cost, each time you switch away from a task and back again, you have to recall where you were in that task, what you were thinking about. If the tasks are complex, you may well forget some aspect of what you were thinking about before you switched away, which may require you to revisit some aspect of the task you had already solved (for example, you may have to re-read the last paragraph you'd been reading).

Deep thinking about a complex topic can become nearly impossible.

Multitasking ensures the brain is operating sub-optimally.

When you try to do two or more cognitively demanding things at once, it's as if you have a 1000 h.p. motor (your brain) but your throttling only gets you 100 h.p. of output.

There is a difference between the appearance of being busy—busywork—and actually moving the needle. Attempting to do more things may signal to others how busy you are, but if you care about actual results, you need to do fewer things better.

Our most valuable mental habits—things like deep and focused thought—must be learned through concentrated practice. This is a skill we're starting to lose as more and more of our time gets fragmented away into small and smaller increments thanks to screens. Nicolas Carr, author of The Shallows: What the Internet Is Doing To Our Brain, comments on his blog:

Our most valuable mental habits – the habits of deep and focused thought – must be learned, and the way we learn them is by practicing them, regularly and attentively. And that's what our continuously connected, constantly distracted lives are stealing from us: the encouragement and the opportunity to practice reflection, introspection, and other contemplative modes of thought. Even formal research is increasingly taking the form of "power browsing," according to a 2008 University College London study, rather than attentive and thorough study.

Patricia Greenfield, a professor of developmental psychology at UCLA, warns that our growing use of screens appears to weaken our "higher-order cognitive processes," including "abstract vocabulary, mindfulness, reflection, inductive problem solving, critical thinking, and imagination."

Busywork leads to overwork and sub-optimal outputs. Busywork is a psychological signal to others (and ourselves) that we're needed. That we're important. After-all, look how busy I am. This delusion is the reason we take on so many things and fail to say no. This delusion keeps us so busy that we're not learning new things or even getting better at what we already do. This delusion inhibits us from deriving meaning in our work and our lives.

This delusion keeps us from understanding how the world works and adapting to the changing reality.

The world is a competitive place. That means we have to learn how to do difficult things—things that other people value, things other people can't do. This isn't as easy as it sounds.

What we really need to develop is not so much the specific traits that will be valued as much as a system to constantly reinvent ourselves and adapt.

This is the hard part and in an odd way, we need to go backwards to go forward. We need to develop skills we've once had and lost: The ability to read better, the ability to make better decisions, the ability to focus, and strategies to make sure we're not consumed by busywork. These are the skills that will enable us to have quality ideas that other people don't have. These are the foundational skills that underpin adaptability.

5. The Myth of Multitasking: Why the Key to Better Work is Developing Forgotten Skills

Of course you can do more than one thing at once. The catch is you can't do more more than one thing at once that requires concentration. You can walk and chew gum, but you can't write an email and a report at the same time.

When you're doing two things at once that are cognitively demanding, what you're really doing is switching back and forth very quickly from one task to another.

The brain is a pretty smooth operator when it knows what direction to head. Transitioning from one task to another, however, dramatically reduces its horsepower.

These are the skills that will enable us to have quality ideas that other people don't have. These are the foundational skills that underpin adaptability.

6. Why is it so Hard to Kill a Cockroach with your Shoe?

The Cockroach Papers by Richard Schwied is an interesting book if you are looking to learn more about biology or evolution. Cockroaches are built for survival no matter what the world throws at them. Their ability to adapt is just amazing.

Here are some of my notes from the book.

Food and Water

German cockroaches, *Blattella germanica*, the most common domestic roach in the United States, have been observed to live 45 days without food, and more than two weeks with neither food nor water.

Cockroaches will eat almost anything including glue, feces, hair, decayed leaves, paper, leather, banana skins, other cockroaches, and dead or alive humans. They will not, however, eat cucumbers. They are particularly fond of dried milk around a baby's mouth. The roaches are not confined to any particular environment and live in a tremendous variety of places, from underneath woodpiles in Alaska to high in the jungle canopy in the tropics of Costa Rica. They are even found in the caves of Borneo and under the thorn bushes in arid stretches of Kenya. Wherever they live, they are masters at surviving. They are, Schwied writes, "undeniably one of the pinnacles of evolution on this planet."

Why is it so hard to kill a cockroach with your shoe?

Schweid observes that "when a cockroach feels a breeze stirring the hairs on its cerci, it does not wait around to see what is going to happen next, but leaves off whatever it is doing and goes immediately into escape mode in something remarkably close to instantaneous fashion." Studies show that a cockroach can respond in about 1/20th of a second, so "by the time a light comes on and human sight can register it, much less react by reaching for and hoisting something with which to squash it, a roach is already locomoting towards safety."

Blood

Cockroach blood is a pigments, clear substance circulating through the interior of its body, and what usually spurts out of a roach when its hard, , outer shell—its exoskeleton—is penetrated or squashed is a cream-colored substance resembling nothing so much as pus or smegma.

Brains

Cockroaches have two brains—one inside their skulls, and a second, more primitive brain that is back near their abdomen.

Copulation

Schweid says "Pheromones, chemical signals of sexual readiness, operate between a male and female cockroach to initiate courtship and copulation. A sexually receptive female assumes a posture with her abdomen lowered and her wings raised and gives off a pheromone that attracts males." If he finds a virgin female, a male cockroach after some antenna rubbing foreplay will turn away from the female and raise his wings, "an invitation to her to mount." Copulation frequently lasts an hour. After sex, female cockroaches store the sperm and use them as needed. The sperm may last her a lifetime.

"The evolutionary strategy employed by cockroaches to reproduce is considerably more efficient than that employed by humans." Oddly, there are certain species of cockroaches that can, at least for a generation or two, reproduce without any sperm. Schweid says "the females unfertilized eggs will develop and hatch—always producing new females."

Partying

Betty Faber, the former staff entomologist for the New York Natural History Museum, says "Females go to bed—by which I mean disappear back to the harborage—at night earlier than males."

Socialness

Schweid writes, "cockroaches, while not social insects in the entomological sense of bees

or ants with clearly assigned tasks that benefit the whole community, do clearly take pleasure in the company of other roaches, and the aggression pheromones draw them together, eliciting their effects regardless of the sex or age.” Cockroaches reared singly develop more slowly and take longer between molts than do those reared in a group. Although those groups can be too big “just as development is delayed in young cockroaches if they are isolated, over-crowding also extends the time between molts. So there is yet another kind of pheromone, called a “dispersal pheromone,” and it serves as the chemical signal that it is time to look for a new, slightly roomier harborage. This chemical is found in the insects’ saliva, and has just the opposite effect of the aggression attractant, in that it repulses cockroaches and causes them to look elsewhere for harborage.”

Radiation

In case you’re thinking we can just nuke the little critters you should know that cockroaches survived the atomic bombs test blast at Bikini. “There is such a thing as a lethal dose of radiation for a cockroach, but it is a lot higher than our own.”

Predators

“While few humans may eat them, the roach has both external and internal predators and parasites. There are centipedes that have a primary diet of cockroaches. Mantises, ants, and scorpions will eat them, as will a variety of larger animals including toads, frogs, possums, hedgehogs, armadillos, mongooses, monkeys, lizards, spiders, mice, cats, and birds”

Sleeping

Roaches are nocturnal and pass their days sleeping.

Male aggression

“Cockroaches, like so many other species including our own, have male aggression rituals. They have their own inventory of aggressive behaviors, a scale of conflict that begins with threatening postures. Beyond that they graduate to antenna lashing—a form of which is also present in male/female encounters to determine if a female is sexually receptive—and biting. Sex and territory seem to be the primary motivations for fighting between male cockroaches: These clashes never end in death, but always in the retreat of one fighter.”

Trapping a cockroach

“Stale white bread moistened with warm, slightly soured beer” is the most reliable and effective. “This is typically placed at the bottom of a small jar—a Gerber’s baby food jar, say—around the interior rim of which a petroleum jelly like Vaseline has been applied. The cockroach can climb in from the outside but can’t climb back out.”

What should you do if you get a cockroach stuck in your ear?

“It is, according to all accounts, painful and horrifying, although a little mineral oil or lidocaine sprayed into the ear is usually enough to dislodge the intruder.”

Exterminators

Exterminators primarily employ two methods to kill the cockroach: gas and gel. The gel is way more effective but many still rely on the spray. Why? “The major problem that exterminators have with the gel is that it has no immediate knockdown effect.”

John Wickham, an English pest control consultant defined knockdown as: “The inability of the insect to move in a sufficiently coordinated manner to right itself and progress normally.” When a roach eats gel bait—the safer of the two methods—it heads home before the active poison kills it.

“Customers who are paying \$75 an hour like to see these roaches struggling to get up, in agony and convulsions, and the sprays, with substantial knockdown effect, provide them that gratifying visual reassurance that the problem is being solved and that they are getting their money’s worth.

It’s unlikely this poison will have much long term impact. “Almost as soon as an effective poison goes into widespread use, cockroaches begin to develop Resistance. And,

typically, the most efficacious products developed, those that do the best job, turn out to be more detrimental to our own health than are the roaches.”

7. Top Athletes And Singers Have Coaches. Should You?

Getting better at something you're decent at, isn't as easy as it sounds. Consider driving. A skill you likely learned as a teenager. Within a few hundred hours under the wheel, you went from a petrified know nothing to a competent and predictable driver.

Let's say you're mid-30s now and you want to get better at driving. How would you do it? The easiest way is to hire a back seat driver — someone to tell you that you're taking the turns too sharply, or not coming to a complete stop. Basically, their job would be to point out all the little things you do that keep you from getting better.

Isn't not hard to find this person. The hard part is putting your pride and reputation on the line.

We can't do this for everything but we can do it for some things. The things that matter the most.

With that in mind, here is a wonderful essay by Atul Gawande in the New Yorker on whether we need a personal coach.

...I'd paid to have a kid just out of college look at my serve. So why did I find it inconceivable to pay someone to come into my operating room and coach me on my surgical technique?

...Elite performers, researchers say, must engage in "deliberate practice"—sustained, mindful efforts to develop the full range of abilities that success requires. You have to work at what you're not good at. In theory, people can do this themselves. But most people do not know where to start or how to proceed. Expertise, as the formula goes, requires going from unconscious incompetence to conscious incompetence to conscious competence and finally to unconscious competence. The coach provides the outside eyes and ears, and makes you aware of where you're falling short.

...Osteen watched, silent and blank-faced the entire time, taking notes. My cheeks burned; I was mortified. I wished I'd never asked him along. I tried to be rational about the situation—the patient did fine. But I had let Osteen see my judgment fail; I'd let him see that I may not be who I want to be.

This is why it will never be easy to submit to coaching, especially for those who are well along in their career. I'm ostensibly an expert. I'd finished long ago with the days of being tested and observed. I am supposed to be past needing such things. Why should I expose myself to scrutiny and fault-finding?

If you're interested in learning more about effective coaching, check out Barbara Lourie Sand's book "Teaching Genius," which describes the methods of the legendary Juilliard violin instructor Dorothy DeLay. DeLay trained an amazing roster of late-twentieth-century virtuosos, including Itzhak Perlman, Nigel Kennedy, Midori, and Sarah Chang.

8. Learning Effectively From Experience: Distinguishing High from Low Performers

High performers learn from both success and failure making small adjustments.

Conversely, low performers learned more from success.

Learning effectively from experience is a daunting task for any organism. For every good or bad outcome, there are an immense number of potential causes and associations to be considered. For many decisions, it can be nearly impossible to pick out the few relevant factors from the many irrelevant factors, even with extensive experience. A major stumbling block for learning in these multi-dimensional environments is the tendency to form spurious beliefs: i.e., to attribute a causal role to factors that have no actual bearing on the outcome.

The formation of spurious beliefs is universal, from Skinner's observations of superstitious pigeons [1] to an athlete's belief in a lucky hat. In some situations, these beliefs are essentially harmless; by-products of learning mechanisms, but in other settings their impact can be severe. For example, spurious associations can have literal life-or-death consequences when they affect the complex decisions made by physicians. These expert decision-makers must extract and distill relevant features from a myriad of tests, symptoms, and personal histories, and employ these features to make critical medical decisions. Consequently, it is important to understand how spurious associations form and how they can bias subsequent decisions.

Spurious learning and false belief formation happens when the dorsolateral prefrontal cortex fails to distinguish correctly between important and unimportant associations.

The authors conclude:

High performers learned from both successes and failures, and made smaller rule adjustments after feedback. Conversely, low performers learned disproportionately from successes, and made larger rule adjustments ...

Taken together, the behavioral and neuroimaging results suggest that success-chasing and confirmation bias may underlie the relative pervasiveness of premature, asymmetric learning and the resultant poor performance of the majority of physician subjects in the present study. The general human bias towards confirmation over disconfirmation in hypothesis-testing has been extensively documented in a variety of non-medical contexts, such as the Wason Card Task. Conversely, the necessity for disconfirmation learning in empirical investigations is a key principle identified by the philosopher of science, Karl Popper [28]. Conceivably, providing medical professionals with formal training in disconfirmation learning could improve their ability to learn effectively from clinical experience in real-world settings. Exploring this possibility would be an important area for future research.

In conclusion, the results of this study show distinct patterns of learning, both behaviorally and neurally, between effective and ineffective learners among physicians making decisions in a medically framed learning task. The tendency to chase successes and ignore failures provides a simple computational model of how spurious beliefs might be formed, and how different individuals seeing similar data might learn very different sets of associations. The neural differences observed could conceivably be developed into useful biomarkers for essential differences in individual learning styles. These may in turn prove useful in identifying those individuals who can resist the impulse to chase successes, and hence learn most effectively from experience. Finally, we note that although this study focused upon the specific case of medical decision-making, the findings may be also be relevant to many other fields in which experts must make high-stakes decisions by drawing upon personal experience.

Abstract:

Accurate associative learning is often hindered by confirmation bias and success-chasing, which together can conspire to produce or solidify false beliefs in the decision-maker. We performed functional magnetic resonance imaging in 35 experienced physicians, while they learned to choose between two treatments in a series of virtual patient encounters. We estimated a learning model for each subject based on their observed behavior and this model divided clearly into high performers and low performers. The high performers showed small, but equal learning rates for both successes (positive outcomes) and failures (no response to the drug). In contrast, low performers showed very large and asymmetric learning rates, learning significantly more from successes than failures; a tendency that led to sub-optimal treatment choices. Consistently with these behavioral findings, high performers showed larger, more sustained BOLD responses to failed vs. successful outcomes in the dorsolateral prefrontal cortex and inferior parietal lobule while low performers displayed the opposite response profile. Furthermore, participants' learning asymmetry correlated with anticipatory activation in the nucleus accumbens at trial onset, well before outcome presentation. Subjects with anticipatory activation in the nucleus accumbens showed more success-chasing during learning. These results suggest that high performers' brains achieve better outcomes by attending to informative failures during training, rather than chasing the reward value of successes. The differential brain activations between high and low performers could potentially be developed into biomarkers to identify efficient learners on novel decision tasks, in medical or other contexts.

9. The Science Of Habit Formation And Change

From The Power of Habit: Why We Do What We Do in Life and Business

Chunking — The Root of Habits

The process—in which the brain converts a sequence of actions into an automatic routine—is known as ‘chunking,’ and it’s at the root of how habits form.

Why do Habits Emerge?

Habits, scientists say, emerge because the brain is constantly looking for ways to save effort. Left to its own devices, the brain will try to make almost any routine into a habit, because habits allow our minds to ramp down more often. This effort-saving instinct is a huge advantage. An efficient brain requires less room, which makes for a smaller head, which makes childbirth easier and therefore causes fewer infant and mother deaths. An efficient brain also allows us to stop thinking constantly about basic behaviors ...

The Three Step Loop of Habit Formation:

This process within our brains is a three-step loop. First, there is a cue, a trigger that tells your brain to go into automatic mode and which habit to use. Then there is the routine, which can be physical or mental or emotional. Finally, there is a reward, which helps your brain figure out if this particular loop is worth remembering for the future: Over time, this loop—cue, routine, reward; cue, routine, reward—becomes more and more automatic. The cue and reward become intertwined until a powerful sense of anticipation and craving emerges. Eventually... a habit is born.

Does the Brain Stop Working?

When a habit emerges, the brain stops fully participating in decision making. It stops working so hard, or diverts focus to other tasks. So unless you deliberately fight a habit—unless you find new routines—the pattern will unfold automatically.

How To Change A Habit:

We know that a habit cannot be eradicated—it must, instead, be replaced. And we know that habits are most malleable when the Golden Rule of habit change is applied: If we keep the same cue and the same reward, a new routine can be inserted. But that’s not enough. For a habit to stay changed, people must believe change is possible. And most often, that belief only emerges with the help of a group.

Does a Habit Disappear?

Habits never really disappear. They’re encoded into the structures of our brain, and that’s a huge advantage for us, because it would be awful if we had to relearn how to drive after every vacation. The problem is that your brain can’t tell the difference between bad and good habits, and so if you have a bad one, it’s always lurking there, waiting for the right cues and rewards.”

10. What is Deliberate Practice?

Deliberate practice is a method for improving your performance at anything, based on constant feedback and working at the edge of your abilities. Elite people in every field use it to build up their expertise. Let's take a look at exactly what deliberate practice is, how to do it, and why it works.

You've probably been doing your job for a while. If you're like most people, your performance has plateaued. Simply put, you've stopped getting better at what you do. This is because you don't use deliberate practice to your advantage.

Despite repetition, most people fail to become experts at what they do. It doesn't matter how many years they spend they stop getting better.

Experience does not equate to expertise.

In Geoff Colvin's book Talent Is Overrated he writes:

In field after field, when it comes to centrally important skills—stockbrokers recommending stocks, parole officers predicting recidivism, college admissions officials judging applicants—people with lots of experience were no better at their jobs than those with less experience.

Society has always recognized extraordinary individuals whose performance is truly superior. If I were to ask you why some people excel and others don't, you'd probably say talent and effort. These responses are misleading.

Conveniently, claiming that talent is the basis for success means we can absolve ourselves of our own performance (or, as the case may be, lack thereof). The talent argument, despite its popularity, is wrong. Yet research tells a very different story on how people become experts (for a more detailed argument read Talent Is Overrated, the source of most of the quotes in this article).

Deliberate Practice

Research concludes that we need *deliberate* practice to improve performance.

Unfortunately, deliberate practice isn't something that most of us understand, let alone engage in on a daily basis. This helps explain why we can work at something for decades without really improving our performance.

Deliberate practice is hard. It hurts. But it works. More of it equals better performance and tons of it equals great performance.

Most of what we consider practice is really just playing around — we're in our comfort zone.

When you venture off to the golf range to hit a bucket of balls what you're really doing is having fun. You're not getting better. Understanding the difference between fun and deliberate practice unlocks the key to improving performance.

Deliberate practice is characterized by several elements, each worth examining. It is activity designed specifically to improve performance, often with a teacher's help; it can be repeated a lot; feedback on results is continuously available; it's highly demanding mentally, whether the activity is purely intellectual, such as chess or business-related activities, or heavily physical, such as sports; and it isn't much fun.

Let's take a look at each of those to better understand what's meant.

Designed to Improve Performance

The word designed is key. While enjoyable, practice lacking design is play and doesn't offer improvement.

"In some fields, especially intellectual ones such as the arts, sciences, and business, people may eventually become skilled enough to design their own practice. But anyone who thinks they've outgrown the benefits of a teacher's help should at least question that view. There's a reason why the world's best golfers still go to teachers."

But it's more than just the teachers' knowledge that helps — it's their ability to see you in ways you can't see yourself.

“A chess teacher is looking at the same boards as the student but can see that the student is consistently overlooking an important threat. A business coach is looking at the same situations as a manager but can see, for example, that the manager systematically fails to communicate his intentions clearly.”

In theory, with the right motivations and some expertise, you can design a practice yourself. It's likely, however, that you wouldn't know where to start or how to structure activities.

*Expertise, as the formula goes, requires going from unconscious incompetence to conscious incompetence to conscious competence and finally to unconscious competence. **

Teachers, or coaches, see what you miss and make you aware of where you're falling short.

With or without a teacher, great performers deconstruct elements of what they do into chunks they can practice. They get better at that aspect and move on to the next.

Noel Tichy, professor at the University of Michigan business school and the former chief of General Electric's famous management development center at Crotonville, puts the concept of practice into three zones: the comfort zone, the learning zone, and the panic zone.

Most of the time we're practicing we're really doing activities in our comfort zone. This doesn't help us improve because we can already do these activities easily. On the other hand, operating in the panic zone leaves us paralyzed as the activities are too difficult and we don't know where to start. The only way to make progress is to operate in the learning zone, which are those activities that are just out of reach.

Consider a chess tournament:

*Skill improvement is likely to be minimized when facing substantially inferior opponents, because such opponents will not challenge one to exert maximal or even near-maximal effort when making tactical decisions, and problems or weaknesses in one's play are unlikely to be exploited. At the same time, the opportunity for learning is also attenuated during matches against much strong opponents, because no amount of effort or concentration is likely to result in a positive outcome.**

Repeat

Repetition inside the comfort zone does not equal practice. Deliberate practice requires that you should be operating in the learning zone and you should be repeating the activity a lot with feedback.

*Let us briefly illustrate the difference between work and deliberate practice. During a three hour baseball game, a batter may only get 5-15 pitches (perhaps one or two relevant to a particular weakness), whereas during optimal practice of the same duration, a batter working with a dedicated pitcher has several hundred batting opportunities, where this weakness can be systematically exploited. **

It's no coincidence that Ted Williams, baseball's greatest hitter, would literally practice hitting until his hands bled.

Feedback on results is continuously available

Practicing something without knowing whether you are getting better is pointless. Yet that is what most of us do everyday without thinking.

“You can work on technique all you like, but if you can't see the effects, two things will happen: You won't get any better, and you'll stop caring.”

Feedback gets a little tricky when someone must subjectively interpret the results. While you don't need a coach, this can be an area they add value.

“These are the situations in which a teacher, coach, or mentor is vital for providing crucial feedback.”

Mentally Demanding

Doing things we know how to do is fun and does not require a lot of effort. Deliberate practice, however, is not fun. Breaking down a task you wish to master into its constituent parts and then working on those areas systematically requires a lot of effort.

“The work is so great that it seems no one can sustain it for very long. A finding that is remarkably consistent across disciplines is that four or five hours a day seems to be the upper limit of deliberate practice, and this is frequently accomplished in sessions lasting no more than an hour to ninety minutes.”

Ben Franklin, an interesting example

Ben Franklin intuitively grasped the concept of deliberate practice. As a teenager Ben received a letter from his father saying his writing was inferior: “in elegance of expression, in method and in perspicuity, of which he convinced me by several instances,” as Franklin recalled.

“Ben responded to his father’s observations in several ways. First, he found examples of prose clearly superior to anything he could produce, a bound volume of the Spectator, the great English periodical written by Joseph Addison and Richard Steele. Any of us might have done something similar. But Franklin then embarked on a remarkable program that few of us would have ever thought of.

It began with his reading a Spectator article and marking brief notes on the meaning of each sentence; a few days later he would take up the notes and try to express the meaning of each sentence in his own words. When done, he compared his essay with the original, “discovered some of my faults, and corrected them.

One of the faults he noticed was his poor vocabulary. What could he do about that? He realized that writing poetry required an extensive “stock of words” because he might need to express any given meaning in many different ways depending on the demands of rhyme or meter. So he would rewrite Spectator essays in verse. ...

Franklin realized also that a key element of a good essay is its organization, so he developed a method to work on that. He would again make short notes on each sentence in an essay, but would write each note on a separate slip of paper. He would then mix up the notes and set them aside for weeks, until he had forgotten the essay. At that point he would try to put the notes in their correct order, attempt to write the essay, and then compare it with the original; again, he “discovered many faults and amended them.”

Even without a teacher, Ben Franklin grasped deliberate practice.

The Role of Solitude

In her book, Quiet: The Power of Introverts in a World That Can’t Stop Talking, Susan Cain writes:

Deliberate Practice is best conducted alone for several reasons. It takes intense concentration, and other people can be distracting. It requires deep motivation, often self-generated. But most important, it involves working on the task that’s most challenging to you personally. Only when you’re alone, Ericsson told me, can you “go directly to the part that’s challenging to you. If you want to improve what you’re doing, you have to be the one who generates the move. Imagine a group class—you’re the one generating the move only a small percentage of the time.”

11. The clarity paradox — why success is a catalyst for failure

Greg McKeown explains why successful people don't become very successful in The Disciplined Pursuit of Less.

Why don't successful people and organizations automatically become very successful?

One important explanation is due to what I call "the clarity paradox," which can be summed up in four predictable phases:

Phase 1: When we really have clarity of purpose, it leads to success.

Phase 2: When we have success, it leads to more options and opportunities.

Phase 3: When we have increased options and opportunities, it leads to diffused efforts.

Phase 4: Diffused efforts undermine the very clarity that led to our success in the first place.

12. “That’s as far as they go. They can’t take it any further. And why not? Because they won’t put in the effort”

A brilliant passage from Haruki Murakami’s Norwegian Wood on talent.

There just happen to be people like that. They’re blessed with this marvelous talent, but they can’t make the effort to systematize it. They end up squandering it in little bits and pieces. I’ve seen my share of people like that. At first you think they’re amazing. Like, they can sight-read some terrifically difficult piece and do a damn good job playing it all the way through. You see them do it, and you’re overwhelmed. You think, ‘I could never do that in a million years.’ But that’s as far as they go. They can’t take it any further. And why not? Because they won’t put in the effort. Because they haven’t had the discipline pounded into them. They’ve been spoiled. They have just enough talent so they’ve been able to play things well without any effort and they’ve had people telling them how great they are from the time they’re little, so hard work looks stupid to them. They’ll take some piece another kid has to work on for three weeks and polish it off in half the time, so the teacher figures they’ve put enough into it and lets them go to the next thing. And they do that in half the time and go on to the next piece. They never find out what it means to be hammered by the teacher; they lose out on a certain element required for character building. It’s a tragedy.

This sounds an awful lot like Carol Dweck:

In her influential research, (Carol) Dweck distinguishes between people with a fixed mindset — they tend to agree with statements such as “You have a certain amount of intelligence and cannot do much to change it” — and those with a growth mindset, who believe that we can get better at almost anything, provided we invest the necessary time and energy. While people with a fixed mindset see mistakes as a dismal failure — a sign that we aren’t talented enough for the task in question — those with a growth mindset see mistakes as an essential precursor of knowledge, the engine of education.

And this bit from The Art of Learning: An Inner Journey to Optimal Performance:

Children who are “entity theorists” ... are prone to use language like ‘I am smart at this.’ And to attribute their success or failure to an ingrained and unalterable level of ability. They see their overall intelligence or skill level at a certain discipline to be a fixed entity, a thing that cannot evolve. Incremental theorists, who have picked up a different modality of learning, are more prone to describe their results with sentences like ‘I got it because I worked very hard at it’ or ‘I should have tried harder.’ A child with a learning theory of intelligence tends to sense that with hard work, difficult material can be grasped- step-by-step, incrementally, the novice can become the master.

This is the path of amateurs:

By nature, we humans shrink from anything that seems possibly painful or overtly difficult. We bring this natural tendency to our practice of any skill. Once we grow adept at some aspect of this skill, generally one that comes more easily to us, we prefer to practice this element over and over. Our skill becomes lopsided as we avoid our weaknesses. Knowing that in our practice we can let down our guard, since we are not being watched or under pressure to perform, we bring to this a kind of dispersed attention. We tend to also be quite conventional in our practice routines. We generally follow what others have done, performing the accepted exercises for these skills.

This is the path of amateurs. To attain mastery, you must adopt what we shall call Resistance Practice. The principle is simple—you go in the opposite direction of all of your natural tendencies when it comes to practice.

If you want to get better at anything, you need to practice.

13. The 8 Causes of Plateaus

Have you ever found yourself trying really hard on something you care about?

Maybe you're learning how to play the piano. But the more effort you put in, the less you seem to get out of it. You've plateaued, according to Bob Sullivan and Hugh Thompson.

"Trying harder," they write in The Plateau Effect: Getting from Stuck to Success, "is a failed, frustrating strategy." ... "We're here to tell you that every day, the universe is conspiring against people who think that more is the answer."

If doubling down on hard work isn't the solution what is?

Thompson and Sullivan argue there are 8 reasons we plateau, and they, of course, offer tips to overcome them all.

Here is the cheat sheet.

When you were (supposed to be) reading the Classics in high school, Cliff Notes were bad. In fact, Bob recently met an employee of a company that makes animated version of CliffNotes – which apparently aren't Cliff-y enough for today's students.

But when you're trying to improve your life and move past those plateaus that hold you back, CliffNotes are great. They are efficient; they give you more results for less work – two of our main goals for teaching people about the Plateau Effect. So, here we give you our version of CliffNotes. If you're stuck, one of these devils is probably to blame.

Remember, what helps you break out of your plateau today will one day stop working – and you'll have to try another method. Breaking through plateaus, as you've seen, is a constant recalibration – it takes a little of this and a bit of that. In the list below, we show you what "this" and "that" really are for you, today, and into the future. These solvents produce solutions.

Element 1: Immunity

People, relationships, businesses and even physical processes become immune to the same techniques, the same approaches, the same solutions. Immunity is perhaps the most basic force of the Plateau Effect. Everybody has experienced what it's like to become immune to something: maybe it's the complements of your spouse, the smell of garlic at an Italian restaurant, or the effects of your second beer. Immunity can be frustrating – what worked so well yesterday just won't work today.

Solvent: Diversity

Immunity's Kryptonite is diversity. You've got to shake things up and be radical. Trying different approaches, techniques or procedures can shake you out of an immunity plateau.

Element 2: Greedy Algorithm

The greedy algorithm is a concept borrowed from the field of mathematics. Here's how it works: you always pick the best short-term solution and ignore the long-term outcome. As it is in mathematics – and in life – the best short-term solution hardly ever leads to the best long-term outcome. The greedy algorithm always finds the locally optimal solution but ignores the globally optimal solution.

Solution: Extend your gratification horizon

Short-term greed is bad but long-term greed is actually good. To get beyond the greedy algorithm, you need to think about solutions on a bigger timescale. Someone following the greedy algorithm (driven by short-term greed) would never go to medical school – the student is building debt with no income year after year. Someone who's thinking about a 10-year horizon instead of a 1-2 year horizon sees the six-figure checks that will eventually start coming in.

Element 3: Bad Timing

If you're working hard but you're stuck in a plateau, maybe it's as simple as taking a break. When you do something – and more precisely, when you don't do something – is critical.

The key is to take control of when you apply effort, not just how much effort you apply.

Solution: Wait

If bad timing has you stuck in a plateau, remember, the periods of rest and inactivity are just as important as the periods of great effort, just as silence between the notes is part of the music. If you use time as a tool, you can literally wait your way out of a plateau.

Element 4: Flow Issues

Whenever things seem to be sailing along, sometimes the engine just breaks down.

Specifically, you can run into one of four dysfunctions:

Erosion: Sometimes we deplete the resources that we need to be successful. Maybe we run out of capital, or time, or skilled workers. When you hit an erosion plateau, progress tends to degrade slowly as some critical resource is gobbled up over time.

Solvent: Find a counterbalance, something that replaces the resource you consume. If you can't find a counterbalance, you might not be in a plateau at all. You may have reached a terminal point.

Step Function: Sometimes you want to add just a little more of something, but that thing is only available in bundles. The result is a jump in cost, effort, or benefit. We call these things "step functions." If you aren't aware that something you need follows a step function, you can hit a plateau because incremental investment won't lead to incremental improvement.

Solvent: Try to smooth out your step function. Sometimes this can be done by identifying some other person or business that has complementary peaks to your own. If you can pool your resources, you can share the cost of the step and make it look more like a comfortable ramp.

Choke points: A choke point is the part of the system that breaks first and slows everything else down. Failing to identify a chokepoint can bring a gushing flow to an unexpected trickle.

Solvent: The trick is to find out where the choke point is and creatively route your way around it.

Mystery ingredients: The defining characteristic of a mystery ingredient is that even the chef doesn't know what it is. The mystery ingredient could be changing market conditions, interpersonal issues between co-workers, or just a team member with a can-do attitude. It's the elusive catalyst that makes things work.

Solvent: Mystery ingredients can often be hard to find, but seem obvious in retrospect. Often, it's just important to recognize that a mystery ingredient might exist; that what you see isn't the whole story.

Element 5: Distorted Data

We often react based on distorted data. It's like walking through a hall of mirrors, and basing a major decision on the crazy fat (or skinny) image you see. Sometimes we measure the wrong things or inappropriately assess risk. In other cases, we fall victim to common psychological errors with data, such as overweighing the most recent piece of information we've received, we get hung up on sunk costs, or we conform to what we think the data is telling us.

Solvent: Recalibrate

The Enlightenment brought us the scientific method because smart people realized that they couldn't trust their own eyes. The key is to boil out the impurities of data and recognize that you are looking through a lens that might be deceptive. Each type of distortion has its own remedy, but the tie that binds them is to look for a ground truth of data amidst the chaos.

Element 6: Distraction

It's easy to fall victim to the illusion of multitasking and become distracted. Distraction is the enemy of adaptation and can lead you straight towards a plateau. How do we know when and what we need to change to live in a world of unrelenting distraction?

Solvent: Radical Listening

If you take a page from improv comedy – where you look for the truth in what others are saying and build on it through the “yes....and” strategy – you get to a skill we call radical listening. It’s a mode of active engagement, where you are attuned to your surroundings, listening, and adapting.

Element 7: Failing Slowly

Failing slow is natural because it’s difficult to tell that a situation is incrementally getting worse. Often the incremental worsening of a situation happens slower than what psychophysicists call the just noticeable difference. The just noticeable difference helps explain why we continue forging ahead when we’re in the throes of a plateau – we just don’t realize how much less we’re getting for our efforts.

Solution: Fail fast

Once you understand the just noticeable difference you can counteract its effects. By setting clear markers, you can objectively see how you’re progressing, figure out what’s working and what’s failing, correct it and move on. It’s important to realize if your efforts will eventually fail by accelerating failure. This ability to fail fast is key, especially when the problems are changing quickly.

Element 8: Perfectionism

Perfect is the enemy of good. The desire for perfection kills beginnings – it’s never the right time to start, and even if you do, a task is never complete because it is held up to an impossible standard. A plateau of perfection is similar to a plateau of inaction.

Solution: First Steps, etc.

Accept that perfection isn’t achievable. Focus on taking the first step, and then the next step. There are some tricks that can help, such as structured procrastination and setting hard (but liberating) deadlines.

14. 66 Personal Development Habits For Smart People

Steve Pavlina's book, Personal Development for Smart People: The Conscious Pursuit of Personal Growth, offers an interesting look at self-improvement.

"Perception is the most basic aspect of truth," Pavlina writes, "If you want to improve some part of your life, you have to look at it first."

For example, if you want to know how your relationship is doing, you ask yourself "How do I feel about this relationship? What parts are working well? What parts need improvement?" Ask your partner the same questions and compare your answers. Figuring out where you stand will help you decide what changes you'd like to make. Perception is a key component of personal growth because we react to what we perceive to be true.

The first step "must be to recognize that your life as it stands right now isn't how you want it to be."

It's easy to say you should face the cold, hard, truth but in practice it can be very difficult.

However:

You can't get from point A to point B if you refuse to acknowledge that you're at point A!

There are two powerful ways you can apply your mind's predictive powers to accelerate your personal growth:

First, by embracing new experiences that are unlike anything you've previously encountered, you'll literally become more intelligent.

New situations shift your mind into learning mode, which enables you to discover new patterns. The more patterns your mind learns, the better it gets at prediction, and the smarter you become.

Read a book on a topic that's completely alien to you. Talk to people you'd normally avoid. Visit an unfamiliar city. Stretch beyond the patterns your mind has already learned. In order to grow, you must repeatedly tackle fresh challenges and consider new ideas to give your mind fresh input. If you merely repeat the same experiences, you'll stagnate, and your mental capacity will atrophy.

If you want to become smarter, you must keep stirring things up.

The second way to apply your mind's predictive powers is to make conscious, deliberate predictions and use those predictions to make better decisions. Think about where you're headed and ask yourself, "How do I honestly expect my life to turn out?"

Imagine that a very logical impartial observer examines your situation in detail, and predicts what your life will look like in 20 years, based on your current behavior. What kind of future will this person predict for you? If you're brave enough, ask several people who know you well to give you an honest assessment of where they see you in two decades. Their answers may surprise you.

A list of habits that can boost personal effectiveness (hacked and lightly edited):

1. Daily goals. Set targets for each day in advance. Decide what you'll do, then do it. Without a clear focus, it's too easy to succumb to distractions.
2. Worst first. To defeat procrastination, learn to tackle your most unpleasant task first thing in the morning, instead of delaying it until later. The small victory will set the tone for a very productive day.
3. Peak times. Identify your peak cycles of productivity, and schedule your most important tasks for those times. Work on minor tasks during your non-peak times.
4. No-comm zones. Allocate uninterruptible blocks of time for solo work where you must concentrate. Schedule light, interruptible tasks for your open-communication periods and more challenging projects for your blackout periods.

5. Mini-milestones. When you begin a task, identify the target you must reach before you can stop working. For example when writing a book, you could decide not to get up until you've written at least 1000 words. Hit your target no matter what.
6. Timeboxing. Give yourself a fixed time period – 30 minutes for example – to make a dent in a task. Don't worry about how far you get. Just put in the time.
7. Batching. Batch similar tasks such as phone calls or errands together, and knock them out in a single session.
8. Early bird. Get up at 5am and go straight to work on your most important task. You can get more done before 8am than most people do in a full day.
9. Pyramid. Spend 15-30 minutes doing easy tasks to warm up, then tackle your most difficult project for several hours. Finally end with another 15-30 minutes of easy tasks to transition out of work mode.
10. Tempo. Deliberately pick up the pace, and try to move a little faster than usual. Speak faster. Walk faster. Type faster. Read faster. Go home sooner.
11. Relaxify. Reduce stress by cultivating a relaxing, clutter-free workspace.
12. Agendas. Provide clear written agendas to meeting participants in advance. This greatly improves meeting focus and efficiency. You can use it for phone calls too.
13. Pareto. The Pareto principle is the 80-20 rule, which states that 80% of the value of a task comes from 20% of the effort. Focus your energy on that critical 20%, and don't overengineer the non-critical 80%.
14. Ready-fire-aim. Bust procrastination by taking action immediately after setting a goal, even if the action isn't perfectly planned. You can always adjust course along the way.
15. Minuteman. Once you have the information you need to make a decision, start a timer and give yourself just 60 seconds to make the actual decision. Take a whole minute to vacillate and second-guess yourself all you want, but come out the other end with a clear choice. Once your decision is made, take some kind of action to set it in motion.
16. Deadline. Set a deadline for task completion, and use it as a focal point to stay on track.
17. Promise. Tell others of your commitments, since they'll help hold you accountable.
18. Punctuality. Whatever it takes, show up on time. Arrive early.
19. Gap reading. Use reading to fill in those odd periods like waiting for an appointment, standing in line, or while the coffee is brewing. If you're a male, you can even read an article while shaving (preferably with an electric razor). That's 365 articles a year.
20. Resonance. Visualize your goal as already accomplished. Put yourself into a state of actually being there. Make it real in your mind, and you'll soon see it in your reality.
21. Glittering prizes. Give yourself frequent rewards for achievement. See a movie, book a professional massage, or spend a day at an amusement park.

22. **Priority.** Separate the truly important tasks from the merely urgent. Allocate blocks of time to work on the critical Quadrant 2 tasks, those which are important but rarely urgent, such as physical exercise, writing a book, and finding a relationship partner.
23. **Continuum.** At the end of your workday, identify the first task you'll work on the next day, and set out the materials in advance. The next day begin working on that task immediately.
24. **Slice and dice.** Break complex projects into smaller, well-defined tasks. Focus on completing just one of those tasks.
25. **Single-handling.** Once you begin a task, stick with it until it's 100% complete. Don't switch tasks in the middle. When distractions come up, jot them down to be dealt with later.
26. **Randomize.** Pick a totally random piece of a larger project, and complete it. Pay one random bill. Make one phone call. Write page 42 of your book.
27. **Insanely bad.** Defeat perfectionism by completing your task in an intentionally terrible fashion, knowing you need never share the results with anyone. Write a blog post about the taste of salt, design a hideously dysfunctional web site, or create a business plan that guarantees a first-year bankruptcy. With a truly horrendous first draft, there's nowhere to go but up.
28. **Delegate.** Convince someone else to do it for you.
29. **Cross-pollination.** Sign up for martial arts, start a blog, or join an improv group. You'll often encounter ideas in one field that can boost your performance in another.
30. **Intuition.** Go with your gut instinct. It's probably right.
31. **Optimization.** Identify the processes you use most often, and write them down step-by-step. Refactor them on paper for greater efficiency. Then implement and test your improved processes. Sometimes we just can't see what's right in front of us until we examine it under a microscope.
32. **Super Slow.** Commit yourself to working on a particularly hideous project for just one session a week, 15-30 minutes total. Declutter one small shelf. Purge 10 clothing items you don't need. Write a few paragraphs. Then stop.
33. **Dailies.** Schedule a specific time each day for working on a particular task or habit. One hour a day could leave you with a finished book, or a profitable Internet business a year later.
34. **Add-ons.** Tack a task you want to habitualize onto one of your existing habits. Water the plants after you eat lunch. Send thank-you notes after you check email.
35. **Plug-ins.** Inject one task into the middle of another. Read while eating lunch. Return phone calls while commuting. Listen to podcasts while grocery shopping.
36. **Gratitude.** When someone does you a good turn, send a thank-you card. That's a real card, not an e-card. This is rare and memorable, and the people you thank will be eager to bring you more opportunities.
37. **Training.** Train up your skill in various productivity habits. Get your typing speed to at least 60wpm, if not 90.

38. Denial. Just say no to non-critical requests for your time.
39. Recapture. Reclaim other people's poor time usage for yourself. Visualize your goals during dull speeches. Write out your grocery list during pointless meetings.
40. Mastermind. Run your problem past someone else, preferably a group of people. Invite all the advice, feedback, and constructive criticism you can handle.
41. Write down 20 creative ideas for improving your effectiveness.
42. Challenger. Deliberately make the task harder. Challenging tasks are more engaging than boring ones. Compose an original poem for your next blog post. Create a Power Point presentation that doesn't use words.
43. Asylum. Complete an otherwise tedious task in an unusual or crazy manner to keep it fun or interesting.
44. Music. Experiment with how music can boost your effectiveness.
45. Scotty. Estimate how long a task will take to complete. Then start a timer, and push yourself to complete it in half that time.
46. Pay it forward. When an undesirable task is delegated to you, re-delegate it to someone else.
47. Bouncer. When a seemingly pointless task is delegated to you, bounce it back to the person who assigned it to you, and challenge them to justify its operational necessity.
48. Opt-out. Quit clubs, projects, and subscriptions that consume more of your time than they're worth.
49. Decaffeinate. Say no to drugs, suffer through the withdrawal period, and let your natural creative self re-emerge.
50. Conscious procrastination. Delay non-critical tasks as long as you possibly can. Many of them will die on you and won't need to be done at all.
51. TV-free. Turn off the TV, especially the news, and recapture many usable hours.
52. Timer. Time all your tasks for an entire day, preferably a week. Even the act of measuring itself can boost your productivity, not to mention what you learn about your real time usage.
53. Valor. Pick the one item on your task list that scares you the most. Muster all the courage you can, and tackle it immediately.
54. Nonconformist. Run errands at unpopular times to avoid crowds. Shop just before stores close or shortly after they open. Take advantage of 24-hour outlets if you're a vampire.
55. Agoraphobia. Shop online whenever possible. Get the best selection, consult reviews, and purchase items within minutes.
56. Reminder. Add birthday and holiday reminders to your calendar a month or two ahead of their actual dates. Buy gifts then instead of at the last minute.

57. Do it now! Recite this phrase over and over until you're so sick of it that you cave in and get to work.
58. Coach. Hire a personal coach to keep yourself motivated, focused, and accountable. After several months of pep talks, you'll be qualified to start your own coaching practice.
59. Inspiration. Read inspiring books and articles, listen to audio programs, and attend seminars to keep absorbing inspiring new ideas (as well as to refresh yourself on the old ones).
60. Gym rat. Exercise daily. Boost metabolism, concentration, and mental clarity in 30 minutes a day.
61. Troll hunt. Banish the negative trolls from your life, and associate only with positive, happy, and successful people. Mindsets are contagious. Show loyalty to your potential, not to your pity posse.
62. Anakin. Would your problems be easier to solve if you turned evil? The dark side beckons...
63. Politician. Outsource your problems. How many can be solved more easily if you define them in financial terms? ...
64. Modeling. Find people who are already getting the results you want, interview them, and adopt their attitudes, beliefs, and behavior.
65. Proactivity. Even if others disagree with you, take action anyway, and deal with the consequences later. It's easier to request forgiveness than permission.
66. Real life. Give online life a rest, and reinvest that time into your real offline life, which, if you're a gamer, is probably suffocating beneath a pile of dead smelly orcas.

15. Improving Performance

Source: Seeing What Others Don't: The Remarkable Ways We Gain Insights

Via [Seeing What Others Don't: The Remarkable Ways We Gain Insights](#) (Kindle)

To improve performance, we need to do two things. The down arrow is what we have to reduce, errors. The up arrow is what we have to increase, insights. Performance improvement depends on doing both of these things.

We tend to look for ways to eliminate errors. That's the down arrow. But if we eliminate all errors we haven't created any insights. ...

Ideally, reducing mistakes would at least help us gain insights but I don't believe that's how it works. I suspect the relation between the arrows runs the other way. When we put too much energy into eliminating mistakes, we're less likely to gain insights. Having insights is a different matter from preventing mistakes.

When I showed this slide in my seminars, I got a lot of head nods. The participants agreed that their organizations were all about the down arrow. They felt frustrated by organizations that stifled their attempts to do a good job. Their organizations hammered home the message of reducing mistakes, perhaps because it is easier for managers to cut down on mistakes than to encourage insights. Mistakes are visible, costly, and embarrassing.

16. Three (Underrated) Reasons for Berkshire Hathaway's Success

Berkshire Hathaway is widely regarded as one of the most successful companies in the world. If you look at Warren Buffett's 49 year track record with Berkshire, it almost looks easy in hindsight. Make no mistake, however, it wasn't easy and he certainly didn't do it alone.

At this year's annual meeting Buffett and his longtime business partner, Charlie Munger, revealed "*the secret*" to their success. But it's not really a secret and, of course, extraordinary success is typically a combination of many things.

Underrated Factors that Enable Success

Here are three underrated factors that carried the bulk of the weight to creating Berkshire's success. Oddly, I don't think you'll find them on any business school curriculum.

1. Trust

Buffett is famous for his hands-off management style. He lets the CEOs of the companies run their show; he only asks that they send him the money they can't use.

Good people want to work with him and this is important because most of the people running Berkshire subsidiaries are already wealthy. They don't *have* to come to work; they *want* to come to work. And that is a huge difference. The only time you can get away with a crappy bureaucracy and a culture of distrust is when people *have* to come to work. *"By the standards of the rest of the world, we over-trust. And so far, our results have been far better, because we carefully selected people who should be over-trusted"*

— Charlie Munger

Every now and then something happens at a Berkshire company that calls into question his near abdication of responsibility to a subsidiary. "If only he had been paying attention," the critics chirp, "this wouldn't have happened." Those finger-waving critics are idiots. The alternative approaches are worse, not better.

There are many positives to the approach Buffett takes.

If Buffett closely managed each of his subsidiary CEOs to the point where most bosses manage their subordinates, they'd probably quit. If he sent out memos telling them all to use a new corporate HR system, they'd stop wanting to come to work. In fact Berkshire, a company with over 300,000 employees, has no HR department. If he peppered them with relentless emails from "headquarters" on some new policy, they'd ... well how do you feel about all of this stuff?

With Berkshire, Buffett wanted to do things his way. He wanted to paint his own canvas. He didn't want other people telling him to add a little more blue here and take away a little red there. Most people want to run their own show. And the best part? This system gets more out of people than micromanaging them.

Sure sometimes things go wrong, but for the most part the outcome is positively skewed. Things go wrong in other corporate cultures, they are not immune. When things go wrong in bureaucratic cultures, however, it's nearly impossible to hold anyone accountable because no one is really responsible for anything. And it's hard to hold people accountable when they are not responsible. It's a seductive illusion to think that we can create a system where people can't mess up. Buffett's hands-off approach makes it clear who is responsible for what. And this approach, not stock options, creates a *real* ownership culture.

This system also frees up Buffett's time. He doesn't have to chase management details, read power-points, etc. He can sit and read and think — that means he does what he does best. And judging by the results, this has worked out well.

Hiring the right people and trusting them is incredibly underrated and yet nearly impossible to find in large established bureaucratic organizations. Yet as Buffett shows, it's a much better approach. Trust is incredibly powerful.

2. (Quickly) Scramble Out of Your Mistakes

You know the old adage, when you find yourself in a hole the first thing to do is stop digging. That applies to business as well as life.

In the late 1960s Buffett acquired a department store, Hochschild-Kohn, through a company called Diversified Retailing, which later merged with Berkshire.

"It's a learning process, and mistakes made in one year often contribute to competence and success in succeeding years."

— Warren Buffett

The people running the company were, in Buffett's words, "first-class." Retailing, however, is a difficult industry, even with a first-class management team. They were, in Buffett's words, "running in quicksand." Realizing this quickly after the ink dried on the contract, Berkshire "scrambled" out of it, selling Hochschild-Kohn as quickly as they could — 3 years.

Business schools don't generally teach this either. What they teach and reinforce, in so many ways, is that you can be the hero. You can be the exception to the base rate.

But in life and business, you don't need to be the hero. There are no points for difficulty, so as Munger alluded to, smart people will play where competition is weak.

You can have the best management team that money can buy and still fail big in retailing — a recent example being JC Penney.

Buffett learned quickly that, in his words, "When a management with a reputation for brilliance tackles a business with a reputation for bad economics, it is the reputation of the business that remains intact."

3. Remove Ignorance

Diversified Retailing also owned shares in a better business: Blue Chip Stamps, which provided supermarkets and other retailing outlets trading stamps to give their customers that could be exchanged for merchandise.

"See's has provided us with lots of cash for acquisitions and opened my eyes to the power of brands. We made a lot in Coca-Cola partly because of See's. There's something about owning [a brand] to educate yourself about things you might do in the future. I wouldn't be at all surprised that if we hadn't owned See's, we wouldn't have bought Coca-Cola."

— Warren Buffett

The contrast between running a good business and a poor one stuck with Munger and Buffett and they decided to pay up for a real quality business. On January 3, 1972 Blue Chip Stamps bought See's Candies, a West Coast Manufacturer and retailer of boxed-chocolates. See's is an *extraordinary* business.

As a great business, most people think that See's main contribution to Berkshire was its overwhelming financial success. It wasn't. According to Munger, See's main contribution was "ignorance removal."

"We were barely smart enough to buy it," he said. See's taught them a powerful lesson, the value of strong brand names.

Without See's, they never would have purchased Coke shares in the 80s. And without Coke, Berkshire would be a lot less prosperous today as that investment has been one of their best.

"If there's any secret we have, it's ignorance removal. And the nice thing is we still have a lot of ignorance left to remove," Munger said at the 2014 Shareholders meeting.

Removing ignorance is about continuously getting smarter. Avoiding stupidity is easier than seeking brilliance.

I don't know why more people don't copy these three underrated factors to Berkshire's success.

To sum up:

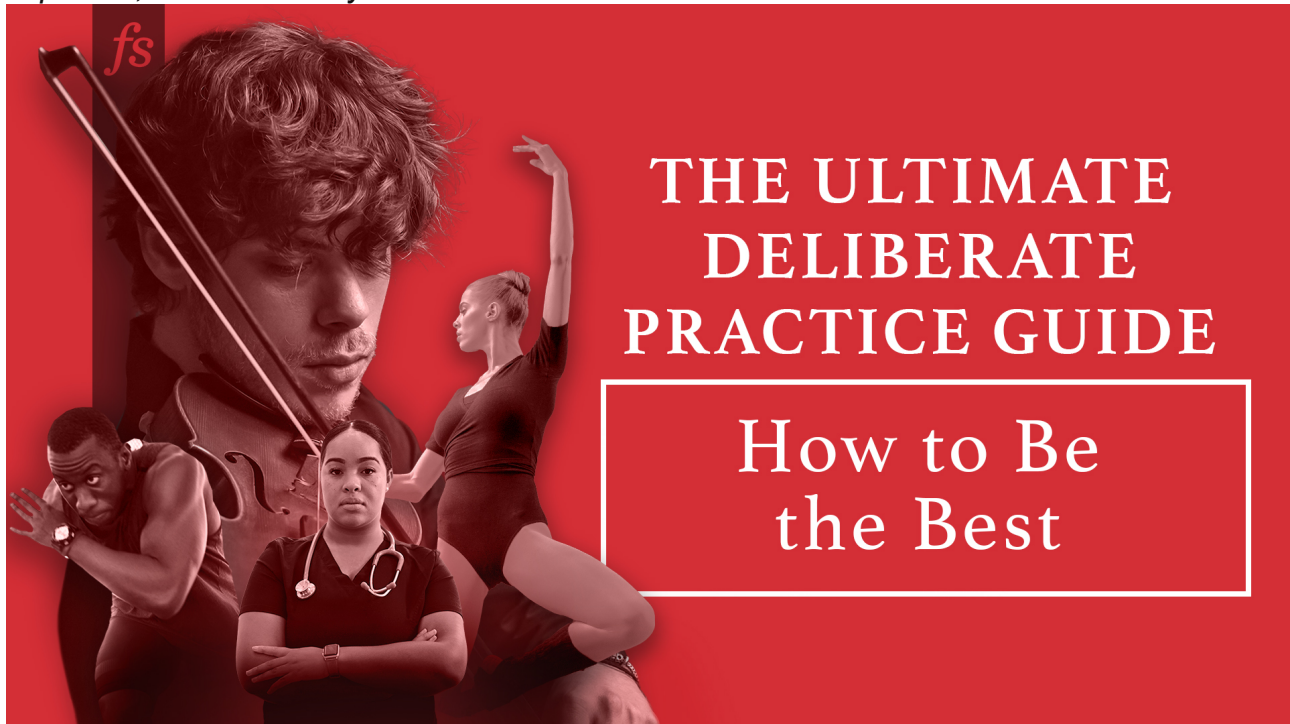

1. Hire good people and trust them.
2. Quickly admit mistakes and scramble out of them.
3. Remove your ignorance by always learning.

This formula is simple but not easy.

17. The Ultimate Deliberate Practice Guide: How to Be the Best

Everything You Need to Know to Improve Your Performance at Anything—For Beginners and Experts

Deliberate practice is the best technique for achieving expert performance in every field—including writing, teaching, sports, programming, music, medicine, therapy, chess, and business. But there's much more to deliberate practice than 10,000 hours. Read this to learn how to accelerate your learning, overcome the "OK" plateau, turn experience into expertise, and enhance your focus.

What is deliberate practice?

*“Engaged in the creative process we feel more alive than ever, because we are making something and not merely consuming, masters of the small reality we create. In doing this work, we are in fact creating ourselves.” —Robert Greene, *Mastery**

Deliberate practice is what turns amateurs into professionals. Across every field, deliberate practice is what creates top performers and what they use to stay at the top of their game. It's absolutely essential for expert performance.

As a general concept, “practice” means preparing. It's the act of repeatedly performing certain activities with the intention of improving a specific associated skill. We rehearse what to do in low-pressure situations so we'll be better when we use a skill in situations where something is actually at stake, such as in a competition or in the workplace.

Although this definition may seem obvious, it's crucial to distinguish between doing something and practicing it, because they're not always synonymous.

The key distinction between doing and practicing is that we're only practicing something when we do it in a way that makes us better at it—or at least with that intention.

Deliberate practice means practicing with a clear awareness of the specific components of a skill we're aiming to improve and exactly how to improve them. Unlike regular practice, in which we work on a skill by repeating it again and again until it becomes almost mindless, deliberate practice is a laser-focused activity. It requires us to pay unwavering attention to what we're doing at any given moment and whether it's an improvement or not.

Geoff Colvin summarizes deliberate practice as such in *Talent Is Overrated*:

Deliberate practice is characterized by several elements, each worth examining. It is activity designed specifically to improve performance, often with a teacher's help; it can be repeated a lot; feedback on results is continuously available; it's highly demanding

mentally, whether the activity is purely intellectual, such as chess or business-related activities, or heavily physical, such as sports; and it isn't much fun.

The extraordinary power of deliberate practice is that it aims at constant progress. Practitioners are not content with repeating a skill at the same level. They have metrics for measuring their performance. And they aspire to see those metrics get continuously better. While engaging in deliberate practice, we are always looking for errors or areas of weakness. Once we identify one, we establish a plan for improving it. If one approach doesn't work, we keep trying new ones until something does.

Using deliberate practice, we can overcome many limitations that we might view as fixed. We can go further than we might even think possible when we begin. Deliberate practice creates new physical and mental capabilities—it doesn't just leverage existing ones. The more we engage in deliberate practice, the greater our capabilities become. Our minds and bodies are far more malleable than we usually realize.

Deliberate practice is a universal technique, and you can employ it for whatever you're trying to be the best (or just get a little bit better) at. It's easiest to apply to competitive fields with clear measurements and standards, including music, dance, football/soccer, cricket, hockey, basketball, golf, horse riding, swimming, and chess.

But deliberate practice is also invaluable for improving performance in fields such as teaching, nursing, surgery, therapy, programming, trading, and investing. It can even accelerate your progress in widely applicable skills such as writing, decision-making, leadership, studying, and spoken communication.

The key in any area is to identify objective standards for performance, study top performers, and then design practice activities reflecting what they do. Recent decades have seen dramatic leaps in what people are capable of doing in many fields. The explanation for this is that we're getting better at understanding and applying the principles of deliberate practice. As a field advances, people can learn from the best of what those who came before them figured out. The result is that now average high-schoolers achieve athletic feats and children advance to levels of musical prowess that would have seemed unthinkable a century earlier. And there's little evidence to suggest we've reached the limits of our physical or mental abilities in any area whatsoever.

Many of us spend a lot of time each week practicing different skills in our lives and work. But we don't automatically get better just because we repeat the same actions and behaviors, even if we spend hours per day doing it. Research suggests that in areas such as medicine, people with many years of experience are often no better than novices—and may even be worse.

If we want to improve a skill, we need to know *what* exactly has to change and what might get us there. Otherwise, we plateau.

Some people will tell you it's only possible for anyone to improve at anything through deliberate practice, and any other sort of practice is a waste of time. This is an exaggeration. In reality, regular practice works for reinforcing and maintaining skills. It can also help us improve skills, particularly in the early stages of learning something. However, deliberate practice *is* the only way to:

1. Reach expert-level performance and enjoy competitive success
2. Overcome plateaus in our skill level
3. Improve at a skill much faster than through regular practice

If you're just doing something for fun and don't care about constantly improving at it, you don't need deliberate practice. For example, maybe you like to go for a walk around a local park in the afternoons to clear your head. Although you're practicing that walk each time you go, you probably don't care about increasing your walking speed day by day. It's

enough that the repetitions further ingrain the habit and help maintain a certain level of physical fitness. Not everything in life is a competition! But if you want to keep getting better at something as fast as possible or reach an expert level, deliberate practice is vital. Another important point to note is that deliberate practice isn't just a catchy name we came up with out of thin air. The term is largely attributed to Karl Anders Ericsson, one of the most influential figures of all time in the field of performance psychology. It's something many scientists have studied for decades. Everything we say here is supported by substantial academic research, particularly Ericsson's work. We'll also debunk the numerous myths swirling around deliberate practice as a concept and reveal some of its significant limitations. So if you're looking for quick hacks for overnight success, you might want to look elsewhere. If you want a realistic roadmap for improving your performance, read on.

If we want to improve a skill,
we need to know what exactly
has to change and what
might get us there.

“

fs

The elements of deliberate practice

“Life is not always a matter of holding good cards, but sometimes, playing a poor hand well.” —Jack London

In this section, we'll break down the fundamental elements of deliberate practice and exactly how to incorporate them into your practice sessions. As Ericsson wrote in *Peak*, *“No matter what the field, the most effective approach to improving performance is to follow a single set of principles.”* We'll explain why each component is crucial and how they apply to different fields, and we'll cover multiple ways to implement them depending on your goals.

Deliberate practice is structured and methodical

“Everyone has talent. What's rare is the courage to follow it to the dark places where it leads.” —Erica Jong

As humans, we're wired to want to do the easiest thing at all times in order to conserve energy. Put more simply, it's in our nature to be lazy. When we practice something a lot, we develop habits that become almost effortless to enact. While that's beneficial in many areas of our lives (and helps us survive), it's something we have to overcome in order to engage in deliberate practice. We can't expect constant improvement if we keep repeating the elements of a skill we already know how to do with ease. That's only enough if we're just having fun or want to reinforce our habits.

Deliberate practice is structured to improve specific elements of a skill through defined techniques. Practitioners focus above all on what they *can't* do. They seek out areas of weaknesses impacting their overall performance, then target those. At every stage, they set tailored, measurable goals in order to gauge whether their practice is effective at moving them forwards. Numbers are a deliberate practitioner's best friend.

If you want to reach an expert level of performance, you need to begin practice sessions with a plan in mind. You need to know what you're working on, why, and how you intend to improve it. You also need a way to tell if your improvement efforts aren't working and if you need to try a new tactic. Once you reach your goal for that particular component of the skill, it's time to identify a new area of weakness to work on next.

Having lots of little, realistic goals with a game plan for achieving them makes deliberate practice motivating. There's a sense of ongoing movement, yet the next step is always a realistic stretch. Day by day, the gains from deliberate practice may feel modest. But when we look back over a longer period of time, small bits of progress compound into gigantic leaps.

How to implement this: Take the skill you're aiming to improve and break it down into the smallest possible component parts. Make a plan for working through them in a logical order, beginning with the fundamentals, then building upon them. Decide which parts you'd like to master over the next month. Put your practice sessions in your calendar, then plan precisely which parts of the skill you're going to work on during each session.

Don't expect your plan to be perfect. You'll likely need to keep modifying it as you discover new elements or unexpected weaknesses. The most important thing is to always go into practice with a plan for what you're working on and how. Knowing what you're doing next is the best way to stay on track and avoid aimless time-wasting. That means seeking to keep figuring out what separates you from the next level of performance so you can concentrate on that.

Deliberate practice is challenging and uncomfortable

"One must develop an instinct for what one can just barely achieve through one's greatest efforts." —Albert Einstein (attributed)

Imagine the world from the perspective of a baby learning to walk for the first time. It's not usually an easy process. They need to develop a lot of new skills and capabilities. They need to build enough muscular strength to stand upright without support. And they need to learn how to coordinate their limbs well enough to move around. Along the way, a baby needs to develop numerous sub-skills, such as how to grip supports to pull themselves up. It likely takes thousands of attempts to master walking—as well as numerous, falls, collisions, and other mishaps. We might not remember the process as adults, but a baby learning to walk needs to spend many hours challenging themselves and moving incrementally out of their comfort zone.

If we want to use deliberate practice, we could do with learning a thing or two from babies. Deliberate practice isn't necessarily fun while we're doing it. In fact, most of the time it's a process of repeated frustration and failure. We have to fall down a dozen times for every step we take. That's the whole point.

Seeing as deliberate practice requires us to keep targeting our weakest areas, it means spending time doing stuff we're not good at. In the moment, that can feel pretty miserable. But the quickest route to improvement involves stepping outside of our comfort zones.

The reason why people who have spent decades doing something are not necessarily better than newbies is that they're liable to get complacent and stop pushing themselves. We need to keep attempting to do things that feel out of reach at the moment.

In his studies of elite violinists, Ericsson asked them to rate different practice activities by how enjoyable they were and how much they contributed to improving performance.

Invariably, there was an inverse correlation between the usefulness of an activity and its enjoyability. As Ericsson puts it in *Peak*:

The reason that most people don't possess these extraordinary physical capabilities isn't because they don't have the capacity for them, but rather because they're satisfied to live in the comfortable rut of homeostasis and never do the work that is required to get out of it. They live in the world of "good enough." The same thing is true for all the mental activities we engage in.

Elsewhere in the book, he writes *"This is a fundamental truth about any sort of practice: If you never push yourself beyond your comfort zone, you will never improve."* The interesting part is the more time you spend deliberately practicing, the more comfortable you'll become with being uncomfortable.

Daniel Coyle writes in *The Little Book of Talent*:

There is a place, right on the edge of your ability, where you learn best and fastest. It's called the sweet spot. . . . The underlying pattern is the same: Seek out ways to stretch yourself. Play on the edges of your competence. As Albert Einstein said, "One must develop an instinct for what one can just barely achieve through one's greatest efforts." The key word is 'barely.'

A quick way to assess if you're doing deliberate practice or just regular rote practice is to ask yourself if you ever feel bored or zone out during practice sessions. If the answer is yes, you're probably not practicing deliberately.

Deliberate practice isn't boring. Frustrating, yes. Maddening, yes. Annoying, even. But never boring. As soon as practicing a skill gets comfortable, it's time to up the stakes. Challenging yourself is about more than trying to work harder—it means doing new things. Pushing ourselves just beyond the limits of our abilities is uncomfortable, yet it's how we do our best—and indeed, it can be the source of some of our greatest moments of satisfaction. According to psychologist Mihaly Csikszentmihalyi, we often experience happiness as a result of entering a "flow" state, which occurs when we intensely focus on an activity that is challenging yet achievable. During moments of flow, we become so immersed in the activity that we lose any sense of time or of ourselves.

Noel Tichy, professor at the University of Michigan business school and the former chief of General Electric's famous management development center at Crotonville, puts the concept of practice into three zones: the comfort zone, the learning zone, and the panic zone.

Most of the time when we're practicing, we're really doing activities in our comfort zone. This doesn't help us improve because we can already do these activities easily. On the other hand, operating in the panic zone leaves us paralyzed, as the activities are too difficult and we don't know where to start. The only way to make progress is to operate in the learning zone, which are those activities that are just out of our reach.

Repetition inside the comfort zone does not equal deliberate practice. Deliberate practice requires that you operate in the learning zone and you repeat the activity a lot with feedback.

How to implement this: Each time you practice a component of a skill, aim to make it 10% harder than the level you find comfortable.

Once per month, have a practice session where you set yourself an incredibly ambitious stretch goal—not impossible, just well above your current level. Challenge yourself to see how close you can get to it. You might surprise yourself and find you perform far better than expected.

A common deliberate practice mistake is to plan a long practice session, then adjust the intensity of your practice to allow you to engage in a skill for the whole time. It's far more effective to engage in "sprints." Practice with the most intense focus you can manage for short periods of time, then take breaks. Seeing as you learn most when you stretch yourself beyond your current capabilities, shorter, more challenging practice periods are the way to go.

Deliberate practice requires rest and recovery time

“There is a time for many words, and there is also a time for sleep.” —Homer, The Odyssey

Seeing as deliberate practice is so challenging, it’s impossible to do it all day long. Across fields, top practitioners rarely spend more than around three to five hours per day on deliberate practice, at the high end. They may work for more hours than that per day, but few can sustain the mental energy to engage in deliberate practice for eight hours a day. Additional hours often result in diminishing negative returns, meaning more practice makes performance worse because it results in burnout. Geoff Colvin writes:

The work is so great that it seems no one can sustain it for very long. A finding that is remarkably consistent across disciplines is that four or five hours a day seems to be the upper limit of deliberate practice, and this is frequently accomplished in sessions lasting no more than an hour to ninety minutes.

Ericsson’s studies of elite violinists found they often took afternoon naps and slept an average of eight hours per night, considerably more than the average person. They were highly aware of the importance of sleep.

Even fitting in a single hour per day of deliberate practice is ample time to make substantial improvements, especially when we’re consistent with committing to it over the long haul. Continuous investments in success compound. In the long run, commitment pays off.

Not only do most deliberate practitioners not spend all day at it, they also devote a lot of time to recuperation and recovery. They sleep as much as their bodies need. They nap if necessary. They take frequent, refreshing breaks. Most of us understand that rest is necessary after physical activity. But we can underestimate its importance after mental activity, too. Deliberate practice needs to be sustainable for the long term. How long a person keeps at a skill is often far more important than how many hours a day they spend on it.

When you’re practicing deliberately, truly practice. When you’re recuperating, truly relax. No one can spend every waking hour on deliberate practice.

Sleep is a vital part of deliberate practice. Being asleep doesn’t mean you’re not still improving your skill. We consolidate memories at night, moving them from short-term to long-term memory. And we can’t exactly benefit from deliberate practice sessions if we don’t remember what we learn each time. Not only that, but sleep deprivation also results in a plethora of negative cognitive effects that impact performance. If we skimp on sleep, we’re likely to forget far more of what we learn during deliberate practice sessions, rendering them less useful.

When you’re not engaging in deliberate practice, your brain is still at work. During deliberate practice, we’re in focused mode. When we let our minds wander freely while at rest, we’re in diffuse mode. Although that time feels less productive, it’s when we form connections and mull over problems. Both modes of thinking are equally valuable, but it’s the harmony between them that matters. We can’t maintain the effort of the focused mode for long. At some point, we need to relax and slip into the diffuse mode. Learning a complex skill—a language, a musical instrument, chess, a mental model—requires both modes to work together. We master the details in focused mode, then comprehend how everything fits together in diffuse mode. It’s about combining creativity with execution. How to implement this: Make a list of activities you can engage in without too much conscious thought, letting yourself daydream while you do them. Common examples include going for a walk, washing the dishes, taking a shower, free-writing in a journal, playing with a toy like Lego, driving a familiar route, gardening, cooking, listening to music, or just gazing out the window. When you feel yourself getting tired or hitting a roadblock during deliberate practice, don’t keep pushing for too long. You want to be stretching yourself, not exhausting yourself. Instead, switch to one of those more relaxing activities

for at least five minutes. You'll likely come back to practice with new connections or at last feeling refreshed.

When you're practicing deliberately, truly practice. When you're recuperating, truly relax. No one can spend every waking hour on deliberate practice.

Deliberate practice involves constant feedback and measurement

"Deliberate practice is hard. It hurts. But it works. More of it equals better performance and tons of it equals great performance." —Geoff Colvin, *Talent Is Overrated*

Practicing something without knowing whether you are getting better is pointless. Yet that is what most of us do every day without thinking.

As we saw before, deliberate practice involves continuously stretching yourself to improve on weak areas of a skill. For that to work, practitioners require constant feedback about their current level of performance so they can identify what works for making it better. What gets measured gets managed. To engage in deliberate practice, you need a way of measuring the most instructive metrics related to your performance. Seeing how those metrics change is the sole way to know if practice is working or not. Top performers across fields tend to spend time examining their past performance with care to identify areas for improvement. For example, a tennis player might film themselves playing a match so they can go through the footage frame by frame afterward. This provides valuable feedback, because they can figure out what might have held them back during weaker moments. In fields such as sports and chess, measuring performance tends to be straightforward. In other areas such as business, measurements are harder to take, and there may be no established markers of success. The influence of random factors may also be stronger, making it less clear whether technique changes are actually having an influence or not. When you engage in deliberate practice, it's always important to be aware of how strongly correlated your practice and your performance are likely to be.

When measuring your performance, beware of vanity metrics. These are numbers that are easy to calculate and feel good to boost. But they don't actually move the needle towards the real improvements in performance that help you reach your goals. For example, let's say you're using deliberate practice to improve the skill of email marketing, as part of the wider goal of getting more customers for your business. The number of email subscribers is a vanity metric; the number of paying customers is a useful metric. It's completely possible to increase the former without a corresponding increase in the latter.

How to implement this: Identify the most significant metrics related to performance in your chosen skill and keep a record of them each time you practice. It's easy to fool yourself

without a clear record of how you're doing. You might want to break the skill down into a few different parts to measure it, but make sure you're not fixating on vanity metrics. Deliberate practice is most effective with the help of a coach or some kind of teacher *"The best teacher is not the one who knows most but the one who is most capable of reducing knowledge to that simple compound of the obvious and wonderful."* —H.L. Mencken (attributed)

Deliberate practice is most effective when conducted with some kind of coach who can give feedback, point out errors, suggest techniques for improvement, and provide vital motivation. Although mastering any skill requires a lot of time engaging in solitary practice, working with a coach at least some of the time is incredibly valuable. In some fields such as sports and music, it's common for a coach to be present all of the time. But most top performers benefit from a combination of coaching and solitary practice.

When we look at the lives of people who achieved great things, we often find that those who did so at a young age or in a shorter time than expected benefited from having fantastic teachers. For example, physicist Werner Heisenberg had the epiphany that led to the formulation of matrix mechanics a mere five years after commencing serious study of physics. But he no doubt benefited from the mentorship of Niels Bohr and Max Born, two of the foremost physicists at the time.

Even people at the most elite levels of performance across fields can benefit from specialist coaching. Engaging in something and teaching that thing are separate skills in themselves. The best practitioners are not always the best teachers because teaching is a skill in itself.

Ericsson explained that *"the best way to get past any barrier is to come at it from a different direction, which is one reason it is useful to work with a teacher or coach."* We often make the same mistakes again and again because we simply don't realize what we're doing. Our performance falls into ruts and we can't figure out why we're running into the same problem yet again.

A coach can see your performance from the outside, without the influence of overconfidence and other biases. They can identify your blind spots. They can help you interpret key metrics and feedback.

Ericsson went on to say that *"even the most motivated and intelligent student will advance more quickly under the tutelage of someone who knows the best order in which to learn things, who understands and can demonstrate the proper way to perform various skills, who can provide useful feedback, and who can devise practice activities designed to overcome particular weaknesses."* An experienced coach will have worked with many people on the same skill so they'll be able to advise on the best ways to structure practice. They'll know when you're just repeating what you find easy, and they'll be able to push you to the next level.

Teachers or coaches see what you miss and make you aware of where you're falling short. Geoff Colvin writes:

In some fields, especially intellectual ones such as the arts, sciences, and business, people may eventually become skilled enough to design their own practice. But anyone who thinks they've outgrown the benefits of a teacher's help should at least question that view. There's a reason why the world's best golfers still go to teachers.

But what if you don't have access to a coach? What if you don't have the means to hire one or one isn't available for your particular skill? In that case, it's still possible to apply the same principles that make a coach useful by yourself. Top performers across fields build the skill of metacognition, essentially making it possible for them to coach themselves.

Colvin explains:

The best performers observe themselves closely. They are in effect able to step outside themselves, monitor what is happening in their own minds, and ask how it's going.

Researchers call this metacognition—knowledge about your own knowledge, thinking

about your own thinking. Top performers do this much more systematically than others do; it's an established part of their routine.

...A critical part of self-evaluation is deciding what caused those errors. Average performers believe their errors were caused by factors outside their control: my opponent got lucky; the task was too hard; I just don't have the natural ability for this. Top performers, by contrast, believe they are responsible for their errors. Note that this is not just a difference of personality or attitude. Recall that the best performers have set highly specific, technique-based goals and strategies for themselves; they have thought through exactly how they intend to achieve what they want. So when something doesn't work, they can relate the failure to specific elements of their performance that may have misfired.

How to implement this: Don't expect the same teacher to suit you forever. We usually need different teachers as our skill level progresses because we outgrow them. One attribute of a good teacher is that they know when to tell a student to move on. As we reach expert levels of performance, we need teachers who are themselves experts. If they're always a step ahead, we can learn from their mistakes instead of making our own.

You get the best results from working with a coach if you show yourself to be receptive to constructive criticism, even if it's uncomfortable to hear. If you respond badly, you disincentivize them from telling you what's most useful to know. Top performers know the goal is to get better, not just to hear you're already great.

Deliberate practice requires intrinsic motivation

Persisting with deliberate practice despite its innate difficulty and discomfort requires a lot of motivation. But that motivation needs to be intrinsic, meaning that it comes from inside us because we find an activity enjoyable for its own sake. This is in contrast to extrinsic motivation, where we participate in an activity to gain an external reward or avoid a negative consequence. Yet another reason why rest is important for deliberate practice is because it helps sustain motivation.

Although deliberate practice can lead to external rewards for using a skill (such as winning a competition or getting a promotion), this should not be the sole reason for practicing it. Extrinsic motivation is unlikely to be enough to get us through the long period of struggle necessary to master a skill. Becoming proficient at anything means spending time failing repeatedly at it, during which there are few external rewards. But if we enjoy getting better for its own sake, we have more of a chance of persevering until our practice starts paying off. We can navigate obstacles because we want to see where the road might take us—the obstacles aren't roadblocks.

If you want to use deliberate practice to master a skill, you need to be willing to keep practicing it no matter what. Although brute force and rewarding yourself can be effective in the short run, it won't work forever. If you're planning to engage in deliberate practice to reach expert-level performance, make sure it's a prospect you feel excited about even if it won't always be fun.

Extrinsic motivation isn't always ineffective, however. People who engage in consistent, sustainable deliberate practice tend to be adept at knowing when and how they need to employ external incentives. It's important to reward yourself when you make progress in your practice and reflect on how far you've come, not just how far is left to go.

The need for intrinsic motivation is one reason why children who are pushed to develop a skill from a young age by their parents don't always end up reaching a high level of performance and often quit as soon as they can.

How to implement this: Make a list of the reasons you want to work on a skill and the benefits getting better at it might bring. Before you begin a deep practice session, reread the list to remind you of why you're bringing your full focus to something difficult. You could also list some of the benefits you've experienced from it in the past or include quotes from top performers in your field you find inspiring. It might feel cheesy, but it can provide a

powerful boost during particularly difficult practice moments. Try to focus on intrinsic reasons and benefits, such as feeling fulfilled.

Keep a “motivation diary” for one week (or longer if possible.) Try setting an alarm to go off every fifteen minutes during each practice session. When the alarm sounds, score your motivation level out of ten (or whichever scale you prefer.) At the end of the week, review your notes to look for any patterns. For example, you might find that you begin to feel demotivated once you’ve been practicing for more than an hour, or that you feel more motivated in the morning, or some other pattern. This information could be enlightening for planning future deliberate practice sessions, even if it may disrupt your focus at the time. Another method is to simply take notes each day, documenting your current level of motivation to work on your chosen skill. Pay attention to any recurring influences. For example, you might feel more motivated to improve your skill after speaking with a more proficient friend, but less motivated after a bad night’s sleep.

One potent option for sustaining motivation is to find someone who can be a reliable cheerleader for you. In an Ask Me Anything session for Farnam Street members, Tesla co-founder Marc Tarpenning explained that having a cofounder is vital for entrepreneurs because partnering with someone else helps sustain motivation. It’s rare that both founders feel demotivated on the same day. So if one is struggling, the other can provide the encouragement needed to stay resilient. Having someone to provide extrinsic motivation when you need it can help you persevere at deliberate practice. Your cheerleader doesn’t necessarily need to be working on the same skill themselves. They just need to understand your reasons and be willing to remind you of them when you start to doubt whether the hard work is worthwhile.

Deliberate practice takes time and can be a lifelong process

Although deliberate practice tends to result in much faster progress than normal practice, truly mastering a skill is a lifelong process. Reaching the top of a field can take years or even decades, depending on its competitiveness. As the bar for success in many areas keeps rising, more deliberate practice is required to stand out.

When we applaud the top people in any field, we often fail to appreciate that their success almost always came after many years of deliberate practice, which Robert Greene refers to in *Mastery* as “a largely self-directed apprenticeship that lasts some five to ten years [and] receives little attention because it does not contain stories of great achievement or discovery.” They may have ultimately benefited from a lucky break, but their extensive preparation meant they were ready for it. Great achievements tend to come later in life or even near the ends of careers. Those who succeeded young started very young.

Throughout Ericsson’s decades of research, he searched high and low for an example of a true prodigy: someone born with an innate, remarkable talent. He never found a single proven example. Instead, he discovered that people labeled as prodigies invariably put in enormous amounts of deliberate practice—they just often obscured it on purpose or started at a young age.

Although innate differences count when beginning to learn something (and people who begin with advantages may be more likely to persist), in the long run, deliberate practice always wins out.

David Shenk writes in *The Genius in All of Us*: “Short-term intensity cannot replace long-term commitment. Many crucial changes take place over long periods of time.

Physiologically, it’s impossible to become great overnight.”

According to psychologist John Hayes, creative genius tends to come after ten years of studying relevant knowledge and developing skills. Hayes referred to this as the “ten years of silence.” In a study of seventy-six composers with sufficient biographical data available listed in *The Lives of the Great Composers*, Hayes found they almost always created their first notable works (defined as being those for which at least five different recordings were available at the time) at least ten years after commencing a serious study of music. Just

three of the five hundred works Hayes included in his sample were composed after less than a decade of preparation—and those were produced in years eight or nine. In additional studies, Hayes found similar patterns for painters and poets.

Later research reinforces Hayes' findings, and any casual survey of the lives of people widely considered to be geniuses tends to show a similar pattern. Making a breakthrough takes time. When it seems like someone was an overnight success, there's almost always a long period of silent deliberate practice preceding it. Innate talents are just a starting point. If we want to master a skill, we need to commit to working on it for a lengthy period of time, likely with few rewards. While there are no assurances that with struggle comes reward, without it the odds are lower.

Not only do world-class performers spend a long time getting good at their core skill, those in creative fields tend to produce an enormous quantity of work before gaining recognition. For every piece of work we're familiar with, there are likely dozens or even hundreds of others few people remember or ever saw.

For example, British prime minister Winston Churchill was known for his masterful public speaking. One of his best-known speeches "We Shall Fight on the Beaches," given in June 1940, displayed the extent of his command of oration and helped build morale at the time. But it's hard to overstate how prolific Churchill was as a speaker, giving an estimated 3,000 speeches during his political career. For every speech—an average of one per week between 1900 and 1955—he used deliberate practice to prepare. He engaged in focused rehearsals in front of a mirror, taking notes as he went to inform modifications. Churchill also left nothing to chance, planning his pauses and movements in advance. As well as devising his own techniques for added impact, he memorized the works of some of history's most inspiring orators.

Although he doubtless began with a degree of innate talent (his father, Randolph Churchill, was also an admired orator), Churchill clearly used extensive deliberate practice to build upon it. While this impressive resume and history solidified his place on the throne of oratorical excellence, it's important to note that he wasn't a "born speaker"—in fact, he made many mistakes. And he learned from them. If you want to produce a masterpiece, you need to accept that you'll make a lot of less remarkable work first.

Deliberate practice requires intense focus

"You seldom improve much without giving the task your full attention." —Karl Anders Ericsson

The deeper we focus during deliberate practice sessions, the more we get out of them. Intense focus allows us to increase skills and break through plateaus. Developing your attention span can have a huge impact on your life. When asked about his success, Charlie Munger once said, *"I succeeded because I have a long attention span."*

The authors of *The Game Before the Game* write, *"If you can pay attention for only five minutes in practice, then take a break every five minutes. If you can pay attention for only twenty balls, don't hit fifty. To be able to practice longer and maintain the quality of the practice, train yourself to pay attention for longer periods of time....Productive practice is about how present you can stay with your intention and is measured in the quality of the experience as opposed to the quantity of time used."*

A benefit of getting constant feedback is that it shows you what moves the needle towards improved performance and what is just running in place. Certain practice activities can feel good without having any impact. Top performers prioritize knowing what to prioritize. They always start with the most important thing because anything else is a distraction.

Intense focus is a multiplier of everything else. Keeping an eye on key metrics enables top performers to identify and systematically remove distractions from their lives. To be the best, you need to focus on both the micro and macro level. You need to pay full attention to what you're doing in the current practice sessions, and you need to know how it fits into

the bigger picture of your desired trajectory. Deliberate practice is part of the exploit phase of selecting opportunities.

As the authors of the *International Handbook of Research in Professional and Practice-Based Learning* write, “*Practicing the right things is at the core of the theory of deliberate practice.*”

How to implement this: Put the big rocks in first. You can do anything, but you can’t do everything. Figure out which practice activities have the biggest influence on your performance and plan to engage in those first before you even consider activities that offer marginal gains.

Deliberate practice leverages the spacing effect

One reason why consistent deliberate practice sessions over the course of years are more effective than longer sessions for a shorter period of time relates to the spacing effect. We can’t approach learning a skill through deliberate practice in the same way we quite likely approached studying for tests in school. If we better understand how our minds work, we can use them in the optimal way for learning. By leveraging the spacing effect, we can encode valuable knowledge related to our particular skill for life during practice sessions. Memory mastery comes from repeated exposure to the same material. The spacing effect refers to how we are better able to recall information and concepts if we learn them in multiple sessions with increasingly large intervals between them. The most effective way to learn new information is through spaced repetition. It works for learning almost anything, and research has provided robust evidence of its efficacy for people of all ages—and even for animals.

Spaced repetition is also satisfying because it keeps us on the edge of our abilities (which, as we saw earlier, is a core element of deliberate practice.) Spaced sessions allow us to invest less total time to memorize than one single session, whereas we might get bored while going over the same material again and again in a single session. Of course, when we’re bored we pay less and less attention. The authors of *Focused Determination* put it this way:

There is also minimal variation in the way the material is presented to the brain when it is repeatedly visited over a short time. This tends to decrease our learning. In contrast, when repetition learning takes place over a longer period, it is more likely that the materials are presented differently. We have to retrieve the previously learned information from memory and hence reinforce it. All of this leads us to become more interested in the content and therefore more receptive to learning it.

We simply cannot practice something once and expect it to stick.

By engaging in deliberate practice on a regular basis, even if each practice session is short, we leverage the power of the spacing effect. Once we learn something through spaced repetition, it actually sticks with us. After a certain point, we may only need to revisit it every few years to keep our knowledge fresh. Even if we seem to forget something between repetitions, it later proves easier to relearn.

How to implement this: Forget about cramming. Each time you’re learning a new component of a skill, make a schedule for when you’ll review it. Typical systems involve going over information after an hour, then a day, then every other day, then weekly, then fortnightly, then monthly, then every six months, then yearly. Guess correctly and the information moves to the next level and is reviewed less often. Guess incorrectly and it moves down a level and is reviewed more often.

The history of deliberate practice

Karl Anders Ericsson: The expert on expertise

"Learning isn't a way of reaching one's potential but rather a way of developing it." —Karl Anders Ericsson, *Peak*

The concept of deliberate practice is attributed to Florida State University psychologist Karl Anders Ericsson, who along with his collaborators performed pioneering research in the field of expert performance. Ericsson spent decades seeking to answer the question of what it takes to become really good at something difficult. His research often focused on medicine, music, and sports.

Ericsson's interest in expert performance kicked off in the late 1970s, when he began working with psychologist Bill Chase at Carnegie Mellon University to study short-term memory. Together, they began a series of experiments to see how many random digits it's possible to memorize after hearing them once. Ericsson and Chase used an undergrad named Steve Faloan as their guinea pig. For a few hours each week, they read out numbers and Faloan repeated as many as he could recall.

Although the experiment might sound dull, they uncovered something intriguing. In a 1982 paper entitled "Exceptional Memory," Ericsson and Chase summarized their findings. Previously, researchers believed the average person could hold just seven random digits in their short-term memory. Yet with careful practice, Faloan began to remember more and more numbers. At his peak and after 200 hours of practice, he could recall 82 digits. To assess if this was a fluke, Ericsson tried the same with a friend, Dario Donatelli. Five years later, Donatelli could recall 113 digits. Both he and Faloan went far beyond what seemed to be an immovable ceiling on human performance and blew past existing world records. The experience of seeing two people who started off with ordinary memories enhance their capabilities in such a drastic way inspired Ericsson to further study the effects of practice on skills. Could it be that extraordinary abilities came from extraordinary practice, not just innate ability?

Through his studies of expert performers in a range of fields, Ericsson concluded they practiced their skills in a fundamentally different way than amateur practitioners. Ericsson described this kind of practice as "deliberate" due to its methodical, hyper-conscious nature. He argued that experts become experts largely as a result of the way they practice. They may benefit from innate advantages, but their talents themselves are not innate. Ericsson also believed that the standards in many additional fields could be improved far beyond their current level if practitioners employed the principles of deliberate practice. Indeed, many fields have seen remarkable increases in their standards for high performance over time. Today, high-schoolers manage athletic feats that were once Olympic level and children play music once considered world-class. This is possible because of better training and knowledge of what it takes to be the best. The more we improve how we train, the more we expand our range of possible performance.

In 2016, Ericsson published *Peak: Secrets from the New Science of Expertise*, a popular science book condensing his learnings from thirty years of research. He also co-edited the 2006 *Cambridge Handbook of Expertise and Expert Performance*.

Malcolm Gladwell: The 10,000 hour rule

The widespread awareness of Ericsson's work outside the scientific community is in part a result of Malcolm Gladwell's 2008 book, *Outliers: The Story of Success*. In the book, Gladwell attributed unusual success in different fields to a mixture of lucky factors (such as when or where a person was born) and around 10,000 hours of practice. He based this figure on research, including Ericsson's, that suggested top performers tended to have put in about that amount of time before reaching peak performance.

Gladwell showed how the success of Bill Gates, the Beatles, and other outstanding performers is not so much to do with what they are like but rather where they come from.

"The people who stand before kings may look like they did it all by themselves," Gladwell

writes. *“But in fact they are invariably the beneficiaries of hidden advantages and extraordinary opportunities and cultural legacies that allow them to learn and work hard and make sense of the world in ways others cannot.”*

The so-called “10,000 hours rule” caught on. It’s a catchy idea, and many people took it to mean that anyone can master anything if they just put the time in. Ericsson himself disputed Gladwell’s representations of his research, which led to the widespread belief that the time someone spends practicing predicts their success, without emphasizing the quality of their practice.

Although the backlash against Gladwell’s calculation has arguably been exaggerated, it’s important to stress that research into deliberate practice emphasizes quality of practice, not quantity. It’s all too possible to spend 10,000 hours engaging in a skill without serious improvements. For example, most of us spend hours per day typing, yet we don’t see continuous improvements in speed and quality because we’re not using deliberate practice.

The useful takeaway from the “10,000 hours rule” is simply that it takes a lot of work to become the best. There’s no magic number of practice sessions, and everyone’s path will look different. Just because successful people in a given field have spent around 10,000 hours practicing their key skill, that doesn’t mean every person who practices that skill for 10,000 hours will become successful.

The limitations and downsides of deliberate practice

Part of us wants to believe expert performance is something innate and magical so we can excuse ourselves from hard work. The other part of us wants to believe that it’s something earned through blood, sweat, and tears—that we too could achieve amazing performance, if only we could devote ourselves to something.

Deliberate practice, in reality, is far more complex and nuanced than many people would have you believe. It’s not a panacea, and it won’t solve all of your work- and art-related problems. Let’s take a look at some of the limitations of deliberate practice.

First of all, deliberate practice is a necessary but insufficient part of becoming a world-class performer. You can’t rise to the top without it. But it’s not enough on its own to be the absolute best in any field. Once you reach higher echelons for any skill, everyone is engaging in a lot of deliberate practice.

If you’re aiming at expertise or just really good performance, deliberate practice will most likely get you there. But the higher you rise, the more luck and randomness end up mattering. However much you engage in deliberate practice, you can’t control the chance events (good or bad) that dictate a great deal of life.

When we look at the lives of top performers, they often benefited from specific backgrounds or opportunities, in addition to engaging in deliberate practice. For example, if you’re trying to become a champion chess player, it’s a big boost if your mother was a champion chess player. Not only will you have potential genetic advantages, you’ll have also likely grown up hearing about chess, been encouraged to practice it from a young age, and have someone to turn to for advice.

Seeing as it takes years of consistent deliberate practice to master a skill, people who begin early in life have an advantage over those who start later on. That doesn’t mean you can’t become exceptional at something you discover well into adulthood (just look at [Julia Child](#) or check out the book *Guitar Zero*). But it does mean that people who begin deliberate practice as kids are more likely to enjoy the success that makes it possible to keep committing to it. If you’re trying to master a skill while also having to work an unrelated job, care for your family, and deal with the other myriad responsibilities of adult life, you likely will have less room for it than a ten-year-old.

People who discover they want to master a skill or are encouraged to do so by others early in life have an advantage. Once the opportunity for practice is in place, the prospects of

high achievement take off. And if practice is denied or diminished, no amount of talent is going to get you there.

In addition to lucky circumstances, high performers benefit from a combination of deliberate practice and innate talents or physical advantages. However much you practice, certain physical limitations are insurmountable. For example, if you're 165 centimeters tall, you're unlikely to become a professional basketball player. There are some physical abilities, such as particular kinds of flexibility, that can only be developed at a young age when a person's skeletal structure is still forming. It's important to be realistic about your starting point and be aware of any limitations. But that doesn't mean you can't develop workarounds or even use them to your advantage.

Another downside of deliberate practice is that the level of focus it requires can mean practitioners miss out on other parts of life. Top performers often devote almost every waking hour to practice, recuperation from practice, and support activities. For example, a professional dancer might spend several hours a day on deliberate practice with all of the remaining hours going toward sleep, low-impact exercise, stretching, preparing nutritious food, icing his feet, and so on. There is enormous satisfaction in the flow states produced by deliberate practice, but practitioners can absolutely miss out on other sources of happiness, such as spending time with friends.

Deliberate practice is part of the exploit phase of new opportunities. Yet sometimes we can end up having too much grit. We can keep persevering with the skill we're practicing right now, remaining overly passionate, past the point where it serves us. We can wear ourselves out or get hurt or fail to realize when it's no longer worth practicing a skill. For example, a new technology might mean our skill is no longer valuable. If we keep on deliberate practicing due to sunk costs, we'll be unlikely to see many long-term benefits from it. A crucial skill in life is knowing when to pivot. Focusing too much on our goals can blind us to risks.

In some fields, expertise is hard to quantify or measure, which makes it less clear how to structure practice. There may be no single target to hit or universal rule for what improves performance.

A final limitation to keep in mind is that, as Ericsson explained, "*the cognitive and physical changes caused by training require upkeep. Stop training and they go away.*" If someone can't practice for a period of time, such as due to an injury or having a child, they're likely to see the skills they developed through deliberate practice deteriorate.

Summary

Deliberate practice isn't everything, but if you want to keep improving at a skill or overcome a plateau, you'll benefit from incorporating the principles mentioned in this article. To recap:

- Deliberate practice means practicing with a clear awareness of the specific components of a skill we're aiming to improve and exactly how to improve them.
- The more we engage in deliberate practice, the greater our capabilities become.
- Our minds and bodies are far more malleable than we usually realize.
- Deliberate practice is structured and methodical.
- Deliberate practice is challenging because it involves constantly pushing yourself out of your comfort zone.
- Deliberate practice requires constant feedback and measurement of informative metrics—not vanity metrics.

- Deliberate practice works best with the help of a teacher or coach.
- Continuing deliberate practice requires a great deal of intrinsic motivation.
- Deliberate practice requires constant, intense focus.
- Deliberate practice leverages the spacing effect—meaning a consistent commitment over time is crucial.
- If you're content with your current level of skill or just doing something for fun, you don't necessarily need to engage in deliberate practice
- Deliberate practice is best suited to pursuits where you're actively aiming for a high level of performance or to break beyond some kind of supposed limit.

Step 151-Review, Reflection, Review And Accountability

A. Listen and Follow The Following Book:

1. **How We Think By John Dewey**

B. Analyse: If I win or Lose, I should be excited. If I win or loss, the process should be exactly the same. You have to go back and look:

1. **Good Habits, Virtues, Skills and improvement by 1%.**
2. **Bad Habits, Virtues, Skills and decline by 1%.**
3. **Find the finds I done well and worked.**
4. **Figured out how and why did they work well.**
5. **How can I make them again.**
6. **Find the things I failed. How and why it did not work well.**
7. **Find the things I could do better.**
8. **Find, Study and Analyse my weakness and Strengths. Work hard on my weaknesses. Perfect my strengths and work hard on my strengths.**
9. **Study and Analyse the strength and weakness of the opponent or competitors and work with your weakness to their strengths.**
10. **What are unfinished tasks and what action.**

C. Did I Take Responsibility?

1. **Pay Attention to Details.**
2. **Acknowledge and fix your mistakes.**
3. **Develop proactive approach.**
4. **Offer solution instead of complaints.**
5. **Accept Criticism.**
6. **Show Focus.**

D. Did I take Accountability?

- 1. Take Responsibility for the loss and analyse the mistakes I made. Analyse what to change to overcome those mistakes and be better at your craft or any area in life.**
- 2. They're completely focused on taking responsibility and taking charge, whether they're competing in sports or managing a family or running a business or driving a bus; they decide how to get the job done, and then they do whatever is necessary to make it happen.'".**
- 3. Want to know a true sign of a Cleaner? He feels no pressure when he screws up and has no problem admitting when he's wrong and shouldering the blame: When a Cooler makes a mistake, he'll give you a lot of excuses but no solutions. When a Closer makes a mistake, he finds someone else to blame. When a Cleaner makes a mistake, he can look you in the eye and say, 'I Screw up.'".**
- 4. Made a mistake? Don't sugar-coat it. Don't look for excuses. Don't blame other people. Own it.**
- 5. Develop the confidence to say when you've screwed up – people will respect you for it.**
- 6. Next time you're making an excuse, catch yourself. Admit it to yourself that it was your fault. Take responsibility for it. Own it.**

E. Track The Hours Spent For That Week For Different Task.

F. Use Weekly Review To Celebrate Good and Bad Weeks.

G. Do it Correctly, Slowly, Patiently, Methodically, Logically, Take It Time and Do Not Rush Process..

Step 152 - Improvement

Improvement

- A. What First to Improve in Steps of Performance.
- B. What to Change for better Performance.
- C. What First to Improve in Steps of Performance.
- D. What to Change for better Performance.
- E. Ask yourself: Where are you now?
- F. Ask yourself: Where do you want to be instead?
- G. Ask yourself: What are you willing to do to get there?
- H. Make a plan to get there.
- I. Act on it.
- J. Look at the improvement over the long period of time, and decide the steps I will take to improve. Look at the improvement as marathon, where you step by step improving.
- K. Take One Step at the time to move forward.
- L. Write Down the Notes on Improvement.
- M. No Shortcut. Mastery does not tolerate shortcuts. Shortcuts exist to get better results with the same amount of pain/effort. It can neither scale nor work in the long term. The only way to go beyond your limitations is to do more, and better
- N. Do It Correctly, Slowly, Patiently, Methodically, Logically Take It Time and Do Not Rush Process.

Step 153 - Feedback System In Place

1. Feedback System In Place.

- I. Arrange a feedback, that you will get consistently and reliably.
- II. This could be hired a coach or friends who are honest.
- III. Iteration (repetition process) is fundamental basis of all improvement.

Step 154-Repeat

1. Repeat.

- I. Next Step is to Repeat (steps 1-126) for every single module in learning plan until completed every single one.**

- A. Record Strategy, Tactics and Plan.**
- B. Preparation.**
- C. Examine.**
- D. Listen Strategy, Tactics and Plan.**
- E. Performance.**
- F. Improvement.**
- G. Record Reflection and Review.**
- H. Listen Recorded Reflection, Review.**
- I. Record Improvement.**
- J. Listen Improvement.**
- K. Performance.**
- L. Record Reflection and Review.**
- M. Listen Recorded Reflection, Review.**

Step 155-Letting The World Do The Work For You

1. Listen and Apply book
 - I. This Explains Everything_ Deep, Beautiful, and Elegant Theories of How the World Works
2. The world never tells you that you're wrong; it only gives you outcomes.
3. Don't force. Don't resist. Have a beginner's mind. Let the world teach you.
4. **Reality will do a lot of the work for us if we simply align with it.** Most of the time we're simply adding friction because we want the world to work in the way we think it should.
5. If you don't see the world the way it is, you'll think it works in a way that it doesn't and make terrible mistakes. The key to getting what you want out of life is to identify how the world works and align yourself accordingly. This is hard because we think the world should work the way we see it. The word "should" is important. Because we think the world should work in a way that it doesn't, our approach is suboptimal. What the pupil must learn, if he learns anything at all, is that the world will do most of the work for you, provided you cooperate with it by identifying how it really works and aligning with those realities. If we do not let the world teach us, it teaches us a lesson. Joseph Tussman
6. When an outcome is not what you want it to be, things get tough. You can ignore the result and continue to think that you're right. This protects your ego. It also carries the risk of your continuing to believe something that isn't true. Alternatively, you can calibrate your believability on the subject at hand by lowering the odds that you're right. For example, maybe you gave yourself an 85 out of 100 for the ability to hold a firm opinion on this subject, and now you lower your score to 75. If the world continues to provide undesirable outcomes, eventually you get the hint and change your beliefs. Finally, you can give up your opinions and just respond to the world as it is. This option is the hardest.
7. You do not create the way the world works, you can only align yourself with it. It takes a lot of work to align ourselves with reality. When we don't get the outcome we're seeking, the last place we look is inside ourselves. Instead, we blame others or circumstances. If you want to align yourself with reality, you have to work at it and care

about it. There are two keys to aligning yourself with how the world really works: accepting feedback and stopping bargaining.

- I. We let people, not results, guide our behavior. The world tries to tell us when we don't see it the way it is. The problem is we don't listen to the world. Instead, we let others tell us what's right and wrong, what works, and what doesn't. Common actions get common results. Most of our actions come from others. We want what they want. Even worse, we employ the same actions to get it. This isn't always wrong. If you're just starting, the quickest path to average is to copy. If you want better results than average, you're going to have to iterate. Doing something different means we might look like a fool, and we do not want to look like a fool. Iterating means trying something new, it means you might fail. Show me a person who's afraid to look bad, and I'll show you a person you can beat every time. If we do what everyone else is doing, we're going to get the same results that everyone else is getting. Different results demand different actions. If you can't really fail, you can't really succeed. Let results, not popularity, determine your actions. If you're doing something that doesn't get you the results you want, try something new. If you're doing something that seems to work, keep doing it. Consistently repeat successful actions.
- II. Bargaining with the world doesn't work. A lot of otherwise smart people know what they're doing isn't getting the results they want, but because they think the world *should* work in a way that it doesn't, they keep repeating them hoping for different results. If you are this person, see it for what it is, and change your actions. The feedback from the world is often painful. Often, it is this very pain that causes us to no longer delude ourselves with how the world should work and accept how it does work. If you can learn to accept the world for how it is, before suffering, you'll go faster and further. Outcome over ego. If you think you know how the world works but you're doing something that gets suboptimal results because it *should* work a different way, you don't really know how the world works. Rational people take feedback from the world. If you want to know how someone sees the world, look at their actions. In the end, it's all your fault. You are accountable for your outcomes. When you take responsibility for your outcomes, you naturally accept feedback from reality. When you get feedback from reality, you adjust your behavior.
- III. As Per Kobe Bryant statement: Trivial things should not be taken your attention. The attentions should be focused on things that is very important. Anything

outside of the most important things in life, you should not have time for. You Should love the challenge in life, and always be curious, if you can be at the top , as these greats in that area. Always focus on one thing and not multiple things, this gives an edge and advantage over other people, who focusing on multiple things in life. The World Becomes a library to you, to be better at your craft.: Everything you see whether TV show I saw, Books, Journals, I read, whether discussion, debate I listen, people I talk to. Everything was done to try to learn to become better at the craft your focusing. When you have this point of you, then the world becomes your library to help you to become better at the craft.

- IV. Have the best work ethic on daily basis. This is everyday process, and try to figure it out, the strengths and weaknesses of my position and opposing person position.
- V. Always look at the reality of the situation, and do not let the emotion cloud the situation and the execution. Always be in the present and the moment.
- VI. If you understand the world as it really is, not as you'd wish it to be, you will begin to make better decisions almost immediately. Once you start making better decisions the results compound. Better initial decisions free up your time, reduce your stress, allowing you to spend more time with your family and leave your competition in the dust.
- VII. How can we best understand the world as it is? Acquiring knowledge can be a very daunting task. If you think of the mind as a toolbox, we're only as good as the tools at our disposal. A carpenter doesn't show up to work with an empty toolbox. Not only do they want as many tools in their toolbox as possible, but they want to know how to use them. Having more tools and the knowledge of how to use them means they can tackle more problems. Try as we might, we cannot build a house with only a hammer. If you're a knowledge worker, you're a carpenter. But your tools aren't bought at a store and they don't come in a red box that you carry around. Mental tools are the big ideas from multiple disciplines, and we store them in our mind. And if we have a lot of tools and the knowledge required to wield them properly, we can start to synthesize how the world works and make better decisions when confronted with problems.
- VIII. This is how we understand and deal with reality. The tools you put into your toolbox are Mental Models. Mental models are a framework for understanding how the world really works. They help you grasp new ideas quickly, identify patterns before anyone else and shift your perspective with ease. Mental Models

allow us to make better decisions, scramble out of bad situations, and think critically. If you want to understand reality you must look at a problem in multiple dimensions — how could it be otherwise? Getting to this level of understanding requires having a lot of tools and knowing how to use them. You knew there was a hitch right? We need to change our fast-food diet of information consumption and adopt the healthier diet of knowledge that changes slowly over time. While changing diets isn't easy, it can be incredibly rewarding: more time, less stress, and being better at your job. The costs, however, are short term pain for long-term gain. You must change how you think.

- IX. 2nd Order Thinking. One example of a model we can immediately conceptualize and use to improve our ability to make better decisions is something we can borrow from ecology called second-order thinking. The simple way to conceptualize this is to ask yourself "If I do X, what will happen *after* that?". I sum this up using the ecologist Garrett Hardin's simple question: "And then what?" A lot of people forget about higher order effects — second and third-order effects or higher. I've been in a lot of meetings where decisions are made and very few people think to the second level, let alone the third. Rather, what typically happens is called first conclusion bias. The brain shuts down and stops thinking at the first idea that comes to mind that seems to address the problem as you understand it. We don't often realize that our first thoughts are usually not even our own thoughts. They usually belong to someone else. We understand the sound-byte but we haven't done the hard work of real thinking. After we reach the first conclusion, our minds often shut down. We don't seek evidence that would contradict our conclusion. We don't ask ourselves what the likely result of this solution would be — we don't ask ourselves "And then what?" We don't ask what other solutions might be even *more* optimal. For example, consider a hypothetical organization that decides to change their incentive systems. They come up with a costly new system that requires substantial changes to the current system. Only they don't consider (or even understand) the problems that the *new* system is likely to create. It's possible they've created more problems than they've solved — only now there are *different* problems they must put their head down to solve. Optically, they "reorganize their incentive programs," but practically, they've simply expended energy to stay in place. Another, perhaps more complicated, example is when a salesman comes into a company and offers you a software program he claims will lower your operating costs and increase your profits. He's

got all these beautiful charts on how much more competitive you'll be and how it will improve everything. This is exactly what you need because your compensation is based on increasing profits. You're sold. Then second-order thinking kicks in and you dare to ask how much of those cost savings are going to go to you and how much will eventually end up benefits enjoyed by customers? To a large extent, that depends on the business you're in. However, you can be damn sure the salesman is now knocking on your competitor's door and telling them you just bought their product and if they want to remain competitive they better purchase it too. Eventually, you all have the new software and no one is truly better off. Thus, in the manner of a crowd of people standing on their tip-toes at a parade, all competitors spend the money but none of them win: The salesman wins and the customer wins. We know, thanks to people like Garrett Hardin, Howard Marks, Charlie Munger, Peter Kaufman, and disciplines like ecology, that there are second and third-order effects. This is how the world really works. It just isn't always a comfortable reality. Understanding how the world works isn't easy and it shouldn't be. It's hard work. If it were easy, everyone would do it. And it's not for everyone. Sometimes, if your goal is to maximize utility, you should focus on getting very, very good in a narrow area and becoming an expert, accepting that you will make many mistakes outside of that domain. But for most, it's extremely helpful to understand the forces at play outside of their narrow area of expertise. Because when you think about it, how could reality be anything other than a synthesis of multiple factors? How could it possibly be otherwise?

- X. When our mental models line up with reality, they help us avoid problems. However, they also cause problems when they don't line up with reality as we think something that isn't true.
- XI. We must be open to other perspectives if we truly want to understand the results of our actions. Despite feeling that we've got all the information, if we're on the ship, the fish in the ocean has more he can share. The second flaw is ego. Many of us tend to have too much invested in our opinions of ourselves to see the world's feedback—the feedback we need to update our beliefs about reality. This creates a profound ignorance that keeps us banging our head against the wall over and over again. Our inability to learn from the world because of our ego happens for many reasons, but two are worth mentioning here. First, we're so afraid about what others will say about us that we fail to put our ideas out there and subject them to criticism. This way we can always be right. Second, if we do

put our ideas out there and they are criticized, our ego steps in to protect us. We become invested in defending instead of upgrading our ideas. The third flaw is distance. The further we are from the results of our decisions, the easier it is to keep our current views rather than update them. When you put your hand on a hot stove, you quickly learn the natural consequence. You pay the price for your mistakes. Since you are a pain avoiding creature, you update your view. Before you touch another stove, you check to see if it's hot. But you don't just learn a micro lesson that applies in one situation. Instead, you draw a general abstraction, one that tells you to check before touching anything that could potentially be hot. Organizations over a certain size often remove us from the direct consequences of our decisions. When we make decisions that other people carry out, we are one or more levels removed and may not immediately be able to update our understanding.

Step 156- Spend 5k-10k Hours

1. Spend 5k-10k Hours.

- I. Iterate (repetition process) for 5k-10k hours.
- II. There are not shortcuts.
- III. If you want to be good at anything you need to spend 10k hours trial and error, until you master.
- IV. Do It Correctly, Slowly, Patiently, Methodically, Logically Take It Time and Do Not Rush Process.

PART 21: Deep Work and Prediction

Step 157 - Prediction Books

1. **Listen, Follow And Apply Rules of Reading Part 1 to 18, before looking Prediction.**
2. **Listen, Follow and Apply the following Books.**
 - **Financial Analysis, Modelling, and Forecasting Technique**
 - **Financial Planning & Analysis and Performance Management.**
 - **Predictably, The hidden Forces That Shape Our Decision.**
 - **Predictive Analytics For Dummies**
 - **Predictive Analytics.**
 - **Reading People_ How to Understand People and Predict Their Behavior- -Anytime, Anyplace.**
 - **Sports Performance Measurement and Analytics_ The Science of Assessing Performance, Predicting Future Outcomes, Interpreting Statistical Models.**
 - **Thinking_ The New Science of Decision-Making, Problem-Solving, and Prediction.**

Step 158-Steps In Predicting

So How Can You Improve Your Own Prediction Skills?

1. Watch Videos of the Person who I rolling, Sparing, and see the movements and the steps they are taking in order to take one position or the other.

I. See the opponent favorite attack Tactics:

- Check The steps they are taking?
- What angles do they take?
- What are weaknesses of their in the attack?
- How can I explore their weakness in my defence?

II. See the opponent favorite defence tactics

- Check The steps they are taking?
- What angles do they take?
- What are weaknesses of their defence?
- How can I explore their weakness in my Defence?

2. Watch Live rolling of the person who I rolling, Sparing, and see the movements and the steps they are taking in order to take one position or the other.

I. See the opponent favorite attack Tactics:

- Check The steps they are taking?
- What angles do they take?
- What are weaknesses of their in the attack?
- How can I explore their weakness in my defence?

II. See the opponent favorite defence tactics

- Check The steps they are taking?
- What angles do they take?
- What are weaknesses of their defence?
- How can I explore their weakness in my Defence?

3. Recognise Patterns- Pay attention the following:

I. Where are the hands?

II. Where are the feet?

III. How the weight is distributed?

IV. Where the back?

V. Where is the whole body moves toward?

4. **Know All The Facts.** Analysis starts with data. It's more than data, but it starts with data. You need to be rooted in the real world, and you need to be rigorous. Before you start anything, you need to gather as much data as possible, and then crunch it, which can mean combining data points, but often means discarding data points as well.
5. **Live And Breathe Your Space.** The other key tool in analysis is the understanding of your market, and just as important, your primary research, which by and large means talking to people. You need to be embedded in your space's social and intellectual networks, and you need to talk to the people who are smarter than you, embedded in the space, and learn from them. This creates a virtuous circle: talking to smart people makes you smarter, which makes smart people want to talk with you.
6. **Forget Everything I've Just Said.** Data is fine, even necessary. Primary research is fine, even necessary. But there's another element which is just as necessary (and most often lacking). It's that special something. It's often dubbed insight. It's seeing the trend that nobody else is seeing. This is a question that has obsessed me. I don't know that I've cracked it, but I think I've found a method that works for me, and that is: every once in a while, forget everything you know. Every once in a while, you have to look at what you're obsessed about like you don't know anything about it. Clear your mind. Think about other stuff. It sounds silly, but what matters is putting yourself in a frame of mind where you're looking at the situation from a new angle, and realizing that by only focusing yourself on your area of expertise you will miss things.
7. **Establish a Base Rate.** Compare. Establish the "base rate," the typical historical frequency or severity of the outcome you are trying to forecast, by picking a reference class of similar past events. Very few situations are unique; think deeply enough about the instance at hand, and you will likely discover a set of historical precedents for it. Instead of guessing how stocks will do if interest rates rise by one percentage point, for instance, look at the full sample of all such past interest-rate increases, take the average of subsequent stock performance and use that as your base-rate assumption.
8. **Be Specific.** Try to flush your ignorance out into the open: Don't just say, "I think emerging-markets stocks are cheap right now." Instead, say "There is an 80% probability that emerging-markets stocks will go up at least 25% in the next 12

months.” When significant new information comes in, adjust your forecast incrementally.

9. Consider the Opposite. Invert. Consider the opposite and ask what information you would need if you were trying to make a case that emerging-markets stocks will go down at least 25% in the next 12 months. Then seek it out, absorb it and test whether you need to revise your original forecast.
10. Cast a Wide Net. Find a variety of sources for news and analysis, varying widely in their viewpoints, vested interests and geographic origin. Discount the sources that use the self-reinforcing language of overconfidence: Words like “furthermore,” “clearly” and “certain” or “impossible.” Heed most closely those sources that admit uncertainty with words like “however,” “but,” and “on the other hand.”
11. Measure Everything. Record in detail the reasoning behind your forecasts. When you turn out to be right, don’t just celebrate; check your records to see whether you were right for the reasons you predicted or whether you just got lucky. When you turn out to be wrong, compare this error to the other times you were mistaken, looking for patterns to correct. If you don’t measure every meaningful aspect of your forecasts, you will never improve.

Step 159 - Have I done The Work

1. When Give Opinion on Anything, Do Not Be so Angry and Mean to Others.
2. People Need To Stop Doing By Coming Unprepared To Give Opinion On Any Subject, Without Having Good Idea Of The Literature, and Arguments Written on Topic and Theme Available To Them. The people coming unprepared and not doing any Hard Work To Have an Opinion On The Subject or Topic. When People Coming Overconfidence, which could be resulting in Lack of Preparation, Which Could Lead That Your Position can be Destroyed with Ease. They simply won't do the work required. It's easy to come home, sit on the couch, watch TV, and zone out until bedtime rolls around. But that's not going to help you get smarter.
 - A. People Who Do Not Put The Required Work: The first thing they always do is tell you what they think. When someone has an opinion about everything, they want to share it with you. They often tout stats and research as if they had an imaginary checklist of facts they need to be able to rattle off to establish themselves as an expert in a field they actually know very little about. Because they have an opinion on everything, they are quick to judge others – for their lack of opinions, for their lack of knowledge, for their lack of outrage, and the list goes on.
 - B. People who have opinions about everything barf so much noise that it's hard to find the signal. Your brain has to work overtime to figure out if they did the work to come up with their opinions themselves or if they're simply regurgitating some oped in a newspaper. Over time, opinionated people also end up in their own prisons and they try to take you with them.
 - C. The problem comes from how we see the world. Our opinions are often rooted in how we think the world should work, according to our morals, values, and principles. If we see the world through the lens of our opinions, much of what happens will not agree with us. This is feedback, and how we respond to this feedback is key.

3. How to Get Smarter Read. A lot. Warren Buffett says, "I just sit in my office and read all day." What does that mean? He estimates that he spends 80% of his working day reading and thinking. When asked how to get smarter, Buffett once held up stacks of paper and said, "Read 500 pages like this every week. That's how knowledge builds up, like compound interest." All of us can build our knowledge, but most of us won't put in the effort. "Go to bed smarter than when you woke up."
4. How Long Does it Take To Prepare:
 - A. Depend on the topic and opponent, and how much he's written.
 - B. If the opponent nothing published, then there was very little preparation to be made because I simply didn't know what to expect.
 - C. On the other hand, if the opponent has published lots of written work and have some videos. Read and what his written and videos and prepare the summaries articles, videos, and have sense where he is coming from. This can take Weeks or Months.

5. Before Preparation. The difference between the people who do the work and the people who just reel off memorized opinions is huge. When you do the work, you can answer the next question. You know when to follow the rules and when they'll get you in trouble. When I did my postgraduate I was surrounded by people who could answer the test questions. They got good grades — actually, they got *great* grades but an odd thing happened after school: a lot of those people couldn't apply their knowledge to problems they hadn't seen before. They were chauffeurs — they knew the memorized answer. They couldn't answer the next question. We're all chauffeurs in some aspects of our lives. This is why understanding your circle of competence is so critical to living a rational life.

I. Circle of Competence:

A. **Circle Of Competence**-Understanding my Circle of Competence helps to avoid problems, identify opportunities for improvement and learn from Others. Circle of Competence is simple: Each of us, through experience or study, has built up useful knowledge on certain areas of the world. Some areas are understood by most of us, while some areas require a lot more specialty to evaluate. For example, most of us have a basic understanding of the economics of a restaurant: You rent or buy space, spend money to outfit the place and then hire employees to seat, serve, cook, and clean. (And, if you don't want to do it yourself, manage.) From there, it's a matter of generating enough traffic and setting the appropriate prices to generate a profit on the food and drinks you serve—after all of your operating expenses have been paid. Though the cuisine, atmosphere, and price points will vary by restaurant, they all have to follow the same economic formula. That basic knowledge, along with some understanding of accounting and a little bit of study, would enable one to evaluate and invest in any number of restaurants and restaurant chains, public or private. It's not all that complicated. Far more important is to honestly define what we do know and stick to those areas. Our circle of competence can be widened, but only slowly and over time. Mistakes are most often made when straying from this discipline. Where should we devote our limited time in life, to achieve the most success? So, the simple takeaway here is clear. If you want to improve your odds of success in life and business, then define the perimeter of your circle of competence, and operate inside. Over time, work to expand that circle

but never fool yourself about where it stands today, and never be afraid to say “I don’t know.”

II. Two Type of Knowledge: The Max Planck and Chauffeur Test

A. The Two Types of Knowledge: The Max Planck and Chauffeur Test: How to distinguish between the two types of knowledge: real knowledge and pretend knowledge.

- The first type of knowledge is real. It can’t be bought. It can’t be copied. If you want real knowledge you need to earn it. One is Planck knowledge, the people who really know. They’ve paid the dues, they have the aptitude. You are going to have the problem in your life of getting the responsibility into the people with the Planck knowledge and away from the people with the chauffeur knowledge. Real knowledge comes when people do the work. The problem is that it’s difficult to separate the two. This is the Batesian Mimicry problem. One way to tease out the difference between Planck and chauffeur knowledge is to ask them why.
- The second type of knowledge is copied. On the surface you know the answer but you lack the understanding to show your work. Then we’ve got chauffeur knowledge. They’ve learned the talk. They may have a big head of hair, they may have fine temper in the voice, they’ll make a hell of an impression. But in the end, all they have is chauffeur knowledge. I think I’ve just described practically every politician in the United States. We have the people who don’t do the work — they pretend. While they’ve learned to put on a good show, they lack understanding. They can’t answer questions that don’t rely on memorization. They can’t explain things without using jargon or vague terms. They have no idea how things interact. They can’t predict the consequences. The problem is that it’s difficult to separate the two. This is the Batesian Mimicry problem. One way to tease out the difference between Planck and chauffeur knowledge is to ask them why.
- How To Distinguish Real Knowledge and Fake Knowledge. With journalists, it is more difficult. Some have acquired true knowledge.

Often they are veteran reporters who have specialized for years in a clearly defined area. They make a serious effort to understand the complexity of a subject and to communicate it. They tend to write long articles that highlight a variety of cases and exceptions. The majority of journalists, however, fall into the category of chauffeur. They conjure up articles off the tops of their heads or, rather, from Google searches. Their texts are one-sided, short, and— often as compensation for their patchy knowledge. The same superficiality is present in business. The larger a company, the more the CEO is expected to possess “star quality.” Dedication, solemnity, and reliability are undervalued, at least at the top. Too often shareholders and business journalists seem to believe that showmanship will deliver better results, which is obviously not the case. One way to guard against this is to understand your circle of competence. Dobelli concludes with some advice worth taking to heart. Be on the lookout for chauffeur knowledge. Do not confuse the company spokesperson, the ringmaster, the newscaster, the schmoozer, the verbiage vendor, or the cliché generator with those who possess true knowledge. How do you recognize the difference? There is a clear indicator: True experts recognize the limits of what they know and what they do not know. If they find themselves outside their circle of competence, they keep quiet or simply say, “I don’t know.” This they utter unapologetically, even with a certain pride. From chauffeurs, we hear every line except this.

III. Batesian Mimicry Problem. Batesian Mimicry: Why Copycats Are Successful.

Mimic and the Real Thing:

- A. "There's two kinds of snakes you come across. There's the Texas Coral Snake, and the Mexican Milk Snake, and they both look exactly alike. The Texas Coral Snake is dangerous, it's venomous, it can kill you in a minute. The Mexican Milk Snake can't do anything to you; it's an impostor." How is it that these two look alike? It's due to a phenomenon called Batesian Mimicry.
- B. In the 1850s, the naturalist Henry Walter Bates found a certain set of butterflies who were clearly *not* of the same species but whose wings looked almost the same to the naked eye. After thinking it over, Bates eventually figured out what was going on: While the butterflies which were toxic to potential predators (the "models") were able to operate freely and relatively unmolested, there had also developed a "mimic" population of butterflies which wasn't toxic at all, yet still went untouched! In fact, biologists eventually figured out that the more toxic and dangerous the "model" was and the more frequently they appeared in the local population, the easier it was for its "mimics" to get by! Predators simply wouldn't take the risk of mixing up the two. If there aren't as many "models" around or they aren't that dangerous, the mimics have a harder time.
- C. This is a wonderful model, and in the practical world we live in, a similar phenomenon abounds: Copycats or "pretenders to the throne" are often very effective, very convincing "mimics" of the true champions. They dress the part, they talk the talk, and they know what buttons to push. But in the end, they are merely chauffeurs. We see a very Batesian effect at work: The more impressive the "model," the more effective its mimics can be in convincing people they too are impressive, and in all the same ways. But for every Warren Buffett (just one by our count), there has been many "future" Warren Buffett's. For every Steve Jobs, there have been many "next" Steve Jobs'. In fact, sometimes even just *appearances* can be quite convincing: now-disgraced Theranos founder Elizabeth Holmes was very fond of wearing a very Steve Jobsian black turtleneck outfit. Because they can be very convincing, we must be wise enough to watch out for Batesian mimicry

— even in ourselves. This brings up an interesting, at times paradoxical, question: Who can best tell the difference between a Coral Snake and its Mimics? The Coral Snake itself. The real thing knows a fake. It's worth taking the time to work on learning all the big ideas you can find, not just the ones you want to learn. In that search, you'll find a host of big winners you didn't even know existed.

6. Preparation:

- A. While we all hold an opinion on almost everything. Have I do the work required to have an opinion on any Subject? Never allow myself to have an opinion on anything that I don't know the other side's argument better than they do. The work required to have an opinion is very hard part, have I avoid it?
 - I. I have to do the reading.
 - II. I have to talk to competent people and understand their arguments.
 - III. Never try to be biased toward any of the side, but question both side of the argument.
 - IV. Do not support any side, until all the facts are put out there, clear and obvious.
 - V. Once known all the facts then analyse both sides of the argument like William Lane Craig.
 - VI. I have to think about the key variables and how they interact over time.
 - VII. I have to listen and chase down arguments that run counter to your views.
 - VIII. I have to think about how you might be fooling yourself.
 - IX. I have to see the issue from multiple perspectives.
 - X. I have to think.
 - XI. I need to become your most intelligent critic and have the intellectual honesty to kill some of your best-loved ideas.
 - XII. Be honest with yourself and open minded. ANALYSE both side of the argument logically and see which is true logically. Means has the clear terms, premises are true, and conclusion follows from premises.
 - XIII. Never say your opinion about anything that requires the analysis of the arguments and facts. Work very bery hard to have an opinion about anything.
 - XIV. Listen very carefully other side and use ancient method *state the opposition argument in my own words and ask him/her if the argument I

stated in my own words represents correctly their argument and if I UNDERSTOOD Correctly their arguments.

XV. Never use cheap shots to win argument, like logical fallacies.

XVI. Debate and discussion is not about just win at any cost, but let other person to think about your arguments and engage with them. Second reason never use in discussion cheap shots toward other person, but be civil. Third reason is win the debate and discussion. Fourth is find the truth.

B. For Affirmative and Negative Case:

- I. Read, analyse, Research, Syntopicon and Investigate Published Work.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of My own Arguments
- II. Read Opponents Books, Articles, Newspapers, Blogs. Reading Published work. What objections he would raise against the topic and prepare the responses for each of these points.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of opponent Arguments.
- III. Watch Video. Watching Videos of the opponent. What objections he would raise against the topic and prepare the responses for each of these points.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of My own Arguments.
- IV. Listen The recording that the opposition made, in which he addresses these issues.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of My own Arguments.
- V. Talk with People who are students in his class, who can tell me, privately, insights into his thinking and character.
- VI. If that sounds like a lot of work, just say, “I don’t have an opinion on that; why don’t you tell me how you got to have such a firm one? It sounds like I could learn something.”
- VII. Another way to get smarter, outside of reading, is to surround yourself with people who are not afraid to challenge your ideas. “Develop into a lifelong self-learner through voracious reading; cultivate curiosity and strive to become a little wiser every day.”

7. Compound Knowledge- Are The Resources I will Choose Concentrating On the Expiring Information or Compound Knowledge?

- I. Are on the Resources providing expiring information?
 - C. Will you care about what you're reading in a month? In a year? In five years?
 - D. Are you focused enough on the same thing to build cumulative knowledge or are you too spread out?
 - E. What do you spend time on that's likely to change in the next few years? What's not likely to change?
 - F. What would need to happen for you to stop outsourcing organisation of information to the computer?
- II. Signs of The Information in the resources are expiring
 - A. First, it's marketed to you.
 - B. Second, lacking details and nuance, it's easily digestible. This is why it's commonly telling you what happened, not why it happened or under what conditions it might happen again
 - C. Third, it won't be relevant in a month or a year. Expiring information is one reason I stopped reading most news. It's a false map.
- III. While most of us focus on consuming information that we won't care about next month, let alone next year, focus on knowledge and companies that change very, very slowly or not at all. And because the information he was learning changed slowly he could compound his knowledge over time.
- IV. Doing his own thinking and vacuums up the details. When we don't think for ourselves it's easy to put the blame on someone else, to "pass the buck" so to speak.
- V. When we consume information that doesn't expire or expires slowly; is very detailed; and we spend time thinking about it not passing the buck, we can match patterns. This is how you learn to see what other people are missing. The longer you do this, the more advantage you get.
- VI. Just like the rest of us, Buffett's dependent on information and knowledge to make great decisions. Unlike most of us, he has a great memory—perhaps because he's not trying to outsource his memory or thinking to others.
- VII. A lot of what the snowball is about the concept of learning, and creating, and the advantage of having the information and knowing it. When I came here today one

of the things that I was thinking is that what you do is so much at the intersection, because retrieving information is different from having it already in your head.

VIII. What you do is different. You work on manipulating how you use the information.

In fact, Warren Buffett and Charlie Munger have the files in their head. That's why they aren't really out there googling all the time looking for, trying to look stuff up, because they already know it.

IX. I think a lot of the work that you do here is helpful to the ordinary person, but Warren Buffett or Charlie Munger don't need it. At the same time, the lesson that they have, which is that learning yourself, making yourself as smart as you can is extremely valid, and not just relying on a library where you can look something up all the time, because a lot of times when you need to make a decision, and you need 50 pieces of information, you need to know it then.

8. The Art of Anticipation of Objections.

- A. Analyse My Arguments, and Scrutinise The arguments by using Rules of Reading.
- B. Analyse the arguments of the opponent. Scrutinise Their arguments by using Rules of Reading.
- C. Analyse My own arguments. Scrutinise My own arguments, and the potential Loopholes in the argument by Use Rules of Reading.
- D. Use Think, Logic, Strategem, Thinking models.
- E. Write.
- F. Prepare The responses to anticipated objections that, I think the opponent will bring up.
- G. Be intellectually Prepared. This means That I need to know my arguments, so well, that nothing new can surprise me. I would also invest lots of time in knowing and know better opposite side arguments. I would read both side of the arguments, and work Hard on analysing the arguments and evidence of both sides. Doing the work required to hold an opinion means you can argue against yourself better than others can. Only then can you say, "I can hold this view because I can't find anyone else who can argue better against my view." Great thinkers, like Charles Darwin, did the work. And it's one of the biggest reasons he's buried at Westminster Abbey. While we all hold an opinion on almost everything. Have I do the work required to have an opinion on any Subject? Never allow myself to have an opinion on anything that I don't know the other side's argument better than they do. The work required to have an opinion is very hard part, have I avoid it? If that sounds like a lot of work, just say, "I don't have an opinion on that; why don't you tell me how you got to have such a firm one? It sounds like I could learn something."
- H. Doing the work required to hold an opinion means you can argue against yourself better than others can. Only then can you say, "I can hold this view because I can't find anyone else who can argue better against my view." Great thinkers, like Charles Darwin, did the work. And it's one of the biggest reasons he's buried at Westminster Abbey.
- I. Doing the work counteracts our natural desire to seek out only information that confirms what we believe we know. When Darwin encountered opinions or facts that ran contrary to his ideas, he endeavored not only to listen but also not to rest

until he could either argue better than his challengers or understand how the fact fit. Darwin did the work. It's wasn't easy, but that's the point.

- J. Have the best work ethic on daily basis. This is everyday process, and try to figure it out, the strengths and weaknesses of my position and opposing person position, This leads to the True Confidence.
- K. As Per Kobe Bryant statement: Trivial things should not be taken your attention. The attentions should be focused on things that is very important. Anything outside of the most important things in life, you should not have time for. You Should love the challenge in life, and always be curious, if you can be at the top , as these greats in that area. Always focus on one thing and not multiple things, this gives an edge and advantage over other people, who focusing on multiple things in life. The World Becomes a library to you, to be better at your craft.: Everything you see whether TV show I saw, Books, Journals, I read, whether discussion, debate I listen, people I talk to. Everything was done to try to learn to become better at the craft your focusing. When you have this point of view, then the world becomes your library to help you to become better at the craft.
- L. I Always need to ask myself: Have I done the work required to have an opinion on any Subject? Never allow myself to have an opinion on anything that I don't know the other side's argument better than they do. The work required to have an opinion is very hard part, have I avoid it? If that sounds like a lot of work, just say, "I don't have an opinion on that; why don't you tell me how you got to have such a firm one? It sounds like I could learn something."
- M. I might need to Suspend my judgement and tell them that I do not have an opinion on this specific Topic.
- N. Never Under Prepare, but Vastly Over Prepare for the Opponent and their arguments and responses
- O. Spend years in preparation, take debate class at the college or university. You need to participate in debates. You need to have mock debates, where someone play role of your opponent, and then you respond to them. You need to do reading and learn how to flow the debates. How to construct affirmative case and negative case. You need to take time to prepare and have enormous preparation.
- P. Memorize the arguments for my case

9. When Dialogue, Discussion, Debate Takes A Place.

A. As Affirmative Speaker, you need to present Prima Facie Case for proposition that is under debate. Prima Facie Case will be one that will establish the truth of proposition you are defending. If I am defending proposition that God Exist, I will want to give 3-5 arguments leading to that Conclusion, that God Exists, and then I will lay those out with great clarity in my opening speech, and say this is the groundwork for the debate. I am not interested in talking about other issues for example if Christianity bad for society Then, I come back to those in every speech over and over again. The goal is to make opponent argue on your grounds. You do not go over to his grounds, and let your audience forget, your affirmative case, rather you reorganise opponent speech, so that you answer his objections in so far as they reply to your arguments, so you may answer them in a very different order than he gave them, because you will be seeing for example: now what answer or response did he have to the cosmological argument, I see two basic responses and then you deal with them.

- Make Briefs, where I have suitable objection, and then have two or three responses to those objections.
- Use The Brief During Exchange with the Opponent. File these Briefs into Folders, and spread These Manila Folders out in front of me on Desk, When I am interacting with the Opponent. Once the opponent Rises his point I just pull These briefs from these folders and never have to think on my feet because I am completely prepared. Key is never have to think on the feet to be so well prepared, that I would have my responses ready for anything he brings up.
- Quote Peer Review Scientific Articles on the topic in support the conclusions.

B. Take Notes While the Opposition is speaking:

- How To Take Notes- Flow Chart. By Taking Notes, I am sure that I am responding to my opponent's arguments and everything he brings up.

- I. Make 11-12 Columns on the Pad. Prepare the left column in advance of the communication, debate. The Left Column needs to be filled in, if you starting first. If not, then leave left column as blank.
- II. First Left Hand Column Are My Arguments.
- III. Second Left Hand Column are Opposition Arguments and Responses to My arguments.
- IV. Third Left Column are My Responses to the Opponent responses.
- V. Fourth Left Hand Column are My Rebuttal.
- VI. Fifth Left Hand Column are Opponent Rebuttal.
- VII. Sixth Left Hand Column are my Responses to the Opponent rebuttal.
- VIII. Seventh Left Hand Column is the Final My Rebuttal.
- IX. Eight Left Hand Column is The opponent Rebuttal.
- X. Ninth Left Hand Column is my closing statements.
- XI. Tenth Left Hand Column is the opponent closing statements.
- XII. Eleventh Left Hand Column is the Cross Examination.
 - My Answer.
 - Opponent Answer.
 - My response to the response of the opponent.

C. Always Remind the audience what are your three to five arguments and what are the responses of the opponent, if any to your arguments.

D. Always allow the opponent allow to lay out his argument without interruption.

E. Take the opponent arguments and put in my own words and correctly represent their argument carefully without misrepresentation.

F. Be Honest.

G. Be Open Minded.

H. Always from Your side be honest and rigorous exchange of arguments and counter Arguments from which me and opponent would benefit.

I. One of good technique is whenever you can quote an opponent against himself, this is powerful device. Have the manuscript, point to the footnote, cite the book, and the quotation and have the page number.

J. Never Take Cheap Shots at the Opponent.

- K. Encourage not just trust someone say so, but demand published peer reviewed articles in support of the positions that one take
- L. Always look at the reality of the situation, and do not let the emotion cloud the situation and the execution. Always be in the present and the moment.

Step 160-Letting The World Do The Work For You

1. Listen and Apply book
 - I. This Explains Everything_ Deep, Beautiful, and Elegant Theories of How the World Works
2. The world never tells you that you're wrong; it only gives you outcomes.
3. Don't force. Don't resist. Have a beginner's mind. Let the world teach you.
4. **Reality will do a lot of the work for us if we simply align with it.** Most of the time we're simply adding friction because we want the world to work in the way we think it should.
5. If you don't see the world the way it is, you'll think it works in a way that it doesn't and make terrible mistakes. The key to getting what you want out of life is to identify how the world works and align yourself accordingly. This is hard because we think the world should work the way we see it. The word "should" is important. Because we think the world should work in a way that it doesn't, our approach is suboptimal. What the pupil must learn, if he learns anything at all, is that the world will do most of the work for you, provided you cooperate with it by identifying how it really works and aligning with those realities. If we do not let the world teach us, it teaches us a lesson. Joseph Tussman
6. When an outcome is not what you want it to be, things get tough. You can ignore the result and continue to think that you're right. This protects your ego. It also carries the risk of your continuing to believe something that isn't true. Alternatively, you can calibrate your believability on the subject at hand by lowering the odds that you're right. For example, maybe you gave yourself an 85 out of 100 for the ability to hold a firm opinion on this subject, and now you lower your score to 75. If the world continues to provide undesirable outcomes, eventually you get the hint and change your beliefs. Finally, you can give up your opinions and just respond to the world as it is. This option is the hardest.
7. You do not create the way the world works, you can only align yourself with it. It takes a lot of work to align ourselves with reality. When we don't get the outcome we're seeking, the last place we look is inside ourselves. Instead, we blame others or circumstances. If you want to align yourself with reality, you have to work at it and care

about it. There are two keys to aligning yourself with how the world really works: accepting feedback and stopping bargaining.

- I. We let people, not results, guide our behavior. The world tries to tell us when we don't see it the way it is. The problem is we don't listen to the world. Instead, we let others tell us what's right and wrong, what works, and what doesn't. Common actions get common results. Most of our actions come from others. We want what they want. Even worse, we employ the same actions to get it. This isn't always wrong. If you're just starting, the quickest path to average is to copy. If you want better results than average, you're going to have to iterate. Doing something different means we might look like a fool, and we do not want to look like a fool. Iterating means trying something new, it means you might fail. Show me a person who's afraid to look bad, and I'll show you a person you can beat every time. If we do what everyone else is doing, we're going to get the same results that everyone else is getting. Different results demand different actions. If you can't really fail, you can't really succeed. Let results, not popularity, determine your actions. If you're doing something that doesn't get you the results you want, try something new. If you're doing something that seems to work, keep doing it. Consistently repeat successful actions.
- II. Bargaining with the world doesn't work. A lot of otherwise smart people know what they're doing isn't getting the results they want, but because they think the world *should* work in a way that it doesn't, they keep repeating them hoping for different results. If you are this person, see it for what it is, and change your actions. The feedback from the world is often painful. Often, it is this very pain that causes us to no longer delude ourselves with how the world should work and accept how it does work. If you can learn to accept the world for how it is, before suffering, you'll go faster and further. Outcome over ego. If you think you know how the world works but you're doing something that gets suboptimal results because it *should* work a different way, you don't really know how the world works. Rational people take feedback from the world. If you want to know how someone sees the world, look at their actions. In the end, it's all your fault. You are accountable for your outcomes. When you take responsibility for your outcomes, you naturally accept feedback from reality. When you get feedback from reality, you adjust your behavior.
- III. As Per Kobe Bryant statement: Trivial things should not be taken your attention. The attentions should be focused on things that is very important. Anything

outside of the most important things in life, you should not have time for. You Should love the challenge in life, and always be curious, if you can be at the top , as these greats in that area. Always focus on one thing and not multiple things, this gives an edge and advantage over other people, who focusing on multiple things in life. The World Becomes a library to you, to be better at your craft.: Everything you see whether TV show I saw, Books, Journals, I read, whether discussion, debate I listen, people I talk to. Everything was done to try to learn to become better at the craft your focusing. When you have this point of you, then the world becomes your library to help you to become better at the craft.

- IV. Have the best work ethic on daily basis. This is everyday process, and try to figure it out, the strengths and weaknesses of my position and opposing person position.
- V. Always look at the reality of the situation, and do not let the emotion cloud the situation and the execution. Always be in the present and the moment.
- VI. If you understand the world as it really is, not as you'd wish it to be, you will begin to make better decisions almost immediately. Once you start making better decisions the results compound. Better initial decisions free up your time, reduce your stress, allowing you to spend more time with your family and leave your competition in the dust.
- VII. How can we best understand the world as it is? Acquiring knowledge can be a very daunting task. If you think of the mind as a toolbox, we're only as good as the tools at our disposal. A carpenter doesn't show up to work with an empty toolbox. Not only do they want as many tools in their toolbox as possible, but they want to know how to use them. Having more tools and the knowledge of how to use them means they can tackle more problems. Try as we might, we cannot build a house with only a hammer. If you're a knowledge worker, you're a carpenter. But your tools aren't bought at a store and they don't come in a red box that you carry around. Mental tools are the big ideas from multiple disciplines, and we store them in our mind. And if we have a lot of tools and the knowledge required to wield them properly, we can start to synthesize how the world works and make better decisions when confronted with problems.
- VIII. This is how we understand and deal with reality. The tools you put into your toolbox are Mental Models. Mental models are a framework for understanding how the world really works. They help you grasp new ideas quickly, identify patterns before anyone else and shift your perspective with ease. Mental Models

allow us to make better decisions, scramble out of bad situations, and think critically. If you want to understand reality you must look at a problem in multiple dimensions — how could it be otherwise? Getting to this level of understanding requires having a lot of tools and knowing how to use them. You knew there was a hitch right? We need to change our fast-food diet of information consumption and adopt the healthier diet of knowledge that changes slowly over time. While changing diets isn't easy, it can be incredibly rewarding: more time, less stress, and being better at your job. The costs, however, are short term pain for long-term gain. You must change how you think.

- IX. 2nd Order Thinking. One example of a model we can immediately conceptualize and use to improve our ability to make better decisions is something we can borrow from ecology called second-order thinking. The simple way to conceptualize this is to ask yourself "If I do X, what will happen *after* that?". I sum this up using the ecologist Garrett Hardin's simple question: "And then what?" A lot of people forget about higher order effects — second and third-order effects or higher. I've been in a lot of meetings where decisions are made and very few people think to the second level, let alone the third. Rather, what typically happens is called first conclusion bias. The brain shuts down and stops thinking at the first idea that comes to mind that seems to address the problem as you understand it. We don't often realize that our first thoughts are usually not even our own thoughts. They usually belong to someone else. We understand the sound-byte but we haven't done the hard work of real thinking. After we reach the first conclusion, our minds often shut down. We don't seek evidence that would contradict our conclusion. We don't ask ourselves what the likely result of this solution would be — we don't ask ourselves "And then what?" We don't ask what other solutions might be even *more* optimal. For example, consider a hypothetical organization that decides to change their incentive systems. They come up with a costly new system that requires substantial changes to the current system. Only they don't consider (or even understand) the problems that the *new* system is likely to create. It's possible they've created more problems than they've solved — only now there are *different* problems they must put their head down to solve. Optically, they "reorganize their incentive programs," but practically, they've simply expended energy to stay in place. Another, perhaps more complicated, example is when a salesman comes into a company and offers you a software program he claims will lower your operating costs and increase your profits. He's

got all these beautiful charts on how much more competitive you'll be and how it will improve everything. This is exactly what you need because your compensation is based on increasing profits. You're sold. Then second-order thinking kicks in and you dare to ask how much of those cost savings are going to go to you and how much will eventually end up benefits enjoyed by customers? To a large extent, that depends on the business you're in. However, you can be damn sure the salesman is now knocking on your competitor's door and telling them you just bought their product and if they want to remain competitive they better purchase it too. Eventually, you all have the new software and no one is truly better off. Thus, in the manner of a crowd of people standing on their tip-toes at a parade, all competitors spend the money but none of them win: The salesman wins and the customer wins. We know, thanks to people like Garrett Hardin, Howard Marks, Charlie Munger, Peter Kaufman, and disciplines like ecology, that there are second and third-order effects. This is how the world really works. It just isn't always a comfortable reality. Understanding how the world works isn't easy and it shouldn't be. It's hard work. If it were easy, everyone would do it. And it's not for everyone. Sometimes, if your goal is to maximize utility, you should focus on getting very, very good in a narrow area and becoming an expert, accepting that you will make many mistakes outside of that domain. But for most, it's extremely helpful to understand the forces at play outside of their narrow area of expertise. Because when you think about it, how could reality be anything other than a synthesis of multiple factors? How could it possibly be otherwise?

- X. When our mental models line up with reality, they help us avoid problems. However, they also cause problems when they don't line up with reality as we think something that isn't true.
- XI. We must be open to other perspectives if we truly want to understand the results of our actions. Despite feeling that we've got all the information, if we're on the ship, the fish in the ocean has more he can share. The second flaw is ego. Many of us tend to have too much invested in our opinions of ourselves to see the world's feedback—the feedback we need to update our beliefs about reality. This creates a profound ignorance that keeps us banging our head against the wall over and over again. Our inability to learn from the world because of our ego happens for many reasons, but two are worth mentioning here. First, we're so afraid about what others will say about us that we fail to put our ideas out there and subject them to criticism. This way we can always be right. Second, if we do

put our ideas out there and they are criticized, our ego steps in to protect us. We become invested in defending instead of upgrading our ideas. The third flaw is distance. The further we are from the results of our decisions, the easier it is to keep our current views rather than update them. When you put your hand on a hot stove, you quickly learn the natural consequence. You pay the price for your mistakes. Since you are a pain avoiding creature, you update your view. Before you touch another stove, you check to see if it's hot. But you don't just learn a micro lesson that applies in one situation. Instead, you draw a general abstraction, one that tells you to check before touching anything that could potentially be hot. Organizations over a certain size often remove us from the direct consequences of our decisions. When we make decisions that other people carry out, we are one or more levels removed and may not immediately be able to update our understanding.

PART 22: Deep Work and Feynman Technique

Step 161-Feynman Technique

Feynman Technique

I. Choose a Concept, Idea, topic to Learn. Select a Topic You are interested in learning about and write it at the top of the blank page in the Notebook or Paper.

- A. Choose your topics carefully: Not everything that you study suits this technique. Usually abstract complex ideas are best understood by Feynman technique but ideas that are evidence-based/observational might not really be suited for this.
- B. Selecting a concept to study compels you to be intentional about what you don't know. It also forces you to choose a topic that's small enough that it could reasonably fit onto one or several pages.
- C. **You face what you don't know.** By writing a topic down on a blank page, you acknowledge you're starting from scratch or at least filling in some blanks. In doing so, take the initial step in the process.
- D. **You need to be specific.** Given the accumulated knowledge in the universe, most of us know nothing about most things! Writing down explicitly what you don't know provides you with a starting point.

II. Use It For Real.

- A. Use it for real: perfectly suitable for weekly tech-talks, lectures, paper-reading, Study, Bible Study, Sermon or any type of study, deep work and deep study sessions.

III. Study The Topic By Reading, Listening, Watching and Communicating.

- A. You have to start small. You really only have a page (or a few) to fill up with information. You can't fit everything there is to know about "Evolutionary Science" or "Microeconomics" or "Psychology" on a page. Instead work on smaller more defined concepts or what might reliably be found on a midterm or final exam.
- B. Fully understand the complex topic first: Don't begin the learning process by explaining it before you actually understand it. Retention methods such as Feynman technique, active-recall and spaced repetition are for solidifying information that you already understand. Trying to solidify an information before you understand it might end up encoding wrong interpretation of a topic.
- C. Actually put the time and effort: Once you have selected the correct set of topics, make sure you actually spend the time and effort to go through the entirety of the techniques. Feynman technique is great for having a basic framework of the topic inside your head with the details chopped off. It's important to get a very clear picture of the basics in your head right - the details can be filled in later.
- D. Make it your own.
 - Start with not knowing.
 - Ask 'why?'. ask why $x=y$. or why does music has 12 notes and not 14.
 - Study the story of what you are studying. E.g. study what was physics before Quantum theory. Why QT was needed, who were the people involved in developing the QT and how it changed the world.
- E. Take Notes On the Topic From Study.
- F. Consolidate the information concisely onto a flashcard or some other place for long term retention: Once we really understand a topic to be able to explain the core principles without having to use jargon, we should hold onto that understanding. Unfortunately, a large portion of that information that we just gathered is lost within first 48 hours after learning. So note it down somewhere before you lose it. Optimise for spaced-repetition for next sessions.
- G. Don't write notes on notes: Life is short.
- H. Cornell Notes.
 - How Will I Take Notes and Cornell Note Take Method Pages 79-82.

IV. Simplify The Topic For Myself First.

- A. Simplify your explanation so that YOU understand it. As long as the explanation is not simple enough for YOU to understand, spend more hours to break it down to basic, bare-bone, core ideas.
- B. Avoid jargon and complexity. The simpler the explanation, the more likely you are to remember it.
- C. Only Use Simple Words. The words a child would understand.
- D. Anyone can make a subject complicated but only someone who understands can make it simple. Jargon hides our lack of understanding. When forced to write out an idea from start to finish in simple language, you discover where you struggle, where it doesn't quite make sense, where you get frustrated, where you don't really understand as well as you thought. Only by identifying gaps in your knowledge can you fill them.
- E. But true understanding requires a more active process like *teaching*. Start out by formally teaching yourself. Write out a summary in your own words without looking at your notes. Or explain it to yourself out loud. Then take it to the next level by teaching other people. Teaching also initiates a feedback loop, where critique or questions can help us learn and sharpen our thinking.
- F. **It makes it harder to trick yourself.** When you have to truly explain something, whether through writing or aloud, you encounter the holes in your reasoning and the white spaces in your knowledge. Think of writing and teaching as a process to *obtain understanding*, not something you do once you already understand.

V. Reflect, Refine, and Simplify

- A. Only when you can explain the subject in simple terms do you understand it.
- B. Simple is beautiful.
- C. Review your notes to make sure you didn't mistakenly borrow any jargon or gloss over anything complicated.
- D. Read it out loud as if to a child. If the explanation isn't simple enough or sounds confusing, that's a good indication that you need to reflect and refine.
- E. Go back to the source material, reviewing the parts you don't quite understand yet.
- F. Repeat until you have a simple explanation.

VI. Return to the source material if you get stuck. Go back to whatever you're learning from – a book, lecture notes, Journal, Newspaper, podcast or any other resource and source – and fill the gaps in your knowledge.

A. Step 1- Use The Chosen Rules of Reading Method For Analysis, Syntopicon, Research, Investigative Journalism or Mixed Method and Follow Each Steps Of The Method Until Finish All Steps, While Re-listen Lectures, Read Books or Lecture Notes 1-100 Times For Each Step.

B. Step 2- Following Rules of Reading Methods:

C. VERY VERY FAST Reading- Skimming. Pages 47-51.

D. VERY FAST READING- Entertainment.

I. Method 1-Speed Reading. FAST Reading. Pages 59-64.

E. FAST READING: Methods for Basic Knowledge For Deep Work or Bible Study.

I. Method 1-Survey, Question, Read, Recite, Record, Reflect (SQR4). Pages 66-67.

II. Method 2-Use 80/20 Principle For Reading. Pages 68.

III. Method 3-Preview, Question, Read, Summary,Test (PQRST). Page 69.

IV. Method 4-Flip Through Pages and Analyse. Page 70.

V. Method 5-Devotional Bible Study by Using Devotional Books. Pages 71-72.

VI. Method 6-Devotional Bible Read. Pages 73-74.

F. Deep Work, Deep Study, Bible Study or Any Book- SLOW Reading- Complex Text.

- I. Method 1-Chapter Summary Method. Pages 143-147.**
- II. Method 2-Character Quality Method. Pages 148-160.**
- III. Method 3-Thematic Method. Pages 161-163.**
- IV. Method 4-Biographical Method. Pages 164-176.**
- V. Method 5-Topical Method. Pages 177-180.**
- VI. Method 6-Word Study Method. Pages 181-189.**
- VII. Method 7-Book Background Method. Pages 190-194.**

G. VERY VERY SLOW READING- COMPLEX TEXT. Deep Work, Shallow Work, Bible Study, Analysis of Text, Research, Investigative Journalism, Investigation and Syntopicon, Mixed Method.

- I. Method 21- How To Read A Book By Mortimer Adler Various edition Pages 341.**
- II. Method 22-How To Read A Book For Various Books. Pages 342-600.**
- III. Method 23- Syntopicon Pages 601-642.**
- IV. Method 24-The Craft of Research. Pages 644-882.**
- V. Method 25-Research Books can Be Used. Pages 883-897.**
- VI. Method 26-Investigative Journalism. Pages 898-923.**
- VII. Method 27-Mixed Methods of Rules of Reading. Pages 924-942.**

- A. Learning should be iterative. More often than not, learning something challenging takes several attempts. With the Feynman Technique, returning to the source material is an explicit part of the learning process. When gaps in our knowledge arise and our explanations aren't quite right, revisiting our primary and secondary sources can help solidify what we're learning.
- B. Getting it right will likely take several iterations. That's a good thing; the more you refine your explanations, the more your understanding will deepen. Learning becomes an iterative process. Rather than viewing learning as one-and-done, this step gives you permission to continuously refresh your knowledge.
- C. You're actively engaged. Using sources to polish our own explanations and models is an active process. When we learn passively, committing details to memory is more challenging. When we're actively part of creating our own summaries and reasoning, drawing intentionally from original information to fill our blind spots, we can more readily commit knowledge to our long-term memory.
- D. You expand your knowledge base. Paradoxically, the more we learn, the more *our capacity* to learn increases. Looking through a chapter of a textbook might feel like a different language the first time around. The second time it becomes more clear. The third time, with a strong base already, we pick up nuances we couldn't have possibly seen before.

VIII.Simplify your explanations and create analogies. Streamline your notes and explanation, further clarifying the topic until it seems obvious. Additionally, think of analogies that feel intuitive.

- A. Every field of study has its own specialised terms. While it may be important to know them, it's also important to not confuse knowing jargon with knowing concepts. The Feynman Technique involves simplifying our initial explanations and refining our understanding through simple analogies..Why this step works:
- B. Simplicity is a proxy for understanding. It's easy enough to commit terms to memory, and repeat them back when prompted. But memorisation is not understanding. When we can't rely on big words that make us sound smart, we have to distill what we truly know to the most basic form. This is where true understanding takes place.
- C. Analogies are easier to recall and explain. When you understand a challenging concept, analogies allow you to create a short-hand for recalling it quickly and explaining it to others clearly. Learning material often provides ready-made analogies for us. For example, we all probably have "the mitochondria are the powerhouse of the cell" burned into our collective memories. However, pushing ourselves to create our own analogies is even more powerful than regurgitating a borrowed one that we may not actually understand.

IX. Teach it to yourself or someone else. Write everything you know about a topic out as if you were explaining it to yourself. Alternately, actually teach it to someone else.

- A. Classic learning mistake is reading an article or textbook and considering our learning complete. In reality, reading is not understanding. We might even take notes, essentially transcribing a resource's sentences into our notebooks. We often nod to ourselves, thinking we've grasped a subject. After all, *we've taken notes*.
- B. Remove any jargon or complexity.
- C. Only Use Simple Words. The words a child would understand.
- D. Anyone can make a subject complicated but only someone who understands can make it simple. Jargon hides our lack of understanding. When forced to write out an idea from start to finish in simple language, you discover where you struggle ... where it doesn't quite make sense ... where you get frustrated ... where you don't really understand as well as you thought. Only by identifying gaps in your knowledge can you fill them.
- E. But true understanding requires a more active process like *teaching*. Start out by formally teaching yourself. Write out a summary in your own words without looking at your notes. Or explain it to yourself out loud. Then take it to the next level by teaching other people. Teaching also initiates a feedback loop, where critique or questions can help us learn and sharpen our thinking.
- F. **It makes it harder to trick yourself.** When you have to truly explain something, whether through writing or aloud, you encounter the holes in your reasoning and the white spaces in your knowledge. Think of writing and teaching as a process to *obtain understanding*, not something you do once you already understand.
- G. **It's even harder to trick others.** If an explanation you're providing doesn't make sense, they'll often tell you or you can pick up cues like blank stares. As a test, ask them to repeat what you taught them in their own words. If they can't do this, your explanation is too complex — simplify it and use plain language.
- H. **You build confidence.** When you truly understand something, it clicks. You can explain it forward and backwards, pointing out exceptions and spotting logical inconsistencies. When this happens, it builds confidence and pushes

you to tackle even more challenging subjects knowing you have a solid framework for learning.

X. Reflect, Refine, and Simplify.

- A. Only when you can explain the subject in simple terms do you understand it.**
- B. Simple is beautiful.**
- C. Review your notes to make sure you didn't mistakenly borrow any jargon or gloss over anything complicated.**
- D. Read it out loud as if to a child. If the explanation isn't simple enough or sounds confusing, that's a good indication that you need to reflect and refine.**
- E. Go back to the source material, reviewing the parts you don't quite understand yet.**
- F. Repeat until you have a simple explanation.**

XI. Return to the source material if you get stuck. Go back to whatever you're learning from – a book, lecture notes, Journal, Newspaper, podcast or any other resource and source – and fill the gaps in your knowledge.

- A. Step 1- Use The Chosen Rules of Reading Method For Analysis, Syntopicon, Research, Investigative Journalism or Mixed Method and Follow Each Steps Of The Method Until Finish All Steps, While Re-listen Lectures, Read Books or Lecture Notes 1-100 Times For Each Step.**
- B. Step 2- Following Rules of Reading Methods:**
- C. VERY VERY FAST Reading- Skimming. Pages 47-51.**
- D. VERY FAST READING- Entertainment.**
 - I. Method 1-Speed Reading. FAST Reading. Pages 59-64.**
- E. FAST READING: Methods for Basic Knowledge For Deep Work or Bible Study.**
 - I. Method 1-Survey, Question, Read, Recite, Record, Reflect (SQR4). Pages 66-67.**

 - IX. Method 9-Chapter Analysis Method. Pages 206-215.
 - X. Method 10-Paragraph Study. Pages 216-229.
 - XI. Method 11-Verse by Verse Analysis Method. Pages 230-234.
 - XII. Method 12-Book Synthesis Method. Pages 235-238.
 - XIII. Method 13-Theological Study Method of Bible Study. Pages 239-245.
 - XIV. Method 14-Studying Bible Prophecy. Pages 246-259.
 - XV. Method 15-Typological Study Method. Pages 260-262.
 - XVI. Method 16- John MacArthur Way Bible Study. Pages 263-268.
 - XVII. Method 17-Inductive Bible Study Method. Pages 269-296.
 - XVIII. Method 18-BIBLICAL HERMENEUTICS. Pages 297-302.
 - XIX. Method 19-Theological Group of Principles. Pages 303-306.
 - XX. Method 20- How To Read A Book Pages 307.

G. VERY VERY SLOW READING- COMPLEX TEXT. Deep Work, Shallow Work, Bible Study, Analysis of Text, Research, Investigative Journalism, Investigation and Syntopicon, Mixed Method.

- I. Method 21- How To Read A Book By Mortimer Adler Various edition Pages 341.**
- II. Method 22-How To Read A Book For Various Books. Pages 342-600.**
- III. Method 23- Syntopicon Pages 601-642.**
- IV. Method 24-The Craft of Research. Pages 644-882.**
- V. Method 25-Research Books can Be Used. Pages 883-897.**
- VI. Method 26-Investigative Journalism. Pages 898-923.**
- VII. Method 27-Mixed Methods of Rules of Reading. Pages 924-942.**

- H. Learning should be iterative. More often than not, learning something challenging takes several attempts. With the Feynman Technique, returning to the source material is an explicit part of the learning process. When gaps in our knowledge arise and our explanations aren't quite right, revisiting our primary and secondary sources can help solidify what we're learning.
- I. Getting it right will likely take several iterations. That's a good thing; the more you refine your explanations, the more your understanding will deepen. Learning becomes an iterative process. Rather than viewing learning as one-and-done, this step gives you permission to continuously refresh your knowledge.
- J. You're actively engaged. Using sources to polish our own explanations and models is an active process. When we learn passively, committing details to memory is more challenging. When we're actively part of creating our own summaries and reasoning, drawing intentionally from original information to fill our blind spots, we can more readily commit knowledge to our long-term memory.
- K. You expand your knowledge base. Paradoxically, the more we learn, the more *our capacity* to learn increases. Looking through a chapter of a textbook might feel like a different language the first time around. The second time it becomes more clear. The third time, with a strong base already, we pick up nuances we couldn't have possibly seen before.

VIII. Simplify your explanations and create analogies. Streamline your notes and explanation, further clarifying the topic until it seems obvious. Additionally, think of analogies that feel intuitive.

- A. Every field of study has its own specialised terms. While it may be important to know them, it's also important to not confuse knowing jargon with knowing concepts. The Feynman Technique involves simplifying our initial explanations and refining our understanding through simple analogies..Why this step works:
- B. Simplicity is a proxy for understanding. It's easy enough to commit terms to memory, and repeat them back when prompted. But memorisation is not understanding. When we can't rely on big words that make us sound smart, we have to distill what we truly know to the most basic form. This is where true understanding takes place.
- C. Analogies are easier to recall and explain. When you understand a challenging concept, analogies allow you to create a short-hand for recalling it quickly and explaining it to others clearly. Learning material often provides ready-made analogies for us. For example, we all probably have "the mitochondria are the powerhouse of the cell" burned into our collective memories. However, pushing ourselves to create our own analogies is even more powerful than regurgitating a borrowed one that we may not actually understand.

IX. Organize and Review

- A. To test your understanding in the real world, run it by someone else. How effective was your explanation? What questions did they ask? What parts did they get confused about?
- B. When you're happy with your understanding, take the page you created with a simple explanation and put it into a binder. Following this technique for everything you learn gives you a binder full of learning that you can review a couple of times a year.

*PART 23: Sport and Jiu-jitsu,
Judo Or Wrestling*

Step 162-What Trainings Do I Do On Daily Basis Schedule.

Decide The Training I Will Do It Today

A. Monday:

- I. Gym Jiujitsu.**
- II. Home Wrestling, Jiujitsu, Judo And Luta Livre.**
- III. Home Boxing.**
- IV. Home Muay Thai and Lethwei.**
- V. Home Sambo and MMA.**
- VI. Breath.**
- VII. Conditioning.**
- VIII. De-escalation.**
- IX. Situational Awareness.**

B. Tuesday:

- I. Home Wrestling, Jiujitsu, Judo And Luta Livre**
- II. Home Boxing.**
- III. Home Sambo and MMA.**
- IV. Home Muay Thai and Lethwei.**
- V. Breath.**
- VI. Strength.**

C. Wednesday:

- I. Gym JiuJitsu.**
- II. Home Wrestling, Judo, JiuJitsu And Luta Livre**
- III. Home Sambo and MMA.**
- IV. Home Boxing.**
- V. Home Muay Thai and Lethwei.**
- VI. Breath.**
- VII. Conditioning.**
- VIII. De-escalation.**
- IX. Situational Awareness.**

D. Thursday:

- I. Home Wrestling, JiuJitsu, Judo And Luta Livre**
- II. Home Sambo and MMA**
- III. Home Boxing.**
- IV. Home Muay Thai and Lethwei.**
- V. Stretch and Flexibility.**
- VI. Strength.**
- VII. Conditioning.**

E. Friday:

- I. Gym JiuJitsu.**
- II. Home Wrestling, JiuJitsu, Judo and Luta Livre.**
- III. Home Boxing.**
- IV. Home Sambo and MMA.**
- V. Home Muay Thai and Lethwei.**
- VI. Breath.**
- VII. Conditioning.**
- VIII. Stretch and Flexibility.**

F. Saturday:

- I. Home Wrestling, JiuJitsu, Judo And Luta Livre.**
- II. Home Boxing.**
- III. Home Sambo and MMA.**
- IV. Home Muay Thai and Lethwei.**
- V. Breath.**
- VI. Conditioning.**
- VII. Strength.**
- VIII. De-escalation.**
- IX. Situational Awareness.**

G. Sunday:

- I. Gym JiuJitsu**
- II. Home Wrestling, JiuJitsu, Judo And Luta Livre.**
- III. Home Boxing.**
- IV. Home Sambo and MMA.**
- V. Home Muay Thai and Lethwei.**
- VI. Breath.**
- VII. Conditioning.**
- VIII. Strength.**
- IX. Mental Tough.**
- X. De-escalation.**
- XI. Situational Awareness.**

Step 163-What Specific Training Do I Want To Practice Today

Step 1- Out of the Weekly And Daily Goals and Tasks, Decide One Technique, Practices and Exercise I will Drills Today For JiuJitsu, Judo or Wrestling. Check BJJ Template For The Different Practices in Excel.

- 1. Current Focus on Fundamental Skills At Home.**
- 2. Current Focus on 80/20 Principles of Attack and Defence of BJJ at Home.**
- 3. Sparring Focus on Defence.**
- 4. Sparring Focus on Attack.**
- 5. What To Do When Opponent Does, is or has.**
- 6. Instructional Video Of BJJ To Train.**
- 7. Video Link To The Technique and Good Resources.**
- 8. Mistakes and Solutions To Those Mistakes.**
- 9. Current Focus on What Practices at the BJJ Gym.**
- 10. Current Focus on Principles of Attack and Defence OF BJJ At Home.**

Step 2-Apply Step By step The technique as it was written in BJJ Template. Drill The Technique and Exercises At Home 1-1000 Times, Until I can do It Perfectly without any Problems.

Step 3- Prior The Gym, Prepare, My BJJ Game Plan For Rolling From BJJ Template The Following:

- 1. Current Focus on 80/20 Principles of Attack and Defence of BJJ at Home.**
- 2. Sparring Focus on Defence.**
- 3. Sparring Focus on Attack.**
- 4. Mistakes and Solutions To Those Mistakes.**

Step 4-Always Think About Every Steps in my attack or defence and see the following:

- **Use SWOT analysis of My Attack and Defence?**
- **USE SWOT Analysis of Opponent Attack and Defence?**
- **USE 80/20 Principle for My Attack, Defence, Sweep, Submission, Movement and Go To Move?**
- **USE 80/20 Principle for Opponent Attack, Defence, Sweep, Submission, Movement and Go To Move?**
- **What makes you uncomfortable in any area and work on the weaknesses of mine.**
- **In jiujitsu I have to prepare in things that makes me uncomfortable. Look for the techniques based on 80/20 principle. Look for the techniques that are simple but have the highest success rate.**
- **What mistakes I did In my attack and defence?**
- **What mistakes My opponent did in attack and defence?**
- **How Can I explore the mistakes and weaknesses of my opponent the attack and defence?**
- **How Can opponent explore mistakes and weaknesses of my attack and defence?**
- **Use 5W and 1 H**

Step 5-Use The Following Technique to Study, Watch and Predict Opponent Defence, Offence, Submission, Counterattack and Counter Defence:

- 1. Study and Watch Videos of the Person who I rolling, Sparing, and see the movements and the steps they are taking in order to take one position or the other. Use 80/20 Principle.**
 - I. See the opponent favourite attack Tactics:**
 - **USE SWOT analysis**
 - **Use 5W and 1 H.**

- Use 80/20 Principle
- Check The steps they are taking?
- What angles do they take?
- What are weaknesses of their in the attack?
- How can I explore their weakness in my defence?

II. See the opponent favourite defence tactics.

- Use SWOT Analysis
- Use 5W and 1 H.
- Use 80/20 Principle
- Check The steps they are taking?
- What angles do they take?
- What are weaknesses of their defence?
- How can I explore their weakness in my Defence?

2. Watch Live rolling of the person who I rolling, Sparring, and see the movements and the steps they are taking in order to take one position or the other. USE 80/20 Principle.

I. See the opponent favorite attack Tactics:

- Use SWOT Analysis
- Use 5W and 1 H.
- Use 80/20 Principle.
- Check The steps they are taking?
- What angles do they take?
- What are the Strengths and Weakness In Their Attack
- How can I explore their weakness in my defence?
- What Opportunities and Threats In their attack
- What opportunities and Threats I have in their attack?

II. See the opponent favourite defence tactics. Use 80/20 Principle.

- **USE SWOT ANALYSIS.**
- **Use 5W and 1 H.**
- **Use 80/20 Principle.**
- **Check The steps they are taking?**
- **What angles do they take?**
- **What are weaknesses of their defence?**
- **How can I explore their weakness in my Defence?**
- **What are the Strengths and Weakness In Their Defence?**
- **How can I explore their weakness in my Attack?**
- **What Opportunities and Threats In their DEFENCE?**
- **What opportunities and Threats I have in their DEFENCE?**

3. Use 80/20 Principle, Recognise Patterns- Pay attention the following:

- I. Where are the hands?**
- II. Where are the feet?**
- III. How the weight is distributed?**
- IV. Where the back?**
- V. Where is the whole body moves toward?**
- VI. Use 5W and 1 H**

4. Use 80/20 Principle In Prediction.

Step 6- Try to predict what opponent Step Would Be, if I take this or that route in the attack, defence, Submission, Counter Attack and Counter Submission. Based on The Step 5. Use 80/20 Principle AND SWOT.

Step 7- Try to predict opponent move in attacking, defence, Submission, Counter Attack, and Counter Defence and how can I counter? This is Based on the Step 5. Use 80/20 Principle AND SWOT.

Step 8- Try to predict the opponent defence, Submission and attack plan, when Roll. This is based on the Step 5. Use 80/20 Principle AND SWOT.

Step 9- Let The World Do The Work For You.

- 1. The world never tells you that you're wrong; it only gives you outcomes.**
- 2. Don't force. Don't resist. Have a beginner's mind. Let the world teach you.**
- 3. Reality will do a lot of the work for us if we simply align with it. Most of the time we're simply adding friction because we want the world to work in the way we think it should.**
- 4. If you don't see the world the way it is, you'll think it works in a way that it doesn't and make terrible mistakes. The key to getting what you want out of life is to identify how the world works and align yourself accordingly. This is hard because we think the world should work the way we see it. The word "should" is important. Because we think the world should work in a way that it doesn't, our approach is suboptimal. What the pupil must learn, if he learns anything at all, is that the world will do most of the work for you, provided you cooperate with it by identifying how it really works and aligning with those realities. If we do not let the world teach us, it teaches us a lesson. Joseph Tussman**
- 5. When an outcome is not what you want it to be, things get tough. You can ignore the result and continue to think that you're right. This protects your ego. It also carries the risk of your continuing to believe something that isn't true. Alternatively, you can calibrate your believability on the subject at hand by lowering the odds that you're right. For example, maybe you gave yourself an 85 out of 100 for the ability to hold a firm opinion on this subject, and now you lower your score to 75. If the world**

continues to provide undesirable outcomes, eventually you get the hint and change your beliefs. Finally, you can give up your opinions and just respond to the world as it is. This option is the hardest.

6. You do not create the way the world works, you can only align yourself with it. It takes a lot of work to align ourselves with reality. When we don't get the outcome we're seeking, the last place we look is inside ourselves. Instead, we blame others or circumstances. If you want to align yourself with reality, you have to work at it and care about it. There are two keys to aligning yourself with how the world really works: accepting feedback and stopping bargaining.
7. As Per Kobe Bryant statement: Trivial things should not be taken your attention. The attentions should be focused on things that is very important. Anything outside of the most important things in life, you should not have time for. You Should love the challenge in life, and always be curious, if you can be at the top , as these greats in that area. Always focus on one thing and not multiple things, this gives an edge and advantage over other people, who focusing on multiple things in life. The World Becomes a library to you, to be better at your craft.: Everything you see whether TV show I saw, Books, Journals, I read, whether discussion, debate I listen, people I talk to. Everything was done to try to learn to become better at the craft your focusing. When you have this point of you, then the world becomes your library to help you to become better at the craft.
8. Always look at the reality of the situation, and do not let the emotion cloud the situation and the execution. Always be in the present and the moment.
9. If you understand the world as it really is, not as you'd wish it to be, you will begin to make better decisions almost immediately.

Once you start making better decisions the results compound. Better initial decisions free up your time, reduce your stress, allowing you to spend more time with your family and leave your competition in the dust.

10. How can we best understand the world as it is? Acquiring knowledge can be a very daunting task. If you think of the mind as a toolbox, we're only as good as the tools at our disposal. A carpenter doesn't show up to work with an empty toolbox. Not only do they want as many tools in their toolbox as possible, but they want to know how to use them. Having more tools and the knowledge of how to use them means they can tackle more problems. Try as we might, we cannot build a house with only a hammer. If you're a knowledge worker, you're a carpenter. But your tools aren't bought at a store and they don't come in a red box that you carry around. Mental tools are the big ideas from multiple disciplines, and we store them in our mind. And if we have a lot of tools and the knowledge required to wield them properly, we can start to synthesize how the world works and make better decisions when confronted with problems.

11. This is how we understand and deal with reality. The tools you put into your toolbox are Mental Models. Mental models are a framework for understanding how the world really works. They help you grasp new ideas quickly, identify patterns before anyone else and shift your perspective with ease. Mental Models allow us to make better decisions, scramble out of bad situations, and think critically. If you want to understand reality you must look at a problem in multiple dimensions — how could it be otherwise? Getting to this level of understanding requires having a lot of tools and knowing how to use them. You knew there was a hitch right? We need to change our fast-food diet of information consumption and adopt the healthier diet

of knowledge that changes slowly over time. While changing diets isn't easy, it can be incredibly rewarding: more time, less stress, and being better at your job. The costs, however, are short term pain for long-term gain. You must change how you think.

Step 10- In the Gym Practice:

- 1. Warm Up**
- 2. Listen What Are Instruction in Practice.**
- 3. Use Normal, Diaphragmatic or Gracie Breathing.**
- 4. Practice The Drill and Think, How Can I execute this drill perfectly.**
- 5. Be Proactive.**
- 6. Take One Task At the Time.**
- 7. Develop Mental Toughness and Have Jordan and Kobe Mindset In JiuJitsu.**
- 8. Ask Questions.**
- 9. Respect The Instructor, Mat and Opponent.**
- 10. Practice And Fail, Practice and Fail, Practice until Success.**

Step 11- In the Gym Rolling or Competition.

- 1. Before The Roll Think The Defence, Attack, Submission or Sweep From BJJ Template I WILL Apply, and How Will I apply.**
- 2. Think While Rolling the Following:**
 - I. Think, How Can I execute The Game Plan From Start to the End by Being In any Position at the time.**
 - II. What Is the next Step Do I need To take, in order to fully execute the BJJ Template Game Plan.**
 - III. What Do I need to Do To Prevent Me to be in the position, where the opponent wants me to be.**
 - IV. Think also while rolling**
 - USE AND APPLY SWOT Analysis for Myself and Opponent**
 - USE and Apply 80/20 Principle For Myself and Analysing Opponent While Rolling.**
 - What mistakes I did In my attack and defence?**
 - What mistakes My opponent did in attack and defence?**
 - How Can I explore the mistakes and weaknesses of my opponent the attack and defence?**
 - How Can opponent explore mistakes and weaknesses of my attack and defence?**
 - Use 5W and 1H.**

Step 12- After The Roll, Analyse and Evaluate:

- 1. Success: Find what I have done well and worked**
 - Figured out how and why did they work well.**
 - How Can I make them work again.**
- 2. Failure: Find things I failed. How and why it did not Worked well?.**
- 3. Improvement: Find the things I could do better.**
- 4. Use 80/20 Principle.**

Step 13-After The Gym:

- 1. Show Respect By Bow.**
- 2. Thanking.**

Step 14-Progression of BJJ:

- 1. Without basics and foundations and fundamentals, you cannot progress.**
- 2. Repetition:**
 - I. Practice, Practice, Practice every day.**
 - II. Repeat 1000 times.**
 - III. Drill the moves 1000 times until I can do automatically.**
- 3. Use and Apply 80/20 Principle At all Time.**
- 4. USE SWOT ANALYSIS For Myself and Opponent.**
- 5. What makes you uncomfortable in any area and work on the weaknesses of mine.**
- 6. In jiu-jitsu I have to prepare in things that makes me uncomfortable. Look for the techniques based on 80/20 principle. Look for the techniques that are simple but have the highest success rate.**
- 7. A Cleaner: Means never being satisfied. It means creating new goals every time you reach your personal best. If you're good, it means you don't stop until you're great. If you're great, it means you fight until you're unstoppable.**
- 8. Steps to winning has infinite steps and constantly changing. Do not look for steps in success and winning. Work Hard, and try push to my limits.**
- 9. Perfect Your craft by doing over and over again.**
- 10. Fail over, and over again, as this leads to success.**
- 11. Never fear about the skills, if you put work. Work ethic eliminates fear. If you put work you know what you are capable of doing, what you are not**

- 12. Master your weakness, so they become strengths.**
- 13. Every day, challenge yourself to be uncomfortable.**
- 14. Every day, push yourself past your own mind-created limits and soon your old limits become your new normal.**
- 15. That's how you grow. By pushing your boundaries and expanding them.**
- 16. Relentless-Relentless is Attack, Attack the problem or the task and never give an inch to anybody and always go after, and if there is a challenge with this, be excited and see how you stack up and measure against this problem, if I am good enough. If I am not good enough I will prepare next time, I will be good enough.**
- 17. Stop looking for the shortcut. Do the work and Grind Constantly.**
- 18. Sorry, there's no off-season when you're serious about being a winner."**
- 19. Just show up, work hard, and listen. That's your part of the deal. Do the work.**
- 20. Take one challenge at the time, Once overcome the challenge, then move to another challenge and hardship.**
- 21. Be Resilience-Strength of character and toughness in any area of Life.**
- 22. Use 5W and 1 H.**

Step 164- Letting The World Do The Work For You

Letting The World Do The Work For You

1. Listen and Apply book
 - I. This Explains Everything_ Deep, Beautiful, and Elegant Theories of How the World Works
2. **The world never tells you that you're wrong; it only gives you outcomes.**
3. **Don't force. Don't resist. Have a beginner's mind. Let the world teach you.**
4. **Reality will do a lot of the work for us if we simply align with it. Most of the time we're simply adding friction because we want the world to work in the way we think it should.**
5. **If you don't see the world the way it is, you'll think it works in a way that it doesn't and make terrible mistakes. The key to getting what you want out of life is to identify how the world works and align yourself accordingly. This is hard because we think the world should work the way we see it. The word "should" is important. Because we think the world should work in a way that it doesn't, our approach is suboptimal. What the pupil must learn, if he learns anything at all, is that the world will do most of the work for you, provided you cooperate with it by identifying how it really works and aligning with those realities. If we do not let the world teach us, it teaches us a lesson. Joseph Tussman**
6. When an outcome is not what you want it to be, things get tough. You can ignore the result and continue to think that you're right. This protects your ego. It also carries the risk of your continuing to believe something that isn't true. Alternatively, you can calibrate your believability on the subject at hand by lowering the odds that you're right. For example, maybe you gave yourself an 85 out of 100 for the ability to hold a firm opinion on this subject, and now you lower your score to 75. If the world continues to provide undesirable outcomes, eventually you get the hint and change your beliefs. Finally, you can give up your opinions and just respond to the world as it is. This option is the hardest.

7. You do not create the way the world works, you can only align yourself with it. It takes a lot of work to align ourselves with reality. When we don't get the outcome we're seeking, the last place we look is inside ourselves. Instead, we blame others or circumstances. If you want to align yourself with reality, you have to work at it and care about it. There are two keys to aligning yourself with how the world really works: accepting feedback and stopping bargaining.

- I. We let people, not results, guide our behavior. The world tries to tell us when we don't see it the way it is. The problem is we don't listen to the world. Instead, we let others tell us what's right and wrong, what works, and what doesn't. Common actions get common results. Most of our actions come from others. We want what they want. Even worse, we employ the same actions to get it. This isn't always wrong. If you're just starting, the quickest path to average is to copy. If you want better results than average, you're going to have to iterate. Doing something different means we might look like a fool, and we do not want to look like a fool. Iterating means trying something new, it means you might fail. Show me a person who's afraid to look bad, and I'll show you a person you can beat every time. If we do what everyone else is doing, we're going to get the same results that everyone else is getting. Different results demand different actions. If you can't really fail, you can't really succeed. Let results, not popularity, determine your actions. If you're doing something that doesn't get you the results you want, try something new. If you're doing something that seems to work, keep doing it. Consistently repeat successful actions.
- II. Bargaining with the world doesn't work. A lot of otherwise smart people know what they're doing isn't getting the results they want, but because they think the world *should* work in a way that it doesn't, they keep repeating them hoping for different results. If you are this person, see it for what it is, and change your actions. The feedback from the world is often painful. Often, it is this very pain that causes us to no longer delude ourselves with how the world should work and accept how it does work. If you can learn to accept the world for how it is, before suffering, you'll go faster and further. Outcome over ego. If you think you know how the world works but you're doing something that gets suboptimal results because it *should* work a different way, you don't really know how the world works. Rational people take feedback from the world. If you want to know how someone sees the world, look at their actions. In the end, it's all your fault. You are accountable for your outcomes. When you take responsibility for your

outcomes, you naturally accept feedback from reality. When you get feedback from reality, you adjust your behavior.

- III. As Per Kobe Bryant statement: Trivial things should not be taken your attention. The attentions should be focused on things that is very important. Anything outside of the most important things in life, you should not have time for. You Should love the challenge in life, and always be curious, if you can be at the top , as these greats in that area. Always focus on one thing and not multiple things, this gives an edge and advantage over other people, who focusing on multiple things in life. The World Becomes a library to you, to be better at your craft.: Everything you see whether TV show I saw, Books, Journals, I read, whether discussion, debate I listen, people I talk to. Everything was done to try to learn to become better at the craft your focusing. When you have this point of you, then the world becomes your library to help you to become better at the craft.
- IV. Have the best work ethic on daily basis. This is everyday process, and try to figure it out, the strengths and weaknesses of my position and opposing person position.
- V. Always look at the reality of the situation, and do not let the emotion cloud the situation and the execution. Always be in the present and the moment.
- VI. If you understand the world as it really is, not as you'd wish it to be, you will begin to make better decisions almost immediately. Once you start making better decisions the results compound. Better initial decisions free up your time, reduce your stress, allowing you to spend more time with your family and leave your competition in the dust.
- VII. How can we best understand the world as it is? Acquiring knowledge can be a very daunting task. If you think of the mind as a toolbox, we're only as good as the tools at our disposal. A carpenter doesn't show up to work with an empty toolbox. Not only do they want as many tools in their toolbox as possible, but they want to know how to use them. Having more tools and the knowledge of how to use them means they can tackle more problems. Try as we might, we cannot build a house with only a hammer. If you're a knowledge worker, you're a carpenter. But your tools aren't bought at a store and they don't come in a red box that you carry around. Mental tools are the big ideas from multiple disciplines, and we store them in our mind. And if we have a lot of tools and the knowledge required to wield them properly, we can start to synthesize how the world works and make better decisions when confronted with problems.

VIII. This is how we understand and deal with reality. The tools you put into your toolbox are Mental Models. Mental models are a framework for understanding how the world really works. They help you grasp new ideas quickly, identify patterns before anyone else and shift your perspective with ease. Mental Models allow us to make better decisions, scramble out of bad situations, and think critically. If you want to understand reality you must look at a problem in multiple dimensions — how could it be otherwise? Getting to this level of understanding requires having a lot of tools and knowing how to use them. You knew there was a hitch right? We need to change our fast-food diet of information consumption and adopt the healthier diet of knowledge that changes slowly over time. While changing diets isn't easy, it can be incredibly rewarding: more time, less stress, and being better at your job. The costs, however, are short term pain for long-term gain. You must change how you think.

IX. 2nd Order Thinking. One example of a model we can immediately conceptualize and use to improve our ability to make better decisions is something we can borrow from ecology called second-order thinking. The simple way to conceptualize this is to ask yourself "If I do X, what will happen *after* that?". I sum this up using the ecologist Garrett Hardin's simple question: "And then what?" A lot of people forget about higher order effects — second and third-order effects or higher. I've been in a lot of meetings where decisions are made and very few people think to the second level, let alone the third. Rather, what typically happens is called first conclusion bias. The brain shuts down and stops thinking at the first idea that comes to mind that seems to address the problem as you understand it. We don't often realize that our first thoughts are usually not even our own thoughts. They usually belong to someone else. We understand the sound-byte but we haven't done the hard work of real thinking. After we reach the first conclusion, our minds often shut down. We don't seek evidence that would contradict our conclusion. We don't ask ourselves what the likely result of this solution would be — we don't ask ourselves "And then what?" We don't ask what other solutions might be even *more* optimal. For example, consider a hypothetical organization that decides to change their incentive systems. They come up with a costly new system that requires substantial changes to the current system. Only they don't consider (or even understand) the problems that the *new* system is likely to create. It's possible they've created more problems than they've solved — only now there are *different* problems they must put their head down to solve.

Optically, they “reorganize their incentive programs,” but practically, they’ve simply expended energy to stay in place. Another, perhaps more complicated, example is when a salesman comes into a company and offers you a software program he claims will lower your operating costs and increase your profits. He’s got all these beautiful charts on how much more competitive you’ll be and how it will improve everything. This is exactly what you need because your compensation is based on increasing profits. You’re sold. Then second-order thinking kicks in and you dare to ask how much of those cost savings are going to go to you and how much will eventually end up benefits enjoyed by customers? To a large extent, that depends on the business you’re in. However, you can be damn sure the salesman is now knocking on your competitor’s door and telling them you just bought their product and if they want to remain competitive they better purchase it too. Eventually, you all have the new software and no one is truly better off. Thus, in the manner of a crowd of people standing on their tip-toes at a parade, all competitors spend the money but none of them win: The salesman wins and the customer wins. We know, thanks to people like Garrett Hardin, Howard Marks, Charlie Munger, Peter Kaufman, and disciplines like ecology, that there are second and third-order effects. This is how the world really works. It just isn’t always a comfortable reality. Understanding how the world works isn’t easy and it shouldn’t be. It’s hard work. If it were easy, everyone would do it. And it’s not for everyone. Sometimes, if your goal is to maximize utility, you should focus on getting very, very good in a narrow area and becoming an expert, accepting that you will make many mistakes outside of that domain. But for most, it’s extremely helpful to understand the forces at play outside of their narrow area of expertise. Because when you think about it, how could reality be anything other than a synthesis of multiple factors? How could it possibly be otherwise?

- X. When our mental models line up with reality, they help us avoid problems. However, they also cause problems when they don’t line up with reality as we think something that isn’t true.
- XI. We must be open to other perspectives if we truly want to understand the results of our actions. Despite feeling that we’ve got all the information, if we’re on the ship, the fish in the ocean has more he can share. The second flaw is ego. Many of us tend to have too much invested in our opinions of ourselves to see the world’s feedback—the feedback we need to update our beliefs about reality. This creates a profound ignorance that keeps us banging our head against the wall

over and over again. Our inability to learn from the world because of our ego happens for many reasons, but two are worth mentioning here. First, we're so afraid about what others will say about us that we fail to put our ideas out there and subject them to criticism. This way we can always be right. Second, if we do put our ideas out there and they are criticized, our ego steps in to protect us. We become invested in defending instead of upgrading our ideas. The third flaw is distance. The further we are from the results of our decisions, the easier it is to keep our current views rather than update them. When you put your hand on a hot stove, you quickly learn the natural consequence. You pay the price for your mistakes. Since you are a pain avoiding creature, you update your view. Before you touch another stove, you check to see if it's hot. But you don't just learn a micro lesson that applies in one situation. Instead, you draw a general abstraction, one that tells you to check before touching anything that could potentially be hot. Organizations over a certain size often remove us from the direct consequences of our decisions. When we make decisions that other people carry out, we are one or more levels removed and may not immediately be able to update our understanding

Step 165- Reflection, Review and Improvement

Record Reflection, Review and Improvement

A. Record the Reflection and Review.

B. Analyse: If I win or Lose, I should be excited. If I win or loss, the process should be exactly the same. You have to go back and look:

1. JiuJitsu, Wrestling, Judo.

- **Was There an improvement by 1%, where was the improvement.**
- **Success: Find what I have done well and worked well.**
 - **Figured out how and why did they work well.**
 - **How Can I make them work work again.**
- **Use 5W and 1 H**

- **Failure: Was there a declined by 1%, where was the decline?**
- **Find things I failed: Figured out how and why they did not work.**
- **Use 5W and 1 H**

Improvement

- **Find the things I could do better.**
- **What First to Improve in Steps of Performance.**
- **What to Change for better Performance.**
- **Decide and Prioritise 1-3 Challenges and Problems to improve**
- **Steps I will Take To Improve.**
- **Look at the improvement over the long period of time, and decide the steps I will take to improve. Look at the improvement as marathon, where you step by step improving.**
- **Take One Step at the time to move forward.**
- **Use 80/20 Principle.**
- **Use 5W and 1H.**

- **No Shortcut. Mastery does not tolerate shortcuts. Shortcuts exist to get better results with the same amount of pain/effort. It can neither scale nor work in the long term. The only way to go beyond your limitations is to do more, and better**

Analyse

- **Use 80/20 Principle.**
- **Use 5W and 1H.**
- **Find, Study and Analyse my weakness and Strengths. Work hard on my weaknesses. Perfect my strengths and work hard on my strengths.**
- **Study and Analyse the strength and weakness of the opponent or competitors and work with your weakness to their strengths.**
- **Analyse My Mistakes in Rolling.**
- **Analyse Opponent Mistakes in Rolling.**
- **Find and Analyse The Opportunity and Threat.**

*Part 24: Sport and Fighting Sport,
Conditioning, Stretching and
Flexibility, Strength, Breathing,
Mental Tough And Develop
Mindset.*

Step 166-Books On Muscle Training

Books On Sport

1. Home workout circuit training 6 week exercise band workout & bodyweight training.
2. Men's Health Home Workout Bible.
3. Men's Health Natural Bodybuilding Bible_ A Complete 24-Week Program For Sculpting Muscles That Show.
4. Men's Health Your Body is Your Barbell_ No Gym. Just Gravity. Build a Leaner, Stronger, More Muscular You in 28 Days!.
5. Predictive analytics for dummies.
6. The Men's Health and Women's Health Big Book of Sex_ Your Authoritative, Red-Hot Guide to the Sex of Your Dreams.
7. The Men's Health Big Book of Exercises_ Four Weeks to a Leaner, Stronger, More Muscular YOU!
8. The Men's Health Big Book_ Getting Abs_ Get a Flat, Ripped Stomach and Your Strongest Body Ever--in Four Weeks.
9. The Women's Health Big Book of Exercises_ Four Weeks to a Leaner, Sexier, Healthier YOU!.
10. The Women's Health big book of yoga_ the essential guide to complete mind_body fitness.

Step 167-What Trainings Do I Do On Daily Basis Schedule.

Decide The Training I Will Do It Today

A. Monday:

- I. Gym JiuJitsu.**
- II. Home Wrestling, JiuJitsu, Judo And Luta Livre.**
- III. Home Boxing.**
- IV. Home Muay Thai and Lethwei.**
- V. Home Sambo and MMA.**
- VI. Breath.**
- VII. Conditioning.**
- VIII. Deescalation.**
- IX. Situational Awareness.**

B. Tuesday:

- I. Home Wrestling, JiuJitsu, Judo And Luta Livre**
- II. Home Boxing.**
- III. Home Sambo and MMA.**
- IV. Home Muay Thai and Lethwei.**
- V. Breath.**
- VI. Strength.**

C. Wednesday:

- I. Gym JiuJitsu.**
- II. Home Wrestling, Judo, JiuJitsu And Luta Livre**
- III. Home Sambo and MMA.**
- IV. Home Boxing.**
- V. Home Muay Thai and Lethwei.**
- VI. Breath.**
- VII. Conditioning.**
- VIII. Deescalation.**
- IX. Situational Awareness.**

D. Thursday:

- I. Home Wrestling, JiuJitsu, Judo And Luta Livre**
- II. Home Sambo and MMA**
- III. Home Boxing.**
- IV. Home Muay Thai and Lethwei.**
- V. Stretch and Flexibility.**
- VI. Strength.**
- VII. Conditioning.**

E. Friday:

- I. Gym JiuJitsu.**
- II. Home Wrestling, JiuJitsu, Judo and Luta Livre.**
- III. Home Boxing.**
- IV. Home Sambo and MMA.**
- V. Home Muay Thai and Lethwei.**
- VI. Breath.**
- VII. Conditioning.**
- VIII. Stretch and Flexibility.**

F. Saturday:

- I. Home Wrestling, JiuJitsu, Judo And Luta Livre.**
- II. Home Boxing.**
- III. Home Sambo and MMA.**
- IV. Home Muay Thai and Lethwei.**
- V. Breath.**
- VI. Conditioning.**
- VII. Strength.**
- VIII. Deescalation.**
- IX. Situational Awareness.**

G. Sunday:

- I. Gym Jiujitsu**
- II. Home Wrestling, Jiujitsu, Judo And Luta Livre.**
- III. Home Boxing.**
- IV. Home Sambo and MMA.**
- V. Home Muay Thai and Lethwei.**
- VI. Breath.**
- VII. Conditioning.**
- VIII. Strength.**
- IX. Mental Tough.**
- X. Deescalation.**
- XI. Situational Awareness.**

Step 168-What Specific Training Do I Want To Practice Today

Step 1- Out of the Weekly And Daily Goals and Tasks, Decide 1-4 Techniques, Practices and Exercise I will Drills Today For Boxing, Sambo, MMA, Muay Thai, Lethwei, Conditioning, Stretching and Flexibility, Strength, Breathing, Mental Tough And Develop Mindset. Check BJJ Template For The Different Practices in Excel.:

1. Muay Thai and Lethwei

- A. Nutrition.**
- B. Warm up.**
- C. Clinch.**
- D. Low Kicks.**
- E. High Kicks.**
- F. Knees.**
- G. Elbows.**
- H. Hooks.**
- I. Uppercuts.**
- J. Defence.**
- K. Headbutt**
- L. Offence.**
- M. Leg workouts.**
- N. Drills.**

2. Boxing.

- A. Nutrition.**
- B. Warm Up.**
- C. Hooks.**
- D. Straights.**
- E. Uppercuts.**
- F. Jabs.**
- G. Leg Works.**
- H. Drills**

3. Conditioning.

- A. Nutrition.**
- B. Cycling.**
- C. Jogging or Run.**

4. Stretching and Flexibility.

- A. Nutrition**
- B. Head.**
- C. Shoulders.**
- D. Hands.**
- E. Hips.**
- F. Legs.**
- G. Feet.**

5. Strength.

- A. Listen and Watch Men's Health Big Book Exercise Pages 1-1100.**
- B. Nutrition.**
- C. Warm Up.**
- D. Hands.**
- E. Chest.**
- F. Back.**
- G. Shoulders.**
- H. Arms.**
- I. Quadriceps and Calves.**
- J. Glutes and Hamstring.**
- K. Core.**
- L. Total Body.**

6. Breathing.

- A. Nutrition.**
- B. Normal Breathing.**
 - Inhale through nose.
 - Exhale through mouth.
 - Do 5-10 minutes a day.
- C. Diaphragmatic Breathing.**
 - One Hand on Chest, Other on Stomach.
 - Inhale Slowly through Nose, and air push stomach upward against the hand, while chest remain still.
 - Exhale through Pursed lips, push stomach downward and chest remains still.
 - Do 5-10 Min times a day.

D. Gracie Breath.

- Lay or Sit on Flat Surface.
- One Hand on Chest, Other on Stomach.
- Inhale air through Nose Gradually increasing air in the body.
- Hand on the chest should be immobile, and the hand on the belly is moving upward.
- Back Should not be inflated
- Exhale through pursed lips do percussive- 5 beats saying (Shh, Shh, Shh, Shh, Shh).
- Hand on the belly goes downward.
- Do 5-10 Min times a day.

7. Mental Tough And Develop Mindset.

A. Mental Toughness.

- Be the best in each class, Drill, Roll and Competition.
- Do not let defeat, Negative thinking ruin self image.
- Give my best in each Drill, Roll and Competition.
- Never Give up.
- Let the EGO be in check in each Drill, Class, Roll and Competition.
- Be the hardest working person in each Class, Drill, Roll and Competition.
- Always Find Motivation to be better, this could be personal or something inside pushing to be better.
- Give 100% in Each Class, Training at home, Drill, Roll, Competition.
- When something goes wrong, get it over and move on.
- After each class, training at home, drill, roll and competition, think what Good did I do, and the failures.
- Be Proactive in my class, drill, home training, roll, and competition and respond positively, and focus and act on what I can control and influence, instead the things I cannot influence and control from outside.
- Take One task at the time to learn, and proficient the technique.
- Mentally tough people, never blame others, in what life throws at them, instead take full responsibility for what happens in their life.

- Get out of the comfort Zone to challenge myself, and by doing this build mental toughness.
- Be Relentless.
- Stop Make Excuses and Practice Practice Practice.
- Be aware of weakness of my BJJ and work hard on to overcome, and that this weakness become my strength.
- Fail to go forward fast.
- Evaluate my experiences and come up with a strategy to not fail again and execute new strategy.
- Hard work conquers all.
- Have a good work habits.
- Reevaluate my BJJ and reflect on daily, weekly, monthly and yearly basis.

B. Mindset

- Accept the failure, but never accept not trying.
- Train hard in class, at home, drill so that it would be easier in competition.
- Bleed more in training, at home, drills, so that you less bleed in the battle.
- Be Hardest Working Everywhere I go.
- Look For Challenge and overcome those Challenges.
- Look For Failures as Path for Success.
- Discipline myself wake up early and train and work hardest day in and day out.
- Word Hard like nobody will ever work.
- Constantly practice and upgrade myself.
- Earn successfully through determination consistent practice and put lots of effort.
- If I want to be best, there is no shortcuts, therefore work hardest.
- Do not afraid struggles, but embrace and work harder on daily basis.
- Stay in the moment and be in the present, and not somewhere else.
- Give my best all the time.
- Be intense I my training, drill, train at home, roll and competition.

Step 2-Apply Step By step The technique as it was written in BJJ Template. Drill The Technique and Exercises At Home 1-1000 Times, Until I can do It Perfectly without any Problems.

Step 3-Always Think About Every Steps in my attack or defence and see the following:

- **80/20 of My Attack and Defence?**
- **80/20 of Opponent Attack and Defence?**
- **USE SWOT Analysis for My Attack and Defence?**
- **Use SWOT ANALYSIS For Opponent Attack and Defence?**
- **What mistakes I did In my attack and defence?**
- **What mistakes My opponent did in attack and defence?**
- **How Can I explore the mistakes and weaknesses of my opponent the attack and defence?**
- **How Can opponent explore mistakes and weaknesses of my attack and defence?**

Step 4-Use The Following Technique to Study, Watch and Predict Opponent Defence, Offence, Submission, Counterattack and Counter Defence:

- 1. Study and Watch Videos of the Person who I rolling, Sparring, and see the movements and the steps they are taking in order to take one position or the other.**
 - I. See the opponent favourite attack Tactics:**
 - **Check The steps they are taking?**
 - **What angles do they take?**
 - **What are weaknesses of the attack?**
 - **How can I explore their weakness in my defence?**
 - II. See the opponent favourite defence tactics.**
 - **Check The steps they are taking?**

- What angles do they take?
- What are weaknesses of their defence?
- How can I explore their weakness in my Defence?

Step 5- Try to predict what opponent Step Would Be, if I take this or that route in the attack, defence, Submission, Counter Attack and Counter Submission. Based on The Step 5.

Step 6- Try to predict opponent move in attacking, defence, Submission, Counter Attack, and Counter Defence and how can I counter? This is Based on the Step 5.

Step 7- Try to predict the opponent defence, Submission and attack plan, when Roll. This is based on the Step 5.

Step 8- Let The World Do The Work For You.

1. The world never tells you that you're wrong; it only gives you outcomes.
2. Don't force. Don't resist. Have a beginner's mind. Let the world teach you.
3. Reality will do a lot of the work for us if we simply align with it. Most of the time we're simply adding friction because we want the world to work in the way we think it should.
4. If you don't see the world the way it is, you'll think it works in a way that it doesn't and make terrible mistakes. The key to getting what you want out of life is to identify how the world works and align yourself accordingly. This is hard because we think the world should work the way we see it. The word "should" is important. Because we think the world should work in a way that it doesn't, our approach is suboptimal. What the pupil must learn, if he learns anything at all, is that the world will do most of

the work for you, provided you cooperate with it by identifying how it really works and aligning with those realities. If we do not let the world teach us, it teaches us a lesson. Joseph Tussman

5. When an outcome is not what you want it to be, things get tough. You can ignore the result and continue to think that you're right. This protects your ego. It also carries the risk of your continuing to believe something that isn't true. Alternatively, you can calibrate your believability on the subject at hand by lowering the odds that you're right. For example, maybe you gave yourself an 85 out of 100 for the ability to hold a firm opinion on this subject, and now you lower your score to 75. If the world continues to provide undesirable outcomes, eventually you get the hint and change your beliefs. Finally, you can give up your opinions and just respond to the world as it is. This option is the hardest.
6. You do not create the way the world works, you can only align yourself with it. It takes a lot of work to align ourselves with reality. When we don't get the outcome we're seeking, the last place we look is inside ourselves. Instead, we blame others or circumstances. If you want to align yourself with reality, you have to work at it and care about it. There are two keys to aligning yourself with how the world really works: accepting feedback and stopping bargaining.
7. As Per Kobe Bryant statement: Trivial things should not be taken your attention. The attentions should be focused on things that is very important. Anything outside of the most important things in life, you should not have time for. You Should love the challenge in life, and always be curious, if you can be at the top , as these greats in that area. Always focus on one thing and not multiple things, this gives an edge and advantage over other people, who focusing on multiple things in life. The World

Becomes a library to you, to be better at your craft.: Everything you see whether TV show I saw, Books, Journals, I read, whether discussion, debate I listen, people I talk to. Everything was done to try to learn to become better at the craft your focusing. When you have this point of you, then the world becomes your library to help you to become better at the craft.

8. Always look at the reality of the situation, and do not let the emotion cloud the situation and the execution. Always be in the present and the moment.
9. If you understand the world as it really is, not as you'd wish it to be, you will begin to make better decisions almost immediately. Once you start making better decisions the results compound. Better initial decisions free up your time, reduce your stress, allowing you to spend more time with your family and leave your competition in the dust.
10. How can we best understand the world as it is? Acquiring knowledge can be a very daunting task. If you think of the mind as a toolbox, we're only as good as the tools at our disposal. A carpenter doesn't show up to work with an empty toolbox. Not only do they want as many tools in their toolbox as possible, but they want to know how to use them. Having more tools and the knowledge of how to use them means they can tackle more problems. Try as we might, we cannot build a house with only a hammer. If you're a knowledge worker, you're a carpenter. But your tools aren't bought at a store and they don't come in a red box that you carry around. Mental tools are the big ideas from multiple disciplines, and we store them in our mind. And if we have a lot of tools and the knowledge required to wield them properly, we can start to synthesize how the world works and make better decisions when confronted with problems.

11. This is how we understand and deal with reality. The tools you put into your toolbox are Mental Models. Mental models are a framework for understanding how the world really works. They help you grasp new ideas quickly, identify patterns before anyone else and shift your perspective with ease. Mental Models allow us to make better decisions, scramble out of bad situations, and think critically. If you want to understand reality you must look at a problem in multiple dimensions — how could it be otherwise? Getting to this level of understanding requires having a lot of tools and knowing how to use them. You knew there was a hitch right? We need to change our fast-food diet of information consumption and adopt the healthier diet of knowledge that changes slowly over time. While changing diets isn't easy, it can be incredibly rewarding: more time, less stress, and being better at your job. The costs, however, are short term pain for long-term gain. You must change how you think.

Step 9- After The Roll, Analyse and Evaluate:

1. **Success: Find what I have done well and worked**
 - Figured out how and why did they work well.
 - How Can I make them work again.
2. **Failure: Find things I failed. How and why it did not Worked well?.**
3. **Improvement: Find the things I could do better.No Shortcut. Mastery does not tolerate shortcuts. Shortcuts exist to get better results with the same amount of pain/effort. It can neither scale nor work in the long term. The only way to go beyond your limitations is to do more, and better**

Step 169- Letting The World Do The Work For You

Letting The World Do The Work For You

1. Listen and Apply book
 - I. This Explains Everything_ Deep, Beautiful, and Elegant Theories of How the World Works
2. **The world never tells you that you're wrong; it only gives you outcomes.**
3. **Don't force. Don't resist. Have a beginner's mind. Let the world teach you.**
4. **Reality will do a lot of the work for us if we simply align with it. Most of the time we're simply adding friction because we want the world to work in the way we think it should.**
5. **If you don't see the world the way it is, you'll think it works in a way that it doesn't and make terrible mistakes. The key to getting what you want out of life is to identify how the world works and align yourself accordingly. This is hard because we think the world should work the way we see it. The word "should" is important. Because we think the world should work in a way that it doesn't, our approach is suboptimal. What the pupil must learn, if he learns anything at all, is that the world will do most of the work for you, provided you cooperate with it by identifying how it really works and aligning with those realities. If we do not let the world teach us, it teaches us a lesson. Joseph Tussman**
6. When an outcome is not what you want it to be, things get tough. You can ignore the result and continue to think that you're right. This protects your ego. It also carries the risk of your continuing to believe something that isn't true. Alternatively, you can calibrate your believability on the subject at hand by lowering the odds that you're right. For example, maybe you gave yourself an 85 out of 100 for the ability to hold a firm opinion on this subject, and now you lower your score to 75. If the world continues to provide undesirable outcomes, eventually you get the hint and change your beliefs. Finally, you can give up your opinions and just respond to the world as it is. This option is the hardest.

7. You do not create the way the world works, you can only align yourself with it. It takes a lot of work to align ourselves with reality. When we don't get the outcome we're seeking, the last place we look is inside ourselves. Instead, we blame others or circumstances. If you want to align yourself with reality, you have to work at it and care about it. There are two keys to aligning yourself with how the world really works: accepting feedback and stopping bargaining.

- I. We let people, not results, guide our behavior. The world tries to tell us when we don't see it the way it is. The problem is we don't listen to the world. Instead, we let others tell us what's right and wrong, what works, and what doesn't. Common actions get common results. Most of our actions come from others. We want what they want. Even worse, we employ the same actions to get it. This isn't always wrong. If you're just starting, the quickest path to average is to copy. If you want better results than average, you're going to have to iterate. Doing something different means we might look like a fool, and we do not want to look like a fool. Iterating means trying something new, it means you might fail. Show me a person who's afraid to look bad, and I'll show you a person you can beat every time. If we do what everyone else is doing, we're going to get the same results that everyone else is getting. Different results demand different actions. If you can't really fail, you can't really succeed. Let results, not popularity, determine your actions. If you're doing something that doesn't get you the results you want, try something new. If you're doing something that seems to work, keep doing it. Consistently repeat successful actions.
- II. Bargaining with the world doesn't work. A lot of otherwise smart people know what they're doing isn't getting the results they want, but because they think the world *should* work in a way that it doesn't, they keep repeating them hoping for different results. If you are this person, see it for what it is, and change your actions. The feedback from the world is often painful. Often, it is this very pain that causes us to no longer delude ourselves with how the world should work and accept how it does work. If you can learn to accept the world for how it is, before suffering, you'll go faster and further. Outcome over ego. If you think you know how the world works but you're doing something that gets suboptimal results because it *should* work a different way, you don't really know how the world works. Rational people take feedback from the world. If you want to know how someone sees the world, look at their actions. In the end, it's all your fault. You are accountable for your outcomes. When you take responsibility for your

outcomes, you naturally accept feedback from reality. When you get feedback from reality, you adjust your behavior.

- III. As Per Kobe Bryant statement: Trivial things should not be taken your attention. The attentions should be focused on things that is very important. Anything outside of the most important things in life, you should not have time for. You Should love the challenge in life, and always be curious, if you can be at the top , as these greats in that area. Always focus on one thing and not multiple things, this gives an edge and advantage over other people, who focusing on multiple things in life. The World Becomes a library to you, to be better at your craft.: Everything you see whether TV show I saw, Books, Journals, I read, whether discussion, debate I listen, people I talk to. Everything was done to try to learn to become better at the craft your focusing. When you have this point of you, then the world becomes your library to help you to become better at the craft.
- IV. Have the best work ethic on daily basis. This is everyday process, and try to figure it out, the strengths and weaknesses of my position and opposing person position.
- V. Always look at the reality of the situation, and do not let the emotion cloud the situation and the execution. Always be in the present and the moment.
- VI. If you understand the world as it really is, not as you'd wish it to be, you will begin to make better decisions almost immediately. Once you start making better decisions the results compound. Better initial decisions free up your time, reduce your stress, allowing you to spend more time with your family and leave your competition in the dust.
- VII. How can we best understand the world as it is? Acquiring knowledge can be a very daunting task. If you think of the mind as a toolbox, we're only as good as the tools at our disposal. A carpenter doesn't show up to work with an empty toolbox. Not only do they want as many tools in their toolbox as possible, but they want to know how to use them. Having more tools and the knowledge of how to use them means they can tackle more problems. Try as we might, we cannot build a house with only a hammer. If you're a knowledge worker, you're a carpenter. But your tools aren't bought at a store and they don't come in a red box that you carry around. Mental tools are the big ideas from multiple disciplines, and we store them in our mind. And if we have a lot of tools and the knowledge required to wield them properly, we can start to synthesize how the world works and make better decisions when confronted with problems.

VIII. This is how we understand and deal with reality. The tools you put into your toolbox are Mental Models. Mental models are a framework for understanding how the world really works. They help you grasp new ideas quickly, identify patterns before anyone else and shift your perspective with ease. Mental Models allow us to make better decisions, scramble out of bad situations, and think critically. If you want to understand reality you must look at a problem in multiple dimensions — how could it be otherwise? Getting to this level of understanding requires having a lot of tools and knowing how to use them. You knew there was a hitch right? We need to change our fast-food diet of information consumption and adopt the healthier diet of knowledge that changes slowly over time. While changing diets isn't easy, it can be incredibly rewarding: more time, less stress, and being better at your job. The costs, however, are short term pain for long-term gain. You must change how you think.

IX. 2nd Order Thinking. One example of a model we can immediately conceptualize and use to improve our ability to make better decisions is something we can borrow from ecology called second-order thinking. The simple way to conceptualize this is to ask yourself "If I do X, what will happen *after* that?". I sum this up using the ecologist Garrett Hardin's simple question: "And then what?" A lot of people forget about higher order effects — second and third-order effects or higher. I've been in a lot of meetings where decisions are made and very few people think to the second level, let alone the third. Rather, what typically happens is called first conclusion bias. The brain shuts down and stops thinking at the first idea that comes to mind that seems to address the problem as you understand it. We don't often realize that our first thoughts are usually not even our own thoughts. They usually belong to someone else. We understand the sound-byte but we haven't done the hard work of real thinking. After we reach the first conclusion, our minds often shut down. We don't seek evidence that would contradict our conclusion. We don't ask ourselves what the likely result of this solution would be — we don't ask ourselves "And then what?" We don't ask what other solutions might be even *more* optimal. For example, consider a hypothetical organization that decides to change their incentive systems. They come up with a costly new system that requires substantial changes to the current system. Only they don't consider (or even understand) the problems that the *new* system is likely to create. It's possible they've created more problems than they've solved — only now there are *different* problems they must put their head down to solve.

Optically, they “reorganize their incentive programs,” but practically, they’ve simply expended energy to stay in place. Another, perhaps more complicated, example is when a salesman comes into a company and offers you a software program he claims will lower your operating costs and increase your profits. He’s got all these beautiful charts on how much more competitive you’ll be and how it will improve everything. This is exactly what you need because your compensation is based on increasing profits. You’re sold. Then second-order thinking kicks in and you dare to ask how much of those cost savings are going to go to you and how much will eventually end up benefits enjoyed by customers? To a large extent, that depends on the business you’re in. However, you can be damn sure the salesman is now knocking on your competitor’s door and telling them you just bought their product and if they want to remain competitive they better purchase it too. Eventually, you all have the new software and no one is truly better off. Thus, in the manner of a crowd of people standing on their tip-toes at a parade, all competitors spend the money but none of them win: The salesman wins and the customer wins. We know, thanks to people like Garrett Hardin, Howard Marks, Charlie Munger, Peter Kaufman, and disciplines like ecology, that there are second and third-order effects. This is how the world really works. It just isn’t always a comfortable reality. Understanding how the world works isn’t easy and it shouldn’t be. It’s hard work. If it were easy, everyone would do it. And it’s not for everyone. Sometimes, if your goal is to maximize utility, you should focus on getting very, very good in a narrow area and becoming an expert, accepting that you will make many mistakes outside of that domain. But for most, it’s extremely helpful to understand the forces at play outside of their narrow area of expertise. Because when you think about it, how could reality be anything other than a synthesis of multiple factors? How could it possibly be otherwise?

- X. When our mental models line up with reality, they help us avoid problems. However, they also cause problems when they don’t line up with reality as we think something that isn’t true.
- XI. We must be open to other perspectives if we truly want to understand the results of our actions. Despite feeling that we’ve got all the information, if we’re on the ship, the fish in the ocean has more he can share. The second flaw is ego. Many of us tend to have too much invested in our opinions of ourselves to see the world’s feedback—the feedback we need to update our beliefs about reality. This creates a profound ignorance that keeps us banging our head against the wall

over and over again. Our inability to learn from the world because of our ego happens for many reasons, but two are worth mentioning here. First, we're so afraid about what others will say about us that we fail to put our ideas out there and subject them to criticism. This way we can always be right. Second, if we do put our ideas out there and they are criticized, our ego steps in to protect us. We become invested in defending instead of upgrading our ideas. The third flaw is distance. The further we are from the results of our decisions, the easier it is to keep our current views rather than update them. When you put your hand on a hot stove, you quickly learn the natural consequence. You pay the price for your mistakes. Since you are a pain avoiding creature, you update your view. Before you touch another stove, you check to see if it's hot. But you don't just learn a micro lesson that applies in one situation. Instead, you draw a general abstraction, one that tells you to check before touching anything that could potentially be hot. Organizations over a certain size often remove us from the direct consequences of our decisions. When we make decisions that other people carry out, we are one or more levels removed and may not immediately be able to update our understanding

Step 170 - Reflection, Review and Improvement

Record Reflection, Review and Improvement

A. Record the Reflection and Review.

B. Analyse: If I win or Lose, I should be excited. If I win or loss, the process should be exactly the same. You have to go back and look:

1. Muay Thai, Lethwei Boxing, Strength, Conditioning, Breath, Stretching, Flexibility, Mental Tough and Mindset.

- **Was There an improvement by 1%, where was the improvement.**
- **Success: Find what I have done well and worked in the following area:**
- **Figured out how and why did they work well.**
- **How Can I make them work again.**

- **Failure: Was there a declined by 1%, where was the decline?**
- **Find things I failed. How and why they did not work.**

Improvement

- **Find the things I could do better.**
- **What First to Improve in Steps of Performance.**
- **What to Change for better Performance.**
- **Decide and Prioritise 1-3 Challenges and Problems to improve**
- **Steps I will Take To Improve.**
- **Look at the improvement over the long period of time, and decide the steps I will take to improve. Look at the improvement as marathon, where you step by step improving.**
- **Take One Step at the time to move forward.**
- **No Shortcut. Mastery does not tolerate shortcuts. Shortcuts exist to get better results with the same amount of pain/effort. It can neither scale nor work in the long term. The only way to go beyond your limitations is to do more, and better.**

Analyse

- **Find, Study and Analyse my weakness and Strengths. Work hard on my weaknesses. Perfect my strengths and work hard on my strengths.**
- **Study and Analyse the strength and weakness of the opponent or competitors and work with your weakness to their strengths.**
- **Analyse My Mistakes in Rolling.**
- **Analyse Opponent Mistakes in Rolling.**
- **Find and Analyse The Opportunity and Threat.**

Part 25: Monthly Journaling

Step 171-Materials Needed and Listen And Follow Rules of Reading For Monthly Journaling

1. Organise Materials for Journaling
 - Phone
 - Headphone
 - Pen
 - CopyBook
 - AudioRecorder on The Phone
2. Listen, Follow and Apply Rules of Reading For Journaling and Review of The Day, When Doing Journaling and Review of A Month.
3. Listen, Follow and Apply Books Throughout the Journaling, Reflection, Review, Analyse : How we Think By John Dewey,
4. Write Down Questions and Think Over the Day and Answer Those Questions, If I am Using Pen and Copybook
5. AudioRecord the Questions and Think over those questions and Answer Them.

Step 172 Record, Reflect

1. Reflection and Review.

A. Success.

- I. What I have Done Well During Month?**
- II. What Have Worked During Month?**
- III. Was There an Improvement by 1%, Where was the improvement?**

B. Failure.

- I. What I have Failed During Month?**
- II. What have not worked well During Month?**
- III. Was there a declined by 1%, where was the decline?**

C. Accountability

- I. Take Accountability for Success and Failure**

D. Visualization- Remember, visualization will never compensate for the work undone. You cannot visualize lies. All the strategies I employ to answer the simple questions and win the mind game are effective because I put in work. It's a lot more than mind over matter. It takes relentless self-discipline to schedule suffering into your day, every day, but if you do, you'll find that at the other end of that suffering is a whole other life just waiting for you.

- First, he would learn everything he could about it and prepare physically as best as possible.
- Once the physical prep was done, he'd take care of the mental prep with visualization.
- Since he knew almost everything about his challenge, he visualized what awaited him. He would imagine himself struggling, suffering, and eventually succeeding.
- Preparing himself this way helped him pace his future, and improve the odds of avoiding quitting.
- Side note: visualization is great, but it's no substitute for preparation.

Step 173-Analyse Strength and Weaknesses

1. Analyse.

- I. Find, Study and Analyse My Weakness.**
- II. Find, Study and Analyse The Opponent Weakness.**
- III. Find, Study and Analyse My Strengths.**
- IV. Find, Study and Analyse Opponent Strengths.**
- V. Work hard on my weaknesses.**
- VI. Perfect my strengths and work hard on my strengths.**

Step 174-Analyse Opportunities and Threats

1. Analyse.

- I. Find, Study and Analyse My Opportunities.**
- II. Find, Study and Analyse Opponent Opportunities I gave**
- III. Find, Study and Analyse The Threats I gave to Opponent**
- IV. Find, Study and Analyse The Threats the Opponent gave me.**

Step 175-Improvement

1. Improvement.

- I. Find the things I could do better.**
- II. What First to Improve in Steps of Performance.**
- III. What to Change for better Performance.**
- IV. No Shortcut. Mastery does not tolerate shortcuts. Shortcuts exist to get better results with the same amount of pain/effort. It can neither scale nor work in the long term. The only way to go beyond your limitations is to do more, and better**

Step 176-Steps to Take To Do Better and Improve

1. Steps to Improve.

- I. Decide and Prioritise 1-3 Challenges and Problems to improve**
- II. Steps I will Take To Improve.**
- III. Look at the improvement over the long period of time, and decide the steps I will take to improve. Look at the improvement as marathon, where you step by step improving.**
- IV. Take One Step at the time to move forward.**

Step 177-Ideas and Gratitude

1. Ideas

- I. Investigate each Ideas I have.**
- II. Decide The Ideas To Proceed.**

2. Gratitude.

- I. What I am Thankful for?**
- II. What is my Gratitude For?**

*Part 26: Weekly and Daily
Journaling*

Step 178-Materials Needed and Listen And Follow Rules of Reading For Weekly and Daily Journaling

1. Organise Materials for Journaling
 - Phone
 - Headphone
 - Pen
 - CopyBook
 - AudioRecorder on The Phone
2. Listen, Follow and Apply Rules of Reading For Journaling and Review of The Day, When Doing Journaling and Review of The Day.
3. Listen, Follow and Apply Books Throughout the Journaling, Reflection, Review, Analyse : How we Think By John Dewey,
4. Write Down Questions and Think Over the Day and Answer Those Questions, If I am Using Pen and Copybook
5. AudioRecord the Questions and Think over those questions and Answer Them.

Step 179- Record, Reflect

1. Reflection and Review.

A. Success.

- I. What I have Done Well For A Week, Today?**
- II. What Have Worked Within A week, today?**
- III. Was There an Improvement by 1%, Where was the improvement?**

B. Failure.

- I. What I have Failed on Weekly, today?**
- II. What have not worked well Within a week, today?**
- III. Was there a declined by 1%, where was the decline?**

C. Accountability

- I. Take Accountability for Success and Failure**

D. Visualization- Remember, visualization will never compensate for the work undone. You cannot visualize lies. All the strategies I employ to answer the simple questions and win the mind game are effective because I put in work. It's a lot more than mind over matter. It takes relentless self-discipline to schedule suffering into your day, every day, but if you do, you'll find that at the other end of that suffering is a whole other life just waiting for you.

- First, he would learn everything he could about it and prepare physically as best as possible.
- Once the physical prep was done, he'd take care of the mental prep with visualization.
- Since he knew almost everything about his challenge, he visualized what awaited him. He would imagine himself struggling, suffering, and eventually succeeding.
- Preparing himself this way helped him pace his future, and improve the odds of avoiding quitting.
- Side note: visualization is great, but it's no substitute for preparation.

Step 180-Analyse Strength and Weaknesses

1. Analyse.

- I. Find, Study and Analyse My Weakness.**
- II. Find, Study and Analyse The Opponent Weakness.**
- III. Find, Study and Analyse My Strengths.**
- IV. Find, Study and Analyse Opponent Strengths.**
- V. Work hard on my weaknesses.**
- VI. Perfect my strengths and work hard on my strengths.**

Step 181-Analyse Opportunities and Threats

1. Analyse.

- I. Find, Study and Analyse My Opportunities.**
- II. Find, Study and Analyse Opponent Opportunities I gave**
- III. Find, Study and Analyse The Threats I gave to Opponent**
- IV. Find, Study and Analyse The Threats the Opponent gave me.**

Step 182-Improvement

1. Improvement.

- I. Find the things I could do better.**
- II. What First to Improve in Steps of Performance.**
- III. What to Change for better Performance.**
- IV. No Shortcut. Mastery does not tolerate shortcuts. Shortcuts exist to get better results with the same amount of pain/effort. It can neither scale nor work in the long term. The only way to go beyond your limitations is to do more, and better**

Step 183-Steps to Take To Do Better and Improve

1. Steps to Improve.

- I. Decide and Prioritise 1-3 Challenges and Problems to improve**
- II. Steps I will Take To Improve.**
- III. Look at the improvement over the long period of time, and decide the steps I will take to improve. Look at the improvement as marathon, where you step by step improving.**
- IV. Take One Step at the time to move forward.**

Step 184-Ideas and Gratitude

1. Ideas

- I. Investigate each Ideas I have.**
- II. Decide The Ideas To Proceed.**

2. Gratitude.

- I. What I am Thankful for?**
- II. What is my Gratitude For?**

Part 27: Stoic and Stoicism.

Step 185-You Have Required To Do The Work For Stoicism

1. When Give Opinion on Anything, Do Not Be so Angry and Mean to Others.
2. People Need To Stop Doing By Coming Unprepared To Give Opinion On Any Subject, Without Having Good Idea Of The Literature, and Arguments Written on Topic and Theme Available To Them. The people coming unprepared and not doing any Hard Work To Have an Opinion On The Subject or Topic. When People Coming Overconfidence, which could be resulting in Lack of Preparation, Which Could Lead That Your Position can be Destroyed with Ease. They simply won't do the work required. It's easy to come home, sit on the couch, watch TV, and zone out until bedtime rolls around. But that's not going to help you get smarter.
 - A. People Who Do Not Put The Required Work: The first thing they always do is tell you what they think. When someone has an opinion about everything, they want to share it with you. They often tout stats and research as if they had an imaginary checklist of facts they need to be able to rattle off to establish themselves as an expert in a field they actually know very little about. Because they have an opinion on everything, they are quick to judge others – for their lack of opinions, for their lack of knowledge, for their lack of outrage, and the list goes on.
 - B. People who have opinions about everything barf so much noise that it's hard to find the signal. Your brain has to work overtime to figure out if they did the work to come up with their opinions themselves or if they're simply regurgitating some oped in a newspaper. Over time, opinionated people also end up in their own prisons and they try to take you with them.
 - C. The problem comes from how we see the world. Our opinions are often rooted in how we think the world should work, according to our morals, values, and principles. If we see the world through the lens of our opinions, much of what happens will not agree with us. This is feedback, and how we respond to this feedback is key.

3. How to Get Smarter Read. A lot. Warren Buffett says, "I just sit in my office and read all day." What does that mean? He estimates that he spends 80% of his working day reading and thinking. When asked how to get smarter, Buffett once held up stacks of paper and said, "Read 500 pages like this every week. That's how knowledge builds up, like compound interest." All of us can build our knowledge, but most of us won't put in the effort. "Go to bed smarter than when you woke up."
4. How Long Does it Take To Prepare:
 - A. Depend on the topic and opponent, and how much he's written.
 - B. If the opponent nothing published, then there was very little preparation to be made because I simply didn't know what to expect.
 - C. On the other hand, if the opponent has published lots of written work and have some videos. Read and what his written and videos and prepare the summaries articles, videos, and have sense where he is coming from. This can take Weeks or Months.

5. Before Preparation. The difference between the people who do the work and the people who just reel off memorized opinions is huge. When you do the work, you can answer the next question. You know when to follow the rules and when they'll get you in trouble. When I did my postgraduate I was surrounded by people who could answer the test questions. They got good grades — actually, they got *great* grades but an odd thing happened after school: a lot of those people couldn't apply their knowledge to problems they hadn't seen before. They were chauffeurs — they knew the memorized answer. They couldn't answer the next question. We're all chauffeurs in some aspects of our lives. This is why understanding your circle of competence is so critical to living a rational life.

I. Circle of Competence:

A. **Circle Of Competence**-Understanding my Circle of Competence helps to avoid problems, identify opportunities for improvement and learn from Others. Circle of Competence is simple: Each of us, through experience or study, has built up useful knowledge on certain areas of the world. Some areas are understood by most of us, while some areas require a lot more specialty to evaluate. For example, most of us have a basic understanding of the economics of a restaurant: You rent or buy space, spend money to outfit the place and then hire employees to seat, serve, cook, and clean. (And, if you don't want to do it yourself, manage.) From there, it's a matter of generating enough traffic and setting the appropriate prices to generate a profit on the food and drinks you serve—after all of your operating expenses have been paid. Though the cuisine, atmosphere, and price points will vary by restaurant, they all have to follow the same economic formula. That basic knowledge, along with some understanding of accounting and a little bit of study, would enable one to evaluate and invest in any number of restaurants and restaurant chains, public or private. It's not all that complicated. Far more important is to honestly define what we do know and stick to those areas. Our circle of competence can be widened, but only slowly and over time. Mistakes are most often made when straying from this discipline. Where should we devote our limited time in life, to achieve the most success? So, the simple takeaway here is clear. If you want to improve your odds of success in life and business, then define the perimeter of your circle of competence, and operate inside. Over time, work to expand that circle

but never fool yourself about where it stands today, and never be afraid to say “I don’t know.”

II. Two Type of Knowledge: The Max Planck and Chauffeur Test

A. The Two Types of Knowledge: The Max Planck and Chauffeur Test: How to distinguish between the two types of knowledge: real knowledge and pretend knowledge.

- The first type of knowledge is real. It can’t be bought. It can’t be copied. If you want real knowledge you need to earn it. One is Planck knowledge, the people who really know. They’ve paid the dues, they have the aptitude. You are going to have the problem in your life of getting the responsibility into the people with the Planck knowledge and away from the people with the chauffeur knowledge. Real knowledge comes when people do the work. The problem is that it’s difficult to separate the two. This is the Batesian Mimicry problem. One way to tease out the difference between Planck and chauffeur knowledge is to ask them why.
- The second type of knowledge is copied. On the surface you know the answer but you lack the understanding to show your work. Then we’ve got chauffeur knowledge. They’ve learned the talk. They may have a big head of hair, they may have fine temper in the voice, they’ll make a hell of an impression. But in the end, all they have is chauffeur knowledge. I think I’ve just described practically every politician in the United States. We have the people who don’t do the work — they pretend. While they’ve learned to put on a good show, they lack understanding. They can’t answer questions that don’t rely on memorization. They can’t explain things without using jargon or vague terms. They have no idea how things interact. They can’t predict the consequences. The problem is that it’s difficult to separate the two. This is the Batesian Mimicry problem. One way to tease out the difference between Planck and chauffeur knowledge is to ask them why.
- How To Distinguish Real Knowledge and Fake Knowledge. With journalists, it is more difficult. Some have acquired true knowledge.

Often they are veteran reporters who have specialized for years in a clearly defined area. They make a serious effort to understand the complexity of a subject and to communicate it. They tend to write long articles that highlight a variety of cases and exceptions. The majority of journalists, however, fall into the category of chauffeur. They conjure up articles off the tops of their heads or, rather, from Google searches. Their texts are one-sided, short, and— often as compensation for their patchy knowledge. The same superficiality is present in business. The larger a company, the more the CEO is expected to possess “star quality.” Dedication, solemnity, and reliability are undervalued, at least at the top. Too often shareholders and business journalists seem to believe that showmanship will deliver better results, which is obviously not the case. One way to guard against this is to understand your circle of competence. Dobelli concludes with some advice worth taking to heart. Be on the lookout for chauffeur knowledge. Do not confuse the company spokesperson, the ringmaster, the newscaster, the schmoozer, the verbiage vendor, or the cliché generator with those who possess true knowledge. How do you recognize the difference? There is a clear indicator: True experts recognize the limits of what they know and what they do not know. If they find themselves outside their circle of competence, they keep quiet or simply say, “I don’t know.” This they utter unapologetically, even with a certain pride. From chauffeurs, we hear every line except this.

III. Batesian Mimicry Problem. Batesian Mimicry: Why Copycats Are Successful.

Mimic and the Real Thing:

- A. "There's two kinds of snakes you come across. There's the Texas Coral Snake, and the Mexican Milk Snake, and they both look exactly alike. The Texas Coral Snake is dangerous, it's venomous, it can kill you in a minute. The Mexican Milk Snake can't do anything to you; it's an impostor." How is it that these two look alike? It's due to a phenomenon called Batesian Mimicry.
- B. In the 1850s, the naturalist Henry Walter Bates found a certain set of butterflies who were clearly *not* of the same species but whose wings looked almost the same to the naked eye. After thinking it over, Bates eventually figured out what was going on: While the butterflies which were toxic to potential predators (the "models") were able to operate freely and relatively unmolested, there had also developed a "mimic" population of butterflies which wasn't toxic at all, yet still went untouched! In fact, biologists eventually figured out that the more toxic and dangerous the "model" was and the more frequently they appeared in the local population, the easier it was for its "mimics" to get by! Predators simply wouldn't take the risk of mixing up the two. If there aren't as many "models" around or they aren't that dangerous, the mimics have a harder time.
- C. This is a wonderful model, and in the practical world we live in, a similar phenomenon abounds: Copycats or "pretenders to the throne" are often very effective, very convincing "mimics" of the true champions. They dress the part, they talk the talk, and they know what buttons to push. But in the end, they are merely chauffeurs. We see a very Batesian effect at work: The more impressive the "model," the more effective its mimics can be in convincing people they too are impressive, and in all the same ways. But for every Warren Buffett (just one by our count), there has been many "future" Warren Buffett's. For every Steve Jobs, there have been many "next" Steve Jobs'. In fact, sometimes even just *appearances* can be quite convincing: now-disgraced Theranos founder Elizabeth Holmes was very fond of wearing a very Steve Jobsian black turtleneck outfit. Because they can be very convincing, we must be wise enough to watch out for Batesian mimicry

— even in ourselves. This brings up an interesting, at times paradoxical, question: Who can best tell the difference between a Coral Snake and its Mimics? The Coral Snake itself. The real thing knows a fake. It's worth taking the time to work on learning all the big ideas you can find, not just the ones you want to learn. In that search, you'll find a host of big winners you didn't even know existed.

6. Preparation:

- A. While we all hold an opinion on almost everything. Have I do the work required to have an opinion on any Subject? Never allow myself to have an opinion on anything that I don't know the other side's argument better than they do. The work required to have an opinion is very hard part, have I avoid it?
 - I. I have to do the reading.
 - II. I have to talk to competent people and understand their arguments.
 - III. Never try to be biased toward any of the side, but question both side of the argument.
 - IV. Do not support any side, until all the facts are put out there, clear and obvious.
 - V. Once known all the facts then analyse both sides of the argument like William Lane Craig.
 - VI. I have to think about the key variables and how they interact over time.
 - VII. I have to listen and chase down arguments that run counter to your views.
 - VIII. I have to think about how you might be fooling yourself.
 - IX. I have to see the issue from multiple perspectives.
 - X. I have to think.
 - XI. I need to become your most intelligent critic and have the intellectual honesty to kill some of your best-loved ideas.
 - XII. Be honest with yourself and open minded. ANALYSE both side of the argument logically and see which is true logically. Means has the clear terms, premises are true, and conclusion follows from premises.
 - XIII. Never say your opinion about anything that requires the analysis of the arguments and facts. Work very bery hard to have an opinion about anything.
 - XIV. Listen very carefully other side and use ancient method *state the opposition argument in my own words and ask him/her if the argument I

stated in my own words represents correctly their argument and if I UNDERSTOOD Correctly their arguments.

XV. Never use cheap shots to win argument, like logical fallacies.

XVI. Debate and discussion is not about just win at any cost, but let other person to think about your arguments and engage with them. Second reason never use in discussion cheap shots toward other person, but be civil. Third reason is win the debate and discussion. Fourth is find the truth.

B. For Affirmative and Negative Case:

- I. Read, analyse, Research, Syntopicon and Investigate Published Work.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of My own Arguments
- II. Read Opponents Books, Articles, Newspapers, Blogs. Reading Published work. What objections he would raise against the topic and prepare the responses for each of these points.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of opponent Arguments.
- III. Watch Video. Watching Videos of the opponent. What objections he would raise against the topic and prepare the responses for each of these points.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of My own Arguments.
- IV. Listen The recording that the opposition made, in which he addresses these issues.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of My own Arguments.
- V. Talk with People who are students in his class, who can tell me, privately, insights into his thinking and character.
- VI. If that sounds like a lot of work, just say, “I don’t have an opinion on that; why don’t you tell me how you got to have such a firm one? It sounds like I could learn something.”
- VII. Another way to get smarter, outside of reading, is to surround yourself with people who are not afraid to challenge your ideas. “Develop into a lifelong self-learner through voracious reading; cultivate curiosity and strive to become a little wiser every day.”

7. Compound Knowledge- Are The Resources I will Choose Concentrating On the Expiring Information or Compound Knowledge?

- I. Are on the Resources providing expiring information?
 - A. Will you care about what you're reading in a month? In a year? In five years?
 - B. Are you focused enough on the same thing to build cumulative knowledge or are you too spread out?
 - C. What do you spend time on that's likely to change in the next few years? What's not likely to change?
 - D. What would need to happen for you to stop outsourcing organisation of information to the computer?
- II. Signs of The Information in the resources are expiring
 - A. First, it's marketed to you.
 - B. Second, lacking details and nuance, it's easily digestible. This is why it's commonly telling you what happened, not why it happened or under what conditions it might happen again
 - C. Third, it won't be relevant in a month or a year. Expiring information is one reason I stopped reading most news. It's a false map.
- III. While most of us focus on consuming information that we won't care about next month, let alone next year, focus on knowledge and companies that change very, very slowly or not at all. And because the information he was learning changed slowly he could compound his knowledge over time.
- IV. Doing his own thinking and vacuums up the details. When we don't think for ourselves it's easy to put the blame on someone else, to "pass the buck" so to speak.
- V. When we consume information that doesn't expire or expires slowly; is very detailed; and we spend time thinking about it not passing the buck, we can match patterns. This is how you learn to see what other people are missing. The longer you do this, the more advantage you get.
- VI. Just like the rest of us, Buffett's dependent on information and knowledge to make great decisions. Unlike most of us, he has a great memory—perhaps because he's not trying to outsource his memory or thinking to others.
- VII. A lot of what the snowball is about the concept of learning, and creating, and the advantage of having the information and knowing it. When I came here today one

of the things that I was thinking is that what you do is so much at the intersection, because retrieving information is different from having it already in your head.

VIII. What you do is different. You work on manipulating how you use the information.

In fact, Warren Buffett and Charlie Munger have the files in their head. That's why they aren't really out there googling all the time looking for, trying to look stuff up, because they already know it.

IX. I think a lot of the work that you do here is helpful to the ordinary person, but Warren Buffett or Charlie Munger don't need it. At the same time, the lesson that they have, which is that learning yourself, making yourself as smart as you can is extremely valid, and not just relying on a library where you can look something up all the time, because a lot of times when you need to make a decision, and you need 50 pieces of information, you need to know it then.

8. The Art of Anticipation of Objections.

- A. Analyse My Arguments, and Scrutinise The arguments by using Rules of Reading.
- B. Analyse the arguments of the opponent. Scrutinise Their arguments by using Rules of Reading.
- C. Analyse My own arguments. Scrutinise My own arguments, and the potential Loopholes in the argument by Use Rules of Reading.
- D. Use Think, Logic, Strategem, Thinking models.
- E. Write.
- F. Prepare The responses to anticipated objections that, I think the opponent will bring up.
- G. Be intellectually Prepared. This means That I need to know my arguments, so well, that nothing new can surprise me. I would also invest lots of time in knowing and know better opposite side arguments. I would read both side of the arguments, and work Hard on analysing the arguments and evidence of both sides. Doing the work required to hold an opinion means you can argue against yourself better than others can. Only then can you say, "I can hold this view because I can't find anyone else who can argue better against my view." Great thinkers, like Charles Darwin, did the work. And it's one of the biggest reasons he's buried at Westminster Abbey. While we all hold an opinion on almost everything. Have I do the work required to have an opinion on any Subject? Never allow myself to have an opinion on anything that I don't know the other side's argument better than they do. The work required to have an opinion is very hard part, have I avoid it? If that sounds like a lot of work, just say, "I don't have an opinion on that; why don't you tell me how you got to have such a firm one? It sounds like I could learn something."
- H. Doing the work required to hold an opinion means you can argue against yourself better than others can. Only then can you say, "I can hold this view because I can't find anyone else who can argue better against my view." Great thinkers, like Charles Darwin, did the work. And it's one of the biggest reasons he's buried at Westminster Abbey.
- I. Doing the work counteracts our natural desire to seek out only information that confirms what we believe we know. When Darwin encountered opinions or facts that ran contrary to his ideas, he endeavored not only to listen but also not to rest

until he could either argue better than his challengers or understand how the fact fit. Darwin did the work. It's wasn't easy, but that's the point.

- J. Have the best work ethic on daily basis. This is everyday process, and try to figure it out, the strengths and weaknesses of my position and opposing person position, This leads to the True Confidence.
- K. As Per Kobe Bryant statement: Trivial things should not be taken your attention. The attentions should be focused on things that is very important. Anything outside of the most important things in life, you should not have time for. You Should love the challenge in life, and always be curious, if you can be at the top , as these greats in that area. Always focus on one thing and not multiple things, this gives an edge and advantage over other people, who focusing on multiple things in life. The World Becomes a library to you, to be better at your craft.: Everything you see whether TV show I saw, Books, Journals, I read, whether discussion, debate I listen, people I talk to. Everything was done to try to learn to become better at the craft your focusing. When you have this point of view, then the world becomes your library to help you to become better at the craft.
- L. I Always need to ask myself: Have I done the work required to have an opinion on any Subject? Never allow myself to have an opinion on anything that I don't know the other side's argument better than they do. The work required to have an opinion is very hard part, have I avoid it? If that sounds like a lot of work, just say, "I don't have an opinion on that; why don't you tell me how you got to have such a firm one? It sounds like I could learn something."
- M. I might need to Suspend my judgement and tell them that I do not have an opinion on this specific Topic.
- N. Never Under Prepare, but Vastly Over Prepare for the Opponent and their arguments and responses
- O. Spend years in preparation, take debate class at the college or university. You need to participate in debates. You need to have mock debates, where someone play role of your opponent, and then you respond to them. You need to do reading and learn how to flow the debates. How to construct affirmative case and negative case. You need to take time to prepare and have enormous preparation.
- P. Memorize the arguments for my case

9. When Dialogue, Discussion, Debate Takes A Place.

A. As Affirmative Speaker, you need to present Prima Facie Case for proposition that is under debate. Prima Facie Case will be one that will establish the truth of proposition you are defending. If I am defending proposition that God Exist, I will want to give 3-5 arguments leading to that Conclusion, that God Exists, and then I will lay those out with great clarity in my opening speech, and say this is the groundwork for the debate. I am not interested in talking about other issues for example if Christianity bad for society Then, I come back to those in every speech over and over again. The goal is to make opponent argue on your grounds. You do not go over to his grounds, and let your audience forget, your affirmative case, rather you reorganise opponent speech, so that you answer his objections in so far as they reply to your arguments, so you may answer them in a very different order than he gave them, because you will be seeing for example: now what answer or response did he have to the cosmological argument, I see two basic responses and then you deal with them.

- Make Briefs, where I have suitable objection, and then have two or three responses to those objections.
- Use The Brief During Exchange with the Opponent. File these Briefs into Folders, and spread These Manila Folders out in front of me on Desk, When I am interacting with the Opponent. Once the opponent Rises his point I just pull These briefs from these folders and never have to think on my feet because I am completely prepared. Key is never have to think on the feet to be so well prepared, that I would have my responses ready for anything he brings up.
- Quote Peer Review Scientific Articles on the topic in support the conclusions.

B. Take Notes While the Opposition is speaking:

- How To Take Notes- Flow Chart. By Taking Notes, I am sure that I am responding to my opponent's arguments and everything he brings up.

- I. Make 11-12 Columns on the Pad. Prepare the left column in advance of the communication, debate. The Left Column needs to be filled in, if you starting first. If not, then leave left column as blank.
- II. First Left Hand Column Are My Arguments.
- III. Second Left Hand Column are Opposition Arguments and Responses to My arguments.
- IV. Third Left Column are My Responses to the Opponent responses.
- V. Fourth Left Hand Column are My Rebuttal.
- VI. Fifth Left Hand Column are Opponent Rebuttal.
- VII. Sixth Left Hand Column are my Responses to the Opponent rebuttal.
- VIII. Seventh Left Hand Column is the Final My Rebuttal.
- IX. Eight Left Hand Column is The opponent Rebuttal.
- X. Ninth Left Hand Column is my closing statements.
- XI. Tenth Left Hand Column is the opponent closing statements.
- XII. Eleventh Left Hand Column is the Cross Examination.
 - My Answer.
 - Opponent Answer.
 - My response to the response of the opponent.

C. Always Remind the audience what are your three to five arguments and what are the responses of the opponent, if any to your arguments.

D. Always allow the opponent allow to lay out his argument without interruption.

E. Take the opponent arguments and put in my own words and correctly represent their argument carefully without misrepresentation.

F. Be Honest.

G. Be Open Minded.

H. Always from Your side be honest and rigorous exchange of arguments and counter Arguments from which me and opponent would benefit.

I. One of good technique is whenever you can quote an opponent against himself, this is powerful device. Have the manuscript, point to the footnote, cite the book, and the quotation and have the page number.

J. Never Take Cheap Shots at the Opponent.

- K. Encourage not just trust someone say so, but demand published peer reviewed articles in support of the positions that one take
- L. Always look at the reality of the situation, and do not let the emotion cloud the situation and the execution. Always be in the present and the moment.

Step 186-Use Rules of Reading for Stoicism

1. Listen, Follow and Apply Rules of Reading of Bible Study, Deep Work, Deep Study, Analysis, Syntopicon and Research For Stoicism and Stoic.
 - A. **VERY VERY FAST Reading- Skimming. Pages 47-51.**
 - B. **VERY FAST READING- Entertainment.**
 - I. **Method 1-Speed Reading. FAST Reading. Pages 59-64.**
 - C. **FAST READING: Methods for Basic Knowledge For Deep Work or Bible Study.**
 - I. **Method 1-Survey, Question, Read, Recite, Record, Reflect (SQR4). Pages 66-67.**
 - II. **Method 2-Use 80/20 Principle For Reading. Pages 68.**
 - III. **Method 3-Preview, Question, Read, Summary,Test (PQRST). Page 69.**
 - IV. **Method 4-Flip Through Pages and Analyse. Page 70.**
 - V. **Method 5-Devotional Bible Study by Using Devotional Books. Pages 71-72.**
 - VI. **Method 6-Devotional Bible Read. Pages 73-74.**

D. Deep Work, Deep Study, Bible Study or Any Book- SLOW Reading- Complex Text.

- I. Method 1-Chapter Summary Method. Pages 143-147.**
- II. Method 2-Character Quality Method. Pages 148-160.**
- III. Method 3-Thematic Method. Pages 161-163.**
- IV. Method 4-Biographical Method. Pages 164-176.**
- V. Method 5-Topical Method. Pages 177-180.**
- VI. Method 6-Word Study Method. Pages 181-189.**
- VII. Method 7-Book Background Method. Pages 190-194.**
- VIII. Method 8-Book Survey Method. Pages 195-205.**
- IX. Method 9-Chapter Analysis Method. Pages 206-215.**
- X. Method 10-Paragraph Study. Pages 216-229.**
- XI. Method 11-Verse by Verse Analysis Method. Pages 230-234.**
- XII. Method 12-Book Synthesis Method. Pages 235-238.**
- XIII. Method 13-Theological Study Method of Bible Study. Pages 239-245.**
- XIV. Method 14-Studying Bible Prophecy. Pages 246-259.**
- XV. Method 15-Typological Study Method. Pages 260-262.**
- XVI. Method 16- John MacArthur Way Bible Study. Pages 263-268.**
- XVII. Method 17-Inductive Bible Study Method. Pages 269-296.**
- XVIII. Method 18-BIBLICAL HERMENEUTICS. Pages 297-302.**
- XIX. Method 19-Theological Group of Principles. Pages 303-306.**
- XX. Method 20- How To Read A Book Pages 307.**

E. VERY VERY SLOW READING- COMPLEX TEXT. Deep Work, Shallow Work, Bible Study, Analysis of Text, Research, Investigative Journalism, Investigation and Syntopicon, Mixed Method.

- I. Method 21- How To Read A Book By Mortimer Adler Various edition Pages 341.**
- II. Method 22-How To Read A Book For Various Books. Pages 342-600.**
- III. Method 23- Syntopicon Pages 601-642.**
- IV. Method 24-The Craft of Research. Pages 644-882.**
- V. Method 25-Research Books can Be Used. Pages 883-897.**
- VI. Method 26-Investigative Journalism. Pages 898-923.**
- VII. Method 27-Mixed Methods of Rules of Reading. Pages 924-942.**

2. Apply The Books To Stoicism and Stoic

Step 187-Stoic and Stoicism Books

1. Do not become victim, and looking to be victimise, That the world is owed you everything. World does not owed you anything. Work Hard, Love God, Love Your Country and Embrace Stoicism.
2. Does the Character has died as a Hero, or living long enough to become a villain. There are no Heroes in this world.
3. **Listen, Follow And Apply Rules of Reading Part 1 to 21, before looking into Stoicism and Stoic.**
4. **Listen, Follow and Apply the following Books.**
 - A. **Guide to the good life_ the ancient art of Stoic joy.**
 - B. **Dialogues and Essays By Seneca.**
 - C. Emotion and Peace of Mind_ From Stoic Agitation to Christian Temptation.
 - D. A Stoic and Socratic Guide to Life by Epictetus.
 - E. Great Books of the Western World By Mortimer Adler.
 - F. The Stoic_ Elements of Ethics, Fragments, and Excerpts By Hierocles.
 - G. How to be a stoic _ using ancient philosophy to live a modern life By Massimo Pigliucci.
 - H. How to Be Free: A Guide To Stoic Life BY Epictetus.
 - I. Letter from Stoic By Seneca.
 - J. Meditation By Marcus Aurelius.
 - K. Meditation on Discipline and Failure By Ferraiolo.
 - L. One True Life By Kevin Rowe.
 - M. Pursuits of Wisdom_ Six Ways of Life in Ancient Philosophy from Socrates to Plotinus.
 - N. Stoic Logic By Benson Mates.
 - O. The Philosophy of Cognitive Behavior Therapy: Stoic Philosophy and Rational.
 - P. Stoic Pack.
 - Q. Stoic Warriors_ The Ancient Philosophy Behind the Military Mind.
 - R. Stoicism and Emotion.
 - S. Stoicism and the Art of Happiness_ A Teach Yourself Guide.
 - T. Stoicism Today_ Selected Writings (Volume Two).
 - U. Stoicism a Beginners guide to Stoicism.
 - V. Stoic Notes.

W. The Stoics: A GUIDE FOR PERPLEXED.

X. Stoicism.

Y. The Art of Living_ The Stoics on the Nature and Function of Philosophy.

Z. Cambridge Companion to STOICS.

AA.The Daily Stoic_ 366 Meditations on Wisdom, Perseverance, and the Art of Living

BB.The Little Book of Stoicism_ Timeless Wisdom to Gain Resilience, Confidence,
and Calmness.

CC.ROUTLEDGE HANDBOOK TO STOIC TRADITION.

DD.Sniper Mind.

EE.The Stoic Life_ Emotions, Duties, and Fate.

FF. Stoic Sage.

GG.Stoics On Ambiguity.

HH.The Wisdom of the Stoics_ Selections from Seneca, Epictetus and Marcus
Aurelius.

II. The Stoics.

Step 188- Thinking, Logic and Mental Model

1. Listen, Follow and Apply Thinking, Logic and Mental Model PART 7

Part 7: Thinking, Logic and Mental Model For Deep Work or Deep Study, Or Bible Study

- 1. Step 57- Slow Down. Pages 1061-1063.**
- 2. Step 58- NOT MULTITASK. Pages 1064.**
- 3. Step 59-You Have Required To Do The Work For Thinking and Applying Mental Tool Models. Pages 1065-1080.**
- 4. Step 60-Why Critical Thinking, Logic, Thinking and Mental Tools Are Important? Pages 1081-1083.**
- 5. Step 61-Intradisciplinary Thinking. Pages 1084-1125.**
- 6. Step 62-Multidisciplinary Thinking. Pages 1126-1168.**
- 7. Step 63-CrossDisciplinary Thinking. Pages 1169-1211.**
- 8. Step 64-Interdisciplinary Thinking. Pages 1212-1254.**
- 9. Step 65-Transdisciplinary Thinking. Pages 1255-1298.**
- 10. Step 66-Journaling. Pages 1299.**
- 11. Step 67-Letting The World Do The Work For You. Pages 1300-1305.**
- 12. Step 68-Journaling. Pages 1306.**
- 13. Step 69-Letting The World Do The Work For You. Pages 1307-1312.**

Step 189-Journaling

1. **Step 1-So keep a journal. Write your experiences down. When you identify a model at work in the world, write that down too. Then you can explore the applications you've observed, and start being more in control of the models you use every day. For instance, instead of falling victim to confirmation bias, you will be able to step back and see it at work in yourself and others. Once you get practice, you will start to naturally apply models as you go through your life, from reading the news to contemplating a career move. As we have seen, we can run into problems when we apply models to situations in which they don't fit. If a model works, we must invest the time and energy into understanding why it worked so we know when to use**
2. **Visualization- Remember, visualization will never compensate for the work undone. You cannot visualize lies. All the strategies I employ to answer the simple questions and win the mind game are effective because I put in work. It's a lot more than mind over matter. It takes relentless self-discipline to schedule suffering into your day, every day, but if you do, you'll find that at the other end of that suffering is a whole other life just waiting for you.**
 - **First, he would learn everything he could about it and prepare physically as best as possible.**
 - **Once the physical prep was done, he'd take care of the mental prep with visualization.**
 - **Since he knew almost everything about his challenge, he visualized what awaited him. He would imagine himself struggling, suffering, and eventually succeeding.**
 - **Preparing himself this way helped him pace his future, and improve the odds of avoiding quitting.**
 - **Side note: visualization is great, but it's no substitute for preparation.**

Step 190-Letting The World Do The Work For You

1. Listen and Apply book
 - I. This Explains Everything_ Deep, Beautiful, and Elegant Theories of How the World Works
2. **The world never tells you that you're wrong; it only gives you outcomes.**
3. **Don't force. Don't resist. Have a beginner's mind. Let the world teach you.**
4. **Reality will do a lot of the work for us if we simply align with it. Most of the time we're simply adding friction because we want the world to work in the way we think it should.**
5. **If you don't see the world the way it is, you'll think it works in a way that it doesn't and make terrible mistakes. The key to getting what you want out of life is to identify how the world works and align yourself accordingly. This is hard because we think the world should work the way we see it. The word "should" is important. Because we think the world should work in a way that it doesn't, our approach is suboptimal. What the pupil must learn, if he learns anything at all, is that the world will do most of the work for you, provided you cooperate with it by identifying how it really works and aligning with those realities. If we do not let the world teach us, it teaches us a lesson. Joseph Tussman**
6. When an outcome is not what you want it to be, things get tough. You can ignore the result and continue to think that you're right. This protects your ego. It also carries the risk of your continuing to believe something that isn't true. Alternatively, you can calibrate your believability on the subject at hand by lowering the odds that you're right. For example, maybe you gave yourself an 85 out of 100 for the ability to hold a firm opinion on this subject, and now you lower your score to 75. If the world continues to provide undesirable outcomes, eventually you get the hint and change your beliefs. Finally, you can give up your opinions and just respond to the world as it is. This option is the hardest.
7. You do not create the way the world works, you can only align yourself with it. It takes a lot of work to align ourselves with reality. When we don't get the outcome we're seeking, the last place we look is inside ourselves. Instead, we blame others or

circumstances. If you want to align yourself with reality, you have to work at it and care about it. There are two keys to aligning yourself with how the world really works: accepting feedback and stopping bargaining.

- I. We let people, not results, guide our behavior. The world tries to tell us when we don't see it the way it is. The problem is we don't listen to the world. Instead, we let others tell us what's right and wrong, what works, and what doesn't. Common actions get common results. Most of our actions come from others. We want what they want. Even worse, we employ the same actions to get it. This isn't always wrong. If you're just starting, the quickest path to average is to copy. If you want better results than average, you're going to have to iterate. Doing something different means we might look like a fool, and we do not want to look like a fool. Iterating means trying something new, it means you might fail. Show me a person who's afraid to look bad, and I'll show you a person you can beat every time. If we do what everyone else is doing, we're going to get the same results that everyone else is getting. Different results demand different actions. If you can't really fail, you can't really succeed. Let results, not popularity, determine your actions. If you're doing something that doesn't get you the results you want, try something new. If you're doing something that seems to work, keep doing it. Consistently repeat successful actions.
- II. Bargaining with the world doesn't work. A lot of otherwise smart people know what they're doing isn't getting the results they want, but because they think the world *should* work in a way that it doesn't, they keep repeating them hoping for different results. If you are this person, see it for what it is, and change your actions. The feedback from the world is often painful. Often, it is this very pain that causes us to no longer delude ourselves with how the world should work and accept how it does work. If you can learn to accept the world for how it is, before suffering, you'll go faster and further. Outcome over ego. If you think you know how the world works but you're doing something that gets suboptimal results because it *should* work a different way, you don't really know how the world works. Rational people take feedback from the world. If you want to know how someone sees the world, look at their actions. In the end, it's all your fault. You are accountable for your outcomes. When you take responsibility for your outcomes, you naturally accept feedback from reality. When you get feedback from reality, you adjust your behavior.

- III. As Per Kobe Bryant statement: Trivial things should not be taken your attention. The attentions should be focused on things that is very important. Anything outside of the most important things in life, you should not have time for. You Should love the challenge in life, and always be curious, if you can be at the top , as these greats in that area. Always focus on one thing and not multiple things, this gives an edge and advantage over other people, who focusing on multiple things in life. The World Becomes a library to you, to be better at your craft.: Everything you see whether TV show I saw, Books, Journals, I read, whether discussion, debate I listen, people I talk to. Everything was done to try to learn to become better at the craft your focusing. When you have this point of you, then the world becomes your library to help you to become better at the craft.
- IV. Have the best work ethic on daily basis. This is everyday process, and try to figure it out, the strengths and weaknesses of my position and opposing person position.
- V. Always look at the reality of the situation, and do not let the emotion cloud the situation and the execution. Always be in the present and the moment.
- VI. If you understand the world as it really is, not as you'd wish it to be, you will begin to make better decisions almost immediately. Once you start making better decisions the results compound. Better initial decisions free up your time, reduce your stress, allowing you to spend more time with your family and leave your competition in the dust.
- VII. How can we best understand the world as it is? Acquiring knowledge can be a very daunting task. If you think of the mind as a toolbox, we're only as good as the tools at our disposal. A carpenter doesn't show up to work with an empty toolbox. Not only do they want as many tools in their toolbox as possible, but they want to know how to use them. Having more tools and the knowledge of how to use them means they can tackle more problems. Try as we might, we cannot build a house with only a hammer. If you're a knowledge worker, you're a carpenter. But your tools aren't bought at a store and they don't come in a red box that you carry around. Mental tools are the big ideas from multiple disciplines, and we store them in our mind. And if we have a lot of tools and the knowledge required to wield them properly, we can start to synthesize how the world works and make better decisions when confronted with problems.
- VIII. This is how we understand and deal with reality. The tools you put into your toolbox are Mental Models. Mental models are a framework for understanding

how the world really works. They help you grasp new ideas quickly, identify patterns before anyone else and shift your perspective with ease. Mental Models allow us to make better decisions, scramble out of bad situations, and think critically. If you want to understand reality you must look at a problem in multiple dimensions — how could it be otherwise? Getting to this level of understanding requires having a lot of tools and knowing how to use them. You knew there was a hitch right? We need to change our fast-food diet of information consumption and adopt the healthier diet of knowledge that changes slowly over time. While changing diets isn't easy, it can be incredibly rewarding: more time, less stress, and being better at your job. The costs, however, are short term pain for long-term gain. You must change how you think.

- IX. 2nd Order Thinking. One example of a model we can immediately conceptualize and use to improve our ability to make better decisions is something we can borrow from ecology called second-order thinking. The simple way to conceptualize this is to ask yourself "If I do X, what will happen *after* that?". I sum this up using the ecologist Garrett Hardin's simple question: "And then what?" A lot of people forget about higher order effects — second and third-order effects or higher. I've been in a lot of meetings where decisions are made and very few people think to the second level, let alone the third. Rather, what typically happens is called first conclusion bias. The brain shuts down and stops thinking at the first idea that comes to mind that seems to address the problem as you understand it. We don't often realize that our first thoughts are usually not even our own thoughts. They usually belong to someone else. We understand the sound-byte but we haven't done the hard work of real thinking. After we reach the first conclusion, our minds often shut down. We don't seek evidence that would contradict our conclusion. We don't ask ourselves what the likely result of this solution would be — we don't ask ourselves "And then what?" We don't ask what other solutions might be even *more* optimal. For example, consider a hypothetical organization that decides to change their incentive systems. They come up with a costly new system that requires substantial changes to the current system. Only they don't consider (or even understand) the problems that the *new* system is likely to create. It's possible they've created more problems than they've solved — only now there are *different* problems they must put their head down to solve. Optically, they "reorganize their incentive programs," but practically, they've simply expended energy to stay in place. Another, perhaps more complicated,

example is when a salesman comes into a company and offers you a software program he claims will lower your operating costs and increase your profits. He's got all these beautiful charts on how much more competitive you'll be and how it will improve everything. This is exactly what you need because your compensation is based on increasing profits. You're sold. Then second-order thinking kicks in and you dare to ask how much of those cost savings are going to go to you and how much will eventually end up benefits enjoyed by customers? To a large extent, that depends on the business you're in. However, you can be damn sure the salesman is now knocking on your competitor's door and telling them you just bought their product and if they want to remain competitive they better purchase it too. Eventually, you all have the new software and no one is truly better off. Thus, in the manner of a crowd of people standing on their tip-toes at a parade, all competitors spend the money but none of them win: The salesman wins and the customer wins. We know, thanks to people like Garrett Hardin, Howard Marks, Charlie Munger, Peter Kaufman, and disciplines like ecology, that there are second and third-order effects. This is how the world really works. It just isn't always a comfortable reality. Understanding how the world works isn't easy and it shouldn't be. It's hard work. If it were easy, everyone would do it. And it's not for everyone. Sometimes, if your goal is to maximize utility, you should focus on getting very, very good in a narrow area and becoming an expert, accepting that you will make many mistakes outside of that domain. But for most, it's extremely helpful to understand the forces at play outside of their narrow area of expertise. Because when you think about it, how could reality be anything other than a synthesis of multiple factors? How could it possibly be otherwise?

- X. When our mental models line up with reality, they help us avoid problems. However, they also cause problems when they don't line up with reality as we think something that isn't true.
- XI. We must be open to other perspectives if we truly want to understand the results of our actions. Despite feeling that we've got all the information, if we're on the ship, the fish in the ocean has more he can share. The second flaw is ego. Many of us tend to have too much invested in our opinions of ourselves to see the world's feedback—the feedback we need to update our beliefs about reality. This creates a profound ignorance that keeps us banging our head against the wall over and over again. Our inability to learn from the world because of our ego happens for many reasons, but two are worth mentioning here. First, we're so

afraid about what others will say about us that we fail to put our ideas out there and subject them to criticism. This way we can always be right. Second, if we do put our ideas out there and they are criticized, our ego steps in to protect us. We become invested in defending instead of upgrading our ideas. The third flaw is distance. The further we are from the results of our decisions, the easier it is to keep our current views rather than update them. When you put your hand on a hot stove, you quickly learn the natural consequence. You pay the price for your mistakes. Since you are a pain avoiding creature, you update your view. Before you touch another stove, you check to see if it's hot. But you don't just learn a micro lesson that applies in one situation. Instead, you draw a general abstraction, one that tells you to check before touching anything that could potentially be hot. Organizations over a certain size often remove us from the direct consequences of our decisions. When we make decisions that other people carry out, we are one or more levels removed and may not immediately be able to update our understanding.

Part 28: Learning.

Step 191-Books For Studies

1. **Listen, Follow And Apply Rules of Reading Part 1 to 22, before looking into Learning.**
2. **How To Read A Book By Mortimer Adler for Various Editions**
3. **Listen, Follow and Apply the following Books.**
 - A. **How to Study by Ron Fry**
 - B. **Learning How to Learn.**
 - C. **Learning to Read Critically in Teaching and Learning.**
 - D. **Polyglot.**
 - E. **The Well Educated Mind.**
 - F. **The Well Trained Mind.**
 - G. **A Well Educated Mind/**
 - H. **Trivium: Liberal Arts of Logic, Grammar and Rhetoric by Miriam Joseph**
 - I. **Quadrivium: The Four Classical Liberal Arts of Number, Geometry, Music and Cosmology.**
 - J. **Trivium 21 C Preparing Young People For The fUTURE WITH IESSONS fROM THE Past. By Martin Robinson**
 - K. **Final Trivium- Learning Skills**
 - L. **UltraLearning.**
 - M. **Deep Work.**
4. **Listen, Follow and Apply The following Books on Discussion.**
 - A. **Tactics By Greg Koukl**
 - B. **Tactics and Socratic Method.**
 - C. **Socratic Method By Rebecca Cain.**
 - D. **Plato Euthyphro**
 - E. **Socrates Guide for Preplexed**
 - F. **Socrates way.**
 - G. **Plato Complete Work.**
 - H. **Socratic Method In the classroom.**
 - I. **The Power of Socratic Classroom.**
 - J. **Thinker Guide to Socratic Questioning.**
 - K. **Teaches Like Socrates Guide.**

L. Socratic method Today.

5. Trivium: Listen, Follow and Apply The following Books on Discussion.

A. Grammar

- **The Cambridge Grammar of The English Language B Rodney Huddleston.**
- **Any Grammar that Teaches grammar to children from beginner to Most Advanced.**

B. Logic

- **A Concise Introduction to Logic By Patrick Hurley**
- **Any Logic Book that teaches children Logic**
- **Aristotle on Logic**
- **Material Logic**
- **Traditional Logic**
- **Socratic Logic By Peter Kreeft**

C. Rhetoric

- **Rhetoric By Aristotle**
- **On Rhetoric By Aristotle**
- **Art of Rhetoric By Aristotle**

D. Reading

- **How To Read A book by Mortimer Adler 1940 Edition**
- **How to Read A Book by Mortimer aDLER 1966 eDITION**
- **How To read A Book by Mortimer Adler 1972 Edition**

Step 192 - Classical Education Curriculum

Books For Classical Education Curriculum

- **Ambrose Curriculum Guide**
- **Classical Curriculum**
- **Classical Education**
- **ICE_PSE- An Introduction to classical Education**
- **Rhetoric Booklet**
- **The Educational Plan**
- **Trivium**
- **What is Classical Education**
- **How to study**
- **UltraLearning.**
- **Deep Work**

Study in Classical Education For Curriculum:

- **Socratic Questioning, Socratic Method and Socratic Discussion.**
- **Use Plato Dialogue for Socratic Method, Socratic Questioning and Socratic Discussion.**
- **UltraLearning.**
- **Deep Work**
- **Trivium**
 - I. **Logic (Aristotelian Logic) and Then Hard Mathematical Logic**
 - II. **Grammar**
 - III. **Rhetorics**
- **Quadrivium**
 - I. **Arithmetic**
 - II. **Music**
 - III. **Geometry**
 - IV. **Astronomy**

- **Fine Art**

- I. **Architecture**
- II. **Sculpture**
- III. **Painting**
- IV. **Literature**
- V. **Music**
- VI. **Performing**
- VII. **Film**

- **Science-Moral**

- I. **Literature**
- II. **History**
- III. **Philosophy**

- **Science- Natural**

- I. **Physical**
- II. **Earth**
- III. **Life**

- **Reason**

- **Critical Thinking, Thinking and Thinking in Models**

- **Classical Language: Latin, Greek, Hebrew, Arabic**

- **Languages: English, Lithuanian, Ukrainian, French, Spanish, Portuguese, Chinese.**

- **Speech-As Parent I need to find a way that My children would stand up and speak in front of other people, and Give them all the tools necessary.**

- **How To Put Ideas into Practice. How The Idea can be put into practice.**

6. Introduce Alexandra and Adelina to Good Literature:

- **Have A Deep Literature Hour with Both of them**

7. When Reading with Alexandra and Adelina, ask Question:

- **What**
- **Who**
- **When**
- **Where**
- **Why**
- **How**

- What does the text Says?
- What does the author mean based on text?
- Lets try to find what does the author mean by writing this
- Use Rules of Reading.

Step 193 - UltraLearning.

Summary

CHAPTER 1: CAN YOU GET AN MIT EDUCATION WITHOUT GOING TO MIT?

- His friend's advice: ***always have a challenge***

CHAPTER 2: WHY ULTRALEARNING MATTERS

- **Ultralearning**: a strategy for acquiring skills that is both *self-directed* and *intense*
 - Ultralearning is a powerful tool and a small investment
 - Rapidly learning hard skills can have a greater impact than years of mediocre striving on the job
- Your deepest moments of happiness don't come from easy things. They come from realizing your potential and overcoming your own limiting beliefs about yourself
- Medium-skilled technical work is being outsourced overseas or replaced with technology. Only high-skilled jobs and lower-skilled jobs are remaining due to developing technology
 - You need to move to the higher-skilled category where *learning is constant*, or you'll be pushed into the lower skilled category
- Ultralearning can fill in the gaps where higher education does not fill the need in the market and is also *more flexible* to the students lifestyle demands

Reader's note: this reminds me a lot of the argument for learning things quickly and efficiently as referenced in the book [Deep Work by Cal Newport](#)

- The best ultralearners are those who blend the practical reasons for learning a skill with an inspiration that comes with something that excites them
 - Learning and growth also *builds your confidence* and brightens your perspective of what's possible

CHAPTER 3: HOW TO BECOME AN ULTRA LEARNER

- What makes ultra learning interesting is also what makes it hard to boil down into step-by-step formulas

Principles of becoming an ultralearner:

1. **Metalearning** – *first draw a map*
2. **Focus** – *sharpen your knife*. Cultivate the ability to concentrate
3. **Directness** – *go straight ahead*
 - Learn by doing the thing you want to become good at
4. **Drill** – *attack your weakest point*
 - Be ruthless in improving your weakest points
5. **Retrieval** – *test to learn*
6. **Feedback**– *don't dodge the punches*
7. **Retention** – *don't fill a leaky bucket*. Understand what you forget and why
8. **Intuition**– *dig deep before building up*
 - Develop through play and exploration of concept and skills. Understand how understanding works
9. **Experimentation** – *explore outside your comfort zone*

CHAPTER 4: PRINCIPLE ONE – METALEARNING: FIRST DRAW A MAP

- **Metalearning** means *learning about learning*, such as how knowledge is structured and acquired within the subject
- People who speak other languages can pick up new languages more quickly
 - Also people who study new languages are more familiar with language acquisition
- Break down metalearning you do for a specific project into three questions:
 - Why
 - What
 - How
- Do your research first. Determine if learning a topic is likely to have a the effect you want it to before you get started
- Two ways to answer “how” you’ll learn something:
 - **Benchmarking** – finding the common ways people learn a subject to design a default strategy as a starting point
 - **Emphasize-exclude method** – finding the areas most relevant to your learning goals and excluding those that aren’t from your curriculum
- Rule of thumb: invest about 10% of your total expected learning time in research before you get started
- The true benefits of metalearning are long-term

CHAPTER 5: PRINCIPLE TWO – FOCUS: SHARPEN YOUR KNIFE

- In the realm of great intellectual accomplishments, an *ability to focus quickly and deeply* is nearly ubiquitous
- The struggles with focus that people have generally come in three broad varieties:
 - Starting
 - Sustaining
 - Optimizing the quality
- Ultralearners are relentless in coming up with solutions to handle these 3 problems which form the basis of an ability to *focus well* and *learn deeply*

Problem 1: Failing to start focusing a.k.a. Procrastinating

- Make a mental note when you are procrastinating, either recognizing the feeling some *desire to not do a task* or *stronger urge to do something else*
 - Building this awareness is the first step
- Sometimes the worry about the unpleasantness of a task only lasts a few minutes before going away
- One crutch is to get yourself to continue for only 5 minutes
 - After a while, you can utilize the [Pomodoro Technique](#) to further improve productivity
 - 1 pomodoro = 25 minute work sessions followed by a 3-5 minute break
 - After 4 pomodoros, take a 15-30 minute break

Problem 2: Failing to sustain focus a.k.a. Getting distracted

- **Flow** is a state of mind where you are in the zone and stop being distracted by interrupting thoughts
 - Your mind becomes *completely absorbed* in the task at hand
 - While flow may be possible in ultralearning, the environment of deliberate practice is not conducive because the difficulty makes flow very difficult
 - Additionally, the self-consciousness that is absent in flow may need to be present in ultralearning and deliberate practice as you need to constantly adjust your approach
 - His advice: ***don't worry about flow***
- Some research says breaking up studying into chunks of different subjects may help with focus
 - A proper balance is needed. *50-60 minutes* is a good length of time for many learning tasks
 - For more concentrated schedules, you can use *several-minute breaks* every hour and split up the different areas in your subject
- Ultimately, however, you need to find what works best for you
- 3 sources that causes focus to break down:
 - *Your environment*
 - Be aware, test your environment, and experiment
 - *Your task*

- Consider the different tools for learning
- Consider slight modifications in learning that increase difficulty to make it cognitively harder to zone out
- *Your mind* – negative emotions, restlessness, daydreaming
 - A clear, calm mind is always best for focusing on all learning problems
 - Dealing with problems may need to be dealt with first
 - For things you cannot control, acknowledge and be aware of your negative feelings, then let it pass

Problem 3: Failing to create the right kind of focus

- This deals with the *quality* and *direction* of your attention
- How you should apply your attention deals with two variables:
 - **Arousal** – your overall feeling of energy and alertness
 - This is caused by the sympathetic nervous system activation
 - Mentally, arousal also includes *attention*
 - High arousal creates a feeling of keen alertness, which is often characterized by feeling a narrow focus, but one that can also be somewhat brittle
 - **Task complexity**
 - More complex tests such as math problems or writing an essay tend to benefit from a *more relaxed* kind of focus
 - The space of focus is often larger and more diffuse
 - This has advantages when an order is the solve the problem you must consider many different inputs and ideas
 - Some tasks may require this *mental quietness*
 - Some particularly creative tasks may benefit from no focus at all and taking a break from the problem to allow for eureka moments
 - This however only occurs when one has focused on a problem for long enough that the breakthrough can occur in a relaxed state
 - Consider optimizing your arousal levels to sustain the ideal level of focus
 - **Complex tasks** may benefit from *lower arousal*, so working in a quiet room may work
 - **Simpler tasks** might benefit from a *noisier environment* like working at a coffee shop

CHAPTER 6: PRINCIPLE THREE – DIRECTNESS: GO STRAIGHT AHEAD

- **Directness** is the hallmark of most ultralearning projects
 - His example approach is to show that the learning activities are always *done in connection to the context* in which the skills learned will eventually be used
 - The easiest way to learn directly this is simply do the thing you want to get good at
 - This won't work for all projects, but it is something you can gradually increase to improve your performance
- Studies over decades show that general transfer of knowledge in one area into another doesn't exist and general discipline as a muscle is not a valid concept
 - However, one researcher says the **transfer** is paradoxical
 - "When we want it, we don't get it. Yet it occurs all the time"
 - Transfer tends to be harder when our knowledge is more limited
 - As we develop more knowledge and skill in one area, they become more flexible and easier to apply outside the narrow context which they were learned
 - His own hypothesis as an explanation for the transfer problem: *most formal learning is woefully indirect*
- Initial learning efforts often stick stubbornly to the *situations we learn them in*
 - The problem is that learning directly is hard
 - It is often more frustrating, challenging, and intense than reading a book or attending a lecture
 - But this very difficulty creates a potential source of *competitive advantage* for any would-be ultralearner

Learning Tactics

- Tactic 1: *project-based learning*
- Tactic 2: *immersive learning*
- Tactic 3: *the flight simulator method*
- Tactic 4: *the overkill approach*
 - Put yourself in an environments where the *demands will be extremely high* so you're unlikely to miss any important lessons or feedback

CHAPTER 7: PRINCIPLE FOUR – DRILL: ATTACK YOUR WEAKEST POINT

- Benjamin Franklin's mastery of writing is what made him great
 - It was how he practice, the way he decided to *break apart the skill of writing* and *practiced its elements in isolation* which allowed him to apply this mastery to other pursuits
- There are **rate-determining steps** in learning anything that acts as a bottleneck and determines your overall performance
 - **Drills** allow you to improve these rate-determining step in isolation which will improve your overall performance
- A **direct-then-drill approach** is first trying to practice a skill directly, then analyze the direct skill and try to isolate components that are either rate-determining steps in your performance, or sub-skills you find difficult to improve because there are too many other things going on for you to focus on them
 - The final step is to go back to direct practice and integrate what you've learned

Drills

- Drill 1: *Time slicing* – Isolate a slice in time of the longer sequence of actions
- Drill 2: *Cognitive components*
- Drill 3: *The copycat* – Copy the aspects you don't want to drill so that you can isolate the aspects you do, such as copying a painting from someone else but practicing one aspect component
- Drill 4: *The magnifying glass method* – spend more time on one component of the scale than you would otherwise
- Drill 5: *Prerequisite chain* – start on hard skills and learn prerequisite foundational skills as needed, which saves time from learning sub skills that don't drive performance

Reader's note: this section of drilling reminds me of the idea of removing the bottleneck to improve the overall performance of a system from the book [The Goal by Eliyahu Goldratt](#)

- Drilling is difficult, but something *mentally strenuous provides a greater benefit* to learning than some thing easy

CHAPTER 8: PRINCIPLE FIVE – RETRIEVAL: TEST TO LEARN

- Study showed *testing yourself*, trying to retrieve information without looking at the text, aka **free recall** or **self-testing**, clearly outperformed both simple review and concept mapping methods
 - This might be because:
 1. You get feedback
 2. Self-testing is more directly related to actual testing and therefore transfer is more likely
- Increasing the difficulty and testing yourself way *before you are ready* is more efficient compared to low-intensity learning strategies which involve less or easier retrieval
 - Giving a test later when information is not top of mind improves retention because it is more difficult
 - However, testing too late so that you forgotten the information entirely is not beneficial
 1. You need to find a good midpoint
- The concept of **forward retrieval** is that early testing may help for retrieval later on for information not yet learned
- Nearly any fact or concept is now available to anyone with a smart phone. However this hasn't made the modern person thousands of times smarter than before
 - Being able to look things up is certainly an advantage, but without a certain amount of knowledge inside your head, it doesn't help you solve hard problems

Useful methods to apply retrieval to almost any subject

1. *Flashcards*
2. *Free recall*
3. *The question book method* – rephrase your recorded notes as questions to be answered later
 - What's harder and more useful is to restate the big idea of a chapter or section as a question because it requires deeper thinking
4. *Self-generated challenges*
5. *Closed book learning*

CHAPTER 9: PRINCIPLE SIX – FEEDBACK: DON'T DODGE THE PUNCHES

- The ability to gain immediate feedback on one's performance is an essential ingredient in reaching expert levels of performance
- The type of feedback is important
 - Feedback works well when it provides useful information that can guide future learning such as what you were doing wrong and how you can fix it
 - However, feedback often backfires when it is *aimed at a person's ego*
 - **Praise**, for example, is usually harmful to further learning
 - When feedback steers into an evaluation of you as an individual, it usually has a *negative impact on learning*
- Ultralearners need to be sensitive to what feedback that is actually useful and tune out the rest
- **Fear of feedback** often feels more uncomfortable than experiencing the feedback itself
 - It is not so much negative feedback on its own that can impede progress, but the fear of hearing criticism that causes us to shut down
 - Sometimes the best action is to dive straight into the hardest environment which can reduce your fears of getting started initially
 - It will allow you to adjust accordingly if the feedback is too harsh to be useful
- Three types of feedback:
 - *Outcome feedback*
 - *Informational feedback*
 - *Corrective feedback*
- **Outcome feedback** tells you how you are doing overall, but not what you're doing right or wrong, why, or how to improve
- **Informational feedback** can tell you what you are doing wrong, but not how to fix it
 - This is easy to obtain when you can get live, real time feedback like an audience's reaction
- **Corrective feedback** is the best type of feedback because it can show you what you're doing wrong and how to fix it
 - This type is typically only available through a coach, mentor, or teacher, or certain studying tools
- The best **feedback** is *informative* and *usable* by the student who receives it
 - Optimal feedback *indicates the difference between the current state and the desired state*, and helps students *take a step to improve their learning*
- Research shows that *immediate feedback* is superior in regards to timing
- Trying to avoid situations that always make you feel good or bad about your performance
 - Sometimes is the easiest way to improve feedback is simply to get a lot more of it a lot more often
- Though short-term feedback can be stressful, once you get into the habit of receiving it, it becomes easier to process without overreacting emotionally

CHAPTER 10: PRINCIPLE SEVEN – RETENTION: DON'T FILL A LEAKY BUCKET

- **Memory** is essential to learning things well
 - In terms of memory, *our minds are a leaky bucket*
 - But most of the holes are at the top so the water that remains at the bottom leaks out more slowly
 - We tend to forget information quickly but then it tapers off after a while
- Four mechanisms of retention:
 - Spacing
 - Proceduralization
 - Overlearning
 - Numonics
- **Spacing** learning sessions over more intervals across a longer periods of time helps with *long-term retention*, though lower performance in the short-term because of forgetting
 - Another strategy for applying spacing is to semi-regularly do refresher projects
- **Procedural information** tends to be stored for much longer so it may benefit to you practice a core set of information instead of everything evenly
 - Not all skills can become automatic and proceduralized
- **Overlearning** is additional practice beyond what is required to perform adequately which can *increase the length of time* that memory is stored
- **Numonics** – a picture retains 1000 words
 - Book reference: [Moonwalking with Einstein by Joshua Foer](#)

CHAPTER 11: PRINCIPLE EIGHT – INTUITION: DIG DEEP BEFORE BUILDING UP

Useful guidelines for doing things differently:

1. *Rule one:* don't give up on hard problems easily
2. *Rule two:* prove things to understand them. Working through things yourself can help you develop the capacity for deep intuition
3. *Rule three:* always start with a concrete example
4. *Rule four:* don't fool yourself. Explaining things clearly and asking dumb questions can keep you from fooling yourself into thinking you know something you don't
- **The Feynman Technique:**
 - First, write down the problem or concept you want to understand at the top of the paper
 - Second, in the space below, explain the idea as if you had to teach it to someone else or convey the idea to someone who's never heard of it
 - Explain how to solve it and why the procedure makes sense
 - Third, when you get stuck and your understanding fails to provide a clear answer, go back to your reference material to find your answer

Reader's note: This concept is just like teaching in order to understand and learn better

CHAPTER 12: PRINCIPLE NINE – EXPERIMENTATION: EXPLORE OUTSIDE YOUR COMFORT ZONE

- **Variation** is important to finding style or method that works for you
 - Find one that will take advantage of your strengths and diminish your weaknesses, just like what Van Gogh did
 - *Aggressive exploration* and *tenacity* we're also key to Van Gogh's success
- **Experimentation** is the key to mastery
 - As you approach mastery, many skills reward *proficiency* as well as *originality*
 - As ***creativity becomes valuable, experimentation becomes essential***
- Three types of experimentation:
 - Experimenting with *learning methods, materials, and resources*
 - Experimenting with *technique*
 - Experimenting with *style*
- The key to experimenting with different styles is to be aware of all the different styles that exist

The mindset to experimentation

- Experimentation requires a **growth mindset**, as referenced by psychologist Carol Dweck
 - Book reference: [Mindset by Carol Dweck](#)
- How to experiment:
 - *Copy then create*
 - *Compare methods side-by-side*
 - *Introduce new constraints* – The best innovations come from working within constraints
 - *Find your superpower in the hybrid of unrelated skills*
 - *Explore the extremes*

CHAPTER 13: YOUR FIRST ULTRALEARNING PROJECT

- **Step one:** do your research
 - Ultralearning “packing” checklist:
 1. What *topic* you’re going to learn and it’s *approximate scope*. He suggest starting with a narrow scope and expanding it as needed
 2. The *primary resources* you’re going to use
 3. A *benchmark* for how others I have successfully learned this skill or subject
 4. Direct practice *activities*
 5. Back up *materials* and *drills*
- **Step two:** schedule your time
 - Consistency breeds good habits, reducing the effort required to study
- **Step three:** execute it
- **Step four:** review your results
- **Step five:** choose to maintain or master what you’ve learned
 - If you want to maintain your skills, schedule in time to practice it every so often or try to integrate your new skills into your life somehow
 - Sometimes the *cost of re-learning a skill* is smaller than the cost of keeping it continuously sharp
 1. One reason may be you might have learned more than you actually need. Also, *re-learning* is generally easier than first time learning

Alternatives to ultralearning: Low intensity habits and formal instruction

- Being an ultralearner doesn’t imply that everything one learns has to be done in the most aggressive and dramatic fashion possible
- Two main alternative strategies to ultralearning to see how they fit into a *bigger picture of lifelong learning*
- Alternative strategy one: **low intensity habits**
 - These work well when engaging in *learning is spontaneous, frustration level is low, and learning is automatically rewarding*
 - **Enjoyment** tends to come from being good at things. Once you feel competent in a skill, it starts to get a lot more fun
 - Therefore, he thinks pursuing aggressive ultralearning projects is often the surer way to *enjoy learning more* as you’re more likely to reach a level where learning automatically becomes fun
- Alternative strategy two: **formal, structured education**
 - The benefits of formal structured education is it allows you to interact with people in groups and with teachers or mentors

CHAPTER 14: AN UNCONVENTIONAL EDUCATION

- Psychologists recognize large difference between goals ***pursued intrinsically*** based on their own decisions, interests, and targets, and goals that they ***pursue extrinsically*** pushed by overbearing parents, punishing curricula, or demanding employers
 - The latter type, because the motivation for conforming to them comes primarily from *outside social pressures* are the cause of much misery

How to raise an Ultralearner

- [László Polgár](#), the man who raised his three daughters to be chess geniuses, outlined in his book how to turn any normal, healthy child into a genius
 - Book reference: [Bring Up Genius! \(Nevelj zsenit!\) by László Polgár](#)
- First step is to start early
 - Education should begin no later than three, and specialization to begin no later than six
 - There is evidence from other fields that children's brains are more plastic and flexible when younger
- The second step is to specialize
 - Even though the girls learned mathematics, language, sports, and other subjects, their focus was always in chess
 - Here they played 5 to 6 hours per day
 - By specializing in one subject, the children could reach proficiency at an early age
 - Winning against older and more experienced opponents in chess with build their self-confidence and competitive spirit so that they actively wanted to practice more to improve themselves
- The third step was to make practice into play
 - Keeping the game *fun and light* was a key steppingstone to developing a drive and self-confidence that would support more serious effort later
 - However, he insisted that "play is not the opposite of work, and a child does not need play separate from work, but meaningful action"
- Fourth, he was careful to create positive reinforcement, to make chess a pleasant rather than frustrating experience
 - Failure, suffering, and fearfulness decreased achievement
- Lastly, he was against coercive learning
 - *Self-discipline, motivation, and commitment* must come from the children themselves
 - One can never achieve serious pedagogical results especially at a high-level through coercion
 - ***One of the most important educational tasks is to teach self-education***
- In the beginning, you can start with projects that are more unique until your skill level and self confidence builds up
 - When your skill increases, you can challenge yourself and create a competitive environment
- In the workplace, make learning a priority and create a culture of learning

- **Learning** isn't about replacing ignorance with understanding. Ignorance expands with knowledge
 - ***Greater knowledge comes a greater appreciation for all the qualities that remain unanswered***
- Confidence must be paired with great humility

Full Book of ULTRALEARNING

Chapter 3- How Become UltraLearner.

"I'd love to be a guinea pig." It was an email from Tristan de Montebello. I had first met the charming, half-French, half-American musician and entrepreneur seven years earlier, at almost exactly the same time as my fateful encounter with Benny Lewis. With tousled blond hair and a closecropped beard, he looked like he belonged on a surfboard on some stretch of California coastline. De Montebello was the kind of guy you liked immediately: confident, yet down to earth, with only the vaguest hints of a French accent in his otherwise perfect English. Over the years, we had kept in touch: me with my strange learning experiments; him hopping around the world, going from working with a Parisian startup that made bespoke cashmere sweaters to guitarist, vagabond, and eventually web consultant in Los Angeles, much closer to the beaches that suited him so well. Now he had heard I was writing a book about learning, and he was interested.

The context of his email was that although I had met and documented dozens of people accomplishing strange and intriguing learning feats, the meetings had been largely after the fact. They were people I had met or heard about after their successes, not before; observations of successes, not experiments that generated them. As a result, it was hard to tell exactly how accessible this ultralearning thing was. If you filter through enough pebbles, you're sure to find a few flecks of gold. Was I doing the same thing, scouring for unusual learning projects? Sift through enough people, and you're bound to find some that seem incredible. But if ultralearning had the potential that I imagined it did, it would be nice to find someone before he or she tried a project and watch the results. To test this, I put together a small group of about a dozen people (mostly readers of my blog) who were interested in giving this ultralearning thing a shot. Among them was de Montebello.

Becoming an Ultralearner

"Maybe piano?" de Montebello suggested. Although he was interested in the concept of ultralearning, he had no idea which skill he'd like to learn. He had played guitar and been the lead singer for a band. With his musical background, learning to play piano seemed like a relatively safe choice. He had even made a course teaching guitar lessons online, so learning another musical instrument could potentially expand his business. Selfishly, I encouraged him to try learning something farther outside his comfort zone. A musician picking up another instrument didn't seem like the ideal case to study for seeing whether ultralearning could be applied broadly. We threw more ideas around. A week or two later, he decided on public speaking. His background as a musician had given him experience being onstage, but otherwise he had little experience giving speeches. Public speaking is a useful skill, too, he argued, so it would be worth getting better at even if nothing noteworthy came from the effort.

De Montebello had a private motivation for wanting to become good at public speaking. He had given only a handful of speeches in his life, and most of those had been in college. He related to me one example, from when he had gone to give a talk to a dozen people at a web design firm in Paris: "I cringe every time I think back to that." He explained, "I could just tell I wasn't connecting. There were many pieces where I was boring them. There

were jokes where I would laugh, because I thought it was funny, but nobody else would.” Being a musician, he was surprised “how little of it translated” to public speaking. Still, it was something in which he saw potential value, if he could get good at it. “Public speaking is a metaskill,” he feels. It’s the kind of skill that assists with other skills: “confidence, storytelling, writing, creativity, interviewing skills, selling skills. It touches on so many different things.” With that in mind, he set to work.

First Steps of a Fledgling Ultralearner

De Montebello had picked his topic, but he wasn’t sure exactly how he should learn it. He decided to attend a meeting of Toastmasters International, the organization for learning public speaking. At that point, his story had two doses of luck. The first was that in attendance at the very first meeting for his public speaking project was Michael Gendler. Gendler was a longtime Toastmaster, and de Montebello’s combination of charm and obsessive intensity to become good at public speaking convinced him to help coach de Montebello through his project. The second dose of luck was something that de Montebello didn’t fully appreciate at the time: he had showed up just ten days before the deadline to be eligible to compete in the World Championship of Public Speaking.

The World Championship of Public Speaking is a competition put on annually by Toastmasters in which members compete, elimination style, starting in individual clubs and going on to larger and larger units of the organization, until a select few make it to the final stage. De Montebello had little more than a week to prepare. Still, the competition provided a potential structure for his ultralearning project, so he went for it, cranking out the six mandatory qualifying speeches in the coming week, finishing the last in the nick of time.

De Montebello practiced obsessively, sometimes speaking twice in one day. He recorded a video of every speech and analyzed it obsessively for flaws. He asked for feedback every time he gave a speech, and he got plenty of it. His coach, Gendler, pushed him far outside of his comfort zone. Once, when faced with the choice between polishing an existing speech and creating a brand-new one from scratch, de Montebello asked what he should do. Gendler’s response was to do whichever was scariest for him.

His relentless drive pushed de Montebello into unusual places. He took improv classes to work on his spontaneous delivery. There he learned to trust whatever was in his head and deliver it without hesitation. That kept him from stammering over his words or fearing freezing up onstage. He talked to a friend who works as a Hollywood director to give feedback on his delivery. The director taught de Montebello to give his speech dozens of times in different styles—angry, monotone, screaming, even as a rap—then go back and see what was different from his normal voice. According to de Montebello, that helped break him of the “uncanny valley” that happened when his normal speaking delivery felt slightly unnatural.

Another friend with a background in theater gave him tips on stage presence. He took de Montebello through his speech and showed how each word and sentence indicated movement that could be translated to where he moved on the stage. Instead of standing constricted under the spotlight, de Montebello could now move gracefully and use his body to communicate his message on top of his words. He even gave his speech at a middle school, knowing that seventh graders would give the most ruthless feedback of all. After bombing terribly outside the comfort of Toastmasters, he learned to talk

to his audience before going onstage: learn their language and emotions and connect with them. That way, applying all he had learned so far, he could change his speech on the fly, so it would be sure to connect with a new audience. Above all, Gendler pushed him relentlessly. “Make me care,” Gendler told him after listening to one of de Montebello’s speeches. “I understand why this is important to you, but the audience doesn’t care about you. You have to make me care.” Diverse advice and voluminous practice would soak those lessons in deeply, allowing de Montebello to quickly surpass his early awkwardness on the stage.

After a month, de Montebello won his area competition, beating out a competitor with two decades of experience in Toastmasters. He won his district and division competitions, too. Finally, less than seven months after he first tried his hand at public speaking, he was going to compete in the World Championships. “There are about thirty thousand people who compete every year,” he noted, adding “I’m pretty confident I’m the fastest competitor in history to make it this far, since if I had started ten days later, I couldn’t have competed.” He made it into the top ten.

From Semifinalist to Career Change

“I knew this project was going to be big for me when I started it,” de Montebello told me months after his top ten placement in the international competition. “But it was literally life changing. I didn’t expect it to actually change my life.” Reaching the final competition in the World Championship had been quite a journey, but it was only afterward that he began to realize how much he had learned. “I was learning for this very narrow world of public speaking. It was only after that I realized the depth of all these skills I had worked so much on: storytelling, confidence, communicating.”

Friends who heard of de Montebello’s success started asking if he could help them work on their own speeches. He and Gendler saw an opportunity to help others improve their public speaking skills. The demand was intense. Authors who command five-figure speaking fees started to approach the duo to see if they could be taught to improve their public speaking the ultralearning way. Soon they had landed their first client, to the tune of twenty thousand dollars. Gendler and de Montebello weren’t mercenary; they wanted to focus only on speakers whose message they really believed in. But the fact that they had attracted such high-status clients certainly helped persuade them to make the switch into coaching public speaking full-time. Gendler and de Montebello even decided to name their consultancy UltraSpeaking, as a nod to the strategy that made it all possible.

De Montebello’s story ended up being much more dramatic than either of us had initially expected. His initial hope had been that he could practice intensely for a few months, deliver a great speech somewhere, and have it recorded—a nice memento and a new skill—but not that he would reach the status of an international competitor and eventually experience a complete career change. Of the other dozen or so people I spent some time coaching into ultralearning, none offered so dramatic an example. Some dropped out. Life got in the way (or perhaps revealed that they weren’t actually as committed as they had initially appeared to be). Others had respectable successes, making significant improvements in learning medicine, statistics, comic book drawing, military history, and yoga, even if they didn’t reach de Montebello’s degree of success.

What differentiated de Montebello wasn’t that he thought he could go from near-zero experience to the finalist for the World Championship in six

months. Rather, it was his obsessive work ethic. His goal wasn't to reach some predetermined extreme but to see how far he could go. Sometimes you'll get lucky and embark on a path that will take you quite far. But even the failure mode of ultralearning is usually that you will learn a skill fairly well. Even those who didn't have such dramatic results among the small group I spent time coaching, those who stuck with their project still ended up learning a new skill they cared about. You may not compete in world championships or completely switch careers, but as long as you stick with the process, you're bound to learn something new. What de Montebello's example encapsulated for me was not only that you can become an ultralearner but that such successes are far from being the inevitable consequences of having a particular kind of genius or talent. Had de Montebello focused on piano instead, his experience with giving speeches would probably have remained that one awkward example from his days in Paris.

Principles of Becoming an Ultralearner

De Montebello's story illustrates that it's possible to decide to become an ultralearner. But ultralearning isn't a cookie-cutter method. Every project is unique, and so are the methods needed to master it. The uniqueness of ultralearning projects is one of the elements that ties them all together. If ultralearning could be bottled or standardized, it would simply be an intense form of structured education. What makes ultralearning interesting is also what makes it hard to boil down into step-by-step formulas.

This is a difficult challenge, but I'm going to try to sidestep it by focusing on principles first. Principles allow you to solve problems, even those you may have never encountered before, in a way that a recipe or mechanical procedure cannot. If you really understand the principles of physics, for instance, you can solve a new problem simply by working backward.

Principles make sense of the world, and even if they don't always articulate exactly how you should solve a particular challenge, they can provide immense guidance. Ultralearning, in my view, works best when you see it through a simple set of principles, rather than trying to copy and paste exact steps or protocols.

The principles of ultralearning are going to be the focus of the second part of this book. In each chapter, I'll introduce a new principle, plus some evidence to back it up both from ultralearning examples and from scientific research. Finally, I'll share possible ways that the principle can manifest itself as specific tactics. These tactics are only a small sample. But they should provide a starting point for you to think creatively about your own ultralearning challenges.

There are nine universal principles that underlie the ultralearning projects described so far. Each embodies a particular aspect of successful learning, and I describe how ultralearners maximize the effectiveness of the principle through the choices they make in their projects. They are:

1. **METALEARNING: FIRST DRAW A MAP.** Start by learning how to learn the subject or skill you want to tackle. Discover how to do good research and how to draw on your past competencies to learn new skills more easily.
2. **FOCUS: SHARPEN YOUR KNIFE.** Cultivate the ability to concentrate. Carve out chunks of time when you can focus on learning, and make it easy to just do it.
3. **DIRECTNESS: GO STRAIGHT AHEAD.** Learn by doing the thing you want to

become good at. Don't trade it off for other tasks, just because those are more convenient or comfortable.

4. DRILL: ATTACK YOUR WEAKEST POINT. Be ruthless in improving your weakest points. Break down complex skills into small parts; then master those parts and build them back together again.

5. RETRIEVAL: TEST TO LEARN. Testing isn't simply a way of assessing knowledge but a way of creating it. Test yourself before you feel confident, and push yourself to actively recall information rather than passively review it.

6. FEEDBACK: DON'T DODGE THE PUNCHES. Feedback is harsh and uncomfortable. Know how to use it without letting your ego get in the way. Extract the signal from the noise, so you know what to pay attention to and what to ignore.

7. RETENTION: DON'T FILL A LEAKY BUCKET. Understand what you forget and why. Learn to remember things not just for now but forever.

8. INTUITION: DIG DEEP BEFORE BUILDING UP. Develop your intuition through play and exploration of concepts and skills. Understand how understanding works, and don't recourse to cheap tricks of memorization to avoid deeply knowing things.

9. EXPERIMENTATION: EXPLORE OUTSIDE YOUR COMFORT ZONE. All of these principles are only starting points. True mastery comes not just from following the path trodden by others but from exploring possibilities they haven't yet imagined.

I organized these nine principles based on my observations of ultralearning projects as well as my own personal experience, referencing, where I could, the vast cognitive science literature. I started with the ultralearners themselves. If one person did something in a certain way, that might be an interesting example, but it might also be an idiosyncrasy of that person. If several people or, better yet, every ultralearner I encountered, did a certain thing in a certain way, it was much stronger evidence that I had stumbled upon a general principle. I then checked those principles against the scientific literature. Are there mechanisms and findings from cognitive science to support the tactics I saw? Better yet, have there been controlled experiments comparing one approach to learning with another? The scientific research supports many of the learning strategies employed by the ultralearners I witnessed. This suggests that ultralearners, with their ruthless focus on efficiency and effectiveness, may have landed on some universal principles in the art of learning.

Beyond principles and tactics is a broader ultralearning ethos. It's one of taking responsibility for your own learning: deciding what you want to learn, how you want to learn it, and crafting your own plan to learn what you need to. You're the one in charge, and you're the one who's ultimately responsible for the results you generate. If you approach ultralearning in that spirit, you should take these principles as flexible guidelines, not as rigid rules. Learning well isn't just about following a set of prescriptions. You need to try things out for yourself, think hard about the nature of the learning challenges you face, and test solutions to overcome them. With that in mind, let's turn to the first ultralearning principle: metalearning.

Chapter 4- Principle 1- Metalearning: First Draw A Map

Dan Everett stands in front of a packed auditorium. A stocky man in his early sixties, he speaks slowly and confidently, his smiling face framed by thinning blond hair and a beard. Next to him is a table filled with assorted objects: sticks, stones, leaves, containers, fruit, a pitcher of water. He signals that the demonstration is about to begin.

Entering from a door on the right, a heavyset middle-aged woman with dark brown hair and olive skin approaches the stage. Everett goes up to her and says something in a language she doesn't understand. She looks around, clearly confused, and then replies hesitantly, "Kuti paoka djalou."¹ He tries to repeat what she has just said. There's some stumbling at first, but after one or two more tries, she seems satisfied with his repetition of her reply. He goes to the blackboard and writes, "Kuti paoka djalou ⇒ 'Greeting (?)'." Next he picks up a small stick and points to it. She guesses correctly that he wants to know the name and replies, "ηkindo." Once again, Everett goes to the blackboard and writes, "ηkindo ⇒ stick." Next he tries two sticks and gets the same response, "ηkindo." He then drops the stick, to which the woman says, "ηkindo paula." The demonstration proceeds, with Everett picking up objects, performing actions, listening to the woman's responses, and recording the results on the blackboard. Soon he's moved past simple naming tasks and starts asking for more complicated sentences: "She drinks the water," "You eat the banana," and "Put the rock in the container." With each new elicitation, he experiments, building new sentences and testing her reaction to see if he is correct. Within half an hour, there are more than two blackboards full of nouns, verbs, pronouns, and phonetic annotations. Learning dozens of words and phrases in a new language is a good start for the first thirty minutes spent with any language. What makes this feat particularly impressive is that Everett isn't allowed to speak any language he might have in common with the speaker.² He can only try to encourage her to say words and phrases and repeat them to try to figure out the language's grammar, pronunciation, and vocabulary. He doesn't even know what language is being spoken.*

How can Everett start speaking a new language from scratch, without teachers or translations or even knowing what language he's learning, in half an hour, when most of us struggle to do the same after years of high school Spanish classes? What enables Everett to pick up vocabulary, decode grammar, and pronunciation so much faster than you or I, even with all those additional constraints? Is he a linguistic genius, or is there something else going on?

The answer is our first principle of ultralearning: metalearning.

What Is Metalearning?

The prefix meta comes from the Greek term μετά, meaning "beyond." It typically signifies when something is "about" itself or deals with a higher layer of abstraction. In this case metalearning means learning about learning. Here's an example: If you're learning Chinese characters, you will learn that 火 means "fire." That's regular learning. You may also learn that Chinese characters are often organized by something called radicals, which indicate what kind of thing the character describes. The character 灶, for example which means "stove," has a 火 on the left-hand side to indicate that it has some relationship to fire. Learning this property of Chinese characters is

metalearning—not learning about the object of your inquiry itself, in this case words and phrases, but learning about how knowledge is structured and acquired within this subject; in other words, learning how to learn it.

In Everett's case, we can see glimpses of the enormous wealth of metalearning that lies just beneath the surface. "Well, what are some of the things we noticed about this?" Everett asks the audience after his brief demonstration has concluded, "It seems to be SVO, a subject-verb-object language, that's not terribly shocking." He continues, "There doesn't seem to be any plural marking on the nouns, unless it's tones and I missed it. . . .

There's clearly pitch going on here; whether it's tone remains to be analyzed." From this jargon we can see that when Everett evokes a word or phrase from his interlocutor, he isn't just parroting back the sounds; he's drawing a map with theories and hypotheses about how the language works grounded on years of experience learning languages.

In addition to his enormous wealth of knowledge as a linguist, Everett has another trick that gives him an enormous advantage. The demonstration he has presented is not his own invention. Called a "monolingual fieldwork" demonstration, this method was first developed by Everett's teacher Kenneth Pike as a means of learning indigenous languages. The method lays out a sequence of objects and actions that the practitioner can use to start piecing together the language. This method even received some Hollywood exposure after Louise Banks, a fictional linguist, used it to decode an alien language in the 2016 science fiction movie *Arrival*.

These two pieces in Everett's linguistic arsenal—a richly detailed map of how languages work and a method that provides a path to fluency—have allowed Everett to accomplish a lot more than just learning some simple sentences. Over the last thirty years he has become one of only a handful of outsiders to become fluent in Pirahã, one of the most unusual and difficult languages on the planet, spoken only by a remote tribe in the Amazon jungle.³

The Power of Your Metalearning Map

Everett's case beautifully illustrates the power of using metalearning to learn new things faster and more effectively. Being able to see how a subject works, what kinds of skills and information must be mastered, and what methods are available to do so more effectively is at the heart of success of all ultralearning projects. Metalearning thus forms the map, showing you how to get to your destination without getting lost.

To see why metalearning is so important, consider one study on the helpful effects of already knowing a second language when learning a third.⁴ The study took place in Texas, where monolingual English speakers and bilingual Spanish/English speakers were enrolled in a French class. Follow-up on subsequent tests showed that the bilingual speakers outperformed the monolingual students when learning a new language. On its own, this isn't terribly surprising. French and Spanish are both Romance languages, so there are shared features of grammar and vocabulary that aren't present in English that could conceivably provide an advantage. More interesting, however, is that even among the Spanish/English bilinguals, those who also took Spanish classes ended up doing better when they later needed to learn French. The reason seems to be that taking classes assists with helping form what the study authors call metalinguistic awareness in a way that simply knowing a language informally does not. The difference between the two types of bilingual speakers mostly came down to metalearning: one group had content

knowledge of the language, but the group that took classes also had knowledge about how information in a language is structured.*

Nor is this idea about metalearning restricted to languages. Linguistic examples are often easier to study because there's a cleaner separation of metalearning and regular learning. This is because the contents of unrelated languages, such as vocabulary and grammar, are often quite different, even if the metalearning structure is the same. Learning French vocabulary won't help you much with learning Chinese vocabulary, but understanding how vocabulary acquisition works in French will likely also help with learning Chinese. By the time my friend and I had reached the last country in our year of learning languages, the process of immersing ourselves and learning a new language from scratch was practically a routine. The words and grammar of Korean may have been completely new, but the process of learning was already well trodden. Metalearning exists in all subjects, but it can often be harder to examine independently from regular learning.

How to Draw Your Map

Now that you have some idea what metalearning is and its importance to learning faster, how can you apply this to get an edge in your own learning efforts? There are two main ways: over the short term and over the long term. Over the short term, you can do research to focus on improving your metalearning before and during a learning project. Ultralearning, owing to its intensity and self-directed nature, has the opportunity for a lot higher variance than normal schooling efforts do. A good ultralearning project, with excellent materials and an awareness of what needs to be learned, has the potential to be completed faster than formal schooling. Language learning through intensive immersion can beat lengthy classes. Aggressively paced coding bootcamps can get participants up to a level where they can compete for jobs much faster than those with a normal undergraduate degree. This is because you can tailor your project to your exact needs and abilities, avoiding the one-size-fits-all approach taken in school. However, there's also a danger of choosing unwisely and ending up much worse off. Metalearning research avoids this problem and helps you seek out points where you might even be able to get a significant advantage over the status quo.

Over the long term, the more ultralearning projects you do, the larger your set of general metalearning skills will be. You'll know what your capacity is for learning, how you can best schedule your time and manage your motivation, and you'll have well-tested strategies for dealing with common problems. As you learn more things, you'll acquire more and more confidence, which will allow you to enjoy the process of learning more with less frustration.

In this chapter, I'm going to devote most of the next section to short-term research strategies, since they will probably benefit you the most. However, this emphasis shouldn't undermine the importance of the long-term effects of metalearning. Ultralearning is a skill, just like riding a bicycle. The more practice you get with it, the more skills and knowledge you'll pick up for how to do it well. This long-term advantage likely outweighs the short-term benefits and is what's easiest to mistake for intelligence or talent when seen in others. My hope is that as you get more practice in ultralearning, you'll start to automatically apply many of those skills to learn faster and more effectively.

Determining Why, What, and How

I find it useful to break down metalearning research that you do for a specific

project into three questions: “Why?,” “What?,” and “How?” “Why?” refers to understanding your motivation to learn. If you know exactly why you want to learn a skill or subject, you can save a lot of time by focusing your project on exactly what matters most to you. “What?” refers to the knowledge and abilities you’ll need to acquire in order to be successful. Breaking things down into concepts, facts, and procedures can enable you to map out what obstacles you’ll face and how best to overcome them. “How?” refers to the resources, environment, and methods you’ll use when learning. Making careful choices here can make a big difference in your overall effectiveness. With these three questions in mind, let’s take a look at each of them and how you can draw your map.

Answering “Why?”

The first question to try to answer is why are you learning and what that implies for how you should approach the project. Practically speaking, the projects you take on are going to have one of two broad motivations: instrumental and intrinsic.

Instrumental learning projects are those you’re learning with the purpose of achieving a different, nonlearning result. Consider the previously mentioned case of Diana Fehsenfeld, who, after a few decades as a librarian, found that her job was becoming obsolete. Computerized file systems and budget cuts meant she would need to learn new skills to stay relevant. She did some research and decided that the best way to do this would be to get a firmer grasp on statistics and data visualization. In this case, she wasn’t learning because of her deep love of statistics and data visualization but because she believed that doing so would benefit her career.

Intrinsic projects are those that you’re pursuing for their own sake. If you’ve always wanted to speak French, even though you’re not sure how you’ll use it yet, that’s an intrinsic project. Intrinsic doesn’t mean useless. Learning French might have benefits later when you decide to travel or need to work with a client from France at your job. The difference is that you’re learning the subject for its own sake, not as a means to some other outcome. If you’re pursuing a project for mostly instrumental reasons, it’s often a good idea to do an additional step of research: determining whether learning the skill or topic in question will actually help you achieve your goal. I’ve often heard stories of people unhappy with their career progress who decide that attending graduate school is the answer. If only they had an MBA or an MA, employers would take them more seriously, they think, and they’d have the career they desire. So they go off to school for two years, rack up tens of thousands of dollars in student debt, and discover that their newly minted credentials don’t actually get them much better job opportunities than before. The fix here is to do your research first. Determine if learning a topic is likely to have the effect you want it to before you get started.⁵

Tactic: The Expert Interview Method

The main way you can do research of this kind is to talk to people who have already achieved what you want to achieve. Let’s say you want to become a successful architect and think that mastering design skills might be the best step to take. Before you get started, it would be a good idea to talk to some successful architects to get a sense of whether they think your project will actually help with your intended goal. Though this method can be used for many parts of the research process, I’ve found it particularly valuable for vetting instrumental projects. If someone who has already accomplished the goal you want to achieve doesn’t think your learning project will help reach it

or thinks it's less important than mastering some other skill, that's a good sign that your motivation and the project are misaligned.

Finding such people isn't as hard as it sounds. If your goal is career related, look for people who have the career you want and send them an email. You can find them at your current workplace, conferences, or seminars, or even on social networking websites such as Twitter or LinkedIn. If your goal is related to something else, you can search online in forums dedicated to the subject you want to learn. If you want to learn programming, with the goal of building your own apps, for example, you can find online forums dedicated to programming or app development. Then you just need to look for frequent posters who seem to have the knowledge you're looking for and email them.

Reaching out and setting up a meeting with an expert isn't hard, either, but it's a step many people shy away from. Many people, particularly the introverts among us, recoil at the idea of reaching out to a stranger to ask for advice. They worry that they'll be rejected, ignored, or even yelled at for presuming to take up a person's time. The truth is, however, that this rarely happens. Most experts are more than willing to offer advice and are flattered by the thought that someone wants to learn from their experience. The key is to write a simple, to-the-point email, explaining why you're reaching out to them and asking if they could spare fifteen minutes to answer some simple questions. Make the email concise and nonthreatening. Don't ask for more than fifteen minutes or for ongoing mentorship. Though some experts will be happy to help you in those ways, it's not good form to ask for too much in the first email.

What if the person you want to interview doesn't live in your city? In that case, phone or online calls are great alternatives.* Email can work in a pinch, too, but I've found that text often doesn't translate tone well, and you often miss sensing the way the person feels about your project. Saying it's a "great idea" lukewarmly versus enthusiastically can make a world of difference, yet that nuance is missing if you communicate via text only.

Even if your project is intrinsically motivated, asking "Why?" is still very useful. Most learning plans you might choose to emulate will be based on curriculum designers' ideas of what is important for you to learn. If these aren't perfectly lined up with your own goals, you may end up spending a lot of time learning things that aren't important to you or underemphasizing the things that do matter. For these kinds of projects, it's useful to ask yourself what you're trying to learn because it will help you evaluate different study plans for their fit with your goals.

Answering "What?"

Once you've gotten a handle on why you're learning, you can start looking at how the knowledge in your subject is structured. A good way to do this is to write down on a sheet of paper three columns with the headings "Concepts," "Facts," and "Procedures." Then brainstorm all the things you'll need to learn. It doesn't matter if the list is perfectly complete or accurate at this stage. You can always revise it later. Your goal here is to get a rough first pass. Once you start learning, you can adjust the list if you discover that your categories aren't quite right.

Concepts

In the first column, write down anything that needs to be understood.

Concepts are ideas that you need to understand in flexible ways in order for them to be useful. Math and physics, for example, are both subjects that lean

heavily toward concepts. Some subjects straddle the concept/fact divide, such as law, which has legal principles that need to be understood, as well as details that need to be memorized. In general, if something needs to be understood, not just memorized, I put it into this column instead of the second column for facts.

Facts

In the second column, write down anything that needs to be memorized.

Facts are anything that suffices if you can remember them at all. You don't need to understand them too deeply, so long as you can recall them in the right situations. Languages, for instance, are full of facts about vocabulary, pronunciation, and, to a lesser extent, grammar. Even concept-heavy subjects usually have some facts. If you're learning calculus, you will need to deeply understand how derivatives work, but it may be sufficient to memorize some trigonometric identities.

Procedures

In the third column, write down anything that needs to be practiced.

Procedures are actions that need to be performed and may not involve much conscious thinking at all. Learning to ride a bicycle, for instance, is almost all procedural and involves essentially no facts or concepts. Many other skills are mostly procedural, while others may have a procedural component yet still have facts to memorize and concepts to understand. Learning new vocabulary in a language requires memorizing facts, but pronunciation requires practice and therefore belongs in this column.

Using This Analysis to Draw Your Map

Once you've finished your brainstorm, underline the concepts, facts, and procedures that are going to be most challenging. This will give you a good idea what the major learning bottlenecks are going to be and can start you searching for methods and resources to overcome those difficulties. You might recognize that learning medicine requires a lot of memorization, so you may invest in a system such as spaced-repetition software. If you're learning mathematics, you might recognize that deep understanding of certain concepts is going to be the tricky spot and consider spending time explaining those concepts to other people so you really understand them yourself. Knowing what the bottlenecks will be can help you start to think of ways of making your study time more efficient and effective, as well as avoid tools that probably won't be too helpful to your goal.

Often this coarse-grained analysis is enough to move on to the next phase of research. However, with more experience, you can dig deeper. You might look at some of the particular features of the concepts, facts, and procedures you're trying to learn to find methods to master them more effectively. When I started my portrait-drawing challenge, for instance, I knew that success would depend highly on how accurately I could size and place facial features. Most people can't draw realistic faces because if those attributes are off even slightly (such as making a face too wide or the eyes too high), they will instantly look wrong to our sophisticated ability to recognize faces.

Therefore, I got the idea of doing lots and lots of sketches and comparing them by overlaying the reference photos. That way I could quickly diagnose what kinds of errors I was making without having to guess. If you can't make these kinds of predictions and come up with these kinds of strategies just yet, don't worry. This is the kind of long-term benefit of metalearning that comes from having done more projects.

Answering "How?"

Now that you've answered two questions—why you're learning and what you're learning—it's time to answer the final question: How are you going to learn it?

I suggest following two methods to answer how you'll learn something: Benchmarking and the Emphasize/Exclude Method.

Benchmarking

The way to start any learning project is by finding the common ways in which people learn the skill or subject. This can help you design a default strategy as a starting point.

If I'm trying to learn something that is taught in school, say computer science, neurology, or history, one thing I'll do is look at the curricula used in schools to teach that subject. This could be the syllabus from a single class or, as in the case of my MIT Challenge, the course list for an entire degree. When I wanted to learn more about cognitive science, I found a list of textbooks that the University of San Diego's Cognitive Science doctoral program recommends for incoming students without cognitive science backgrounds. Good resources to consider for this approach are universities (MIT, Harvard, Yale, and Stanford are good examples but far from the only ones). Generally course lists and syllabi are available by looking on their websites aimed at existing students.

If I'm trying to learn a nonacademic subject or a professional skill, I'll probably instead do online searches for people who have previously learned that skill or use the Expert Interview Method to focus on resources available for mastering that subject. An hour spent searching online for almost any skill should turn up courses, articles, and recommendations for how to learn it. Investing the time here can have incredible benefits because the quality of the materials you use can create orders-of-magnitude differences in your effectiveness. Even if you're eager to start learning right away, investing a few hours now can save you dozens or hundreds later on.

The Emphasize/Exclude Method

Once you've found a default curriculum, you can consider making modifications to it. I find this easier to do with skills that have obvious success criteria (say drawing, languages, or music) and for which you can generally make a guess at the relative importance to the subject topics prior to studying them. For conceptual subjects or topics where you may not even understand the meaning of the terms in the syllabus, it's probably better to stick closer to your benchmark until you learn a bit more.

The Emphasize/Exclude Method involves first finding areas of study that align with the goals you identified in the first part of your research. If you're learning French with the idea of going to Paris for two weeks and speaking in shops and restaurants, I would focus a lot more on pronunciation than being able to spell correctly. If you're learning programming solely to make your own app, I'd focus on the inner workings of app development more than theories of computation.

The second part of the Emphasize/Exclude Method is to omit or delay elements of your benchmarked curriculum that don't align with your goals. For example, one common recommendation for learning Mandarin Chinese, advocated by people such as the renowned linguist and Sinologist Victor Mair, is to focus on learning to speak before you try to read characters.⁶ This isn't the only route available, but if your main goal is to speak, then this path to fluency might be more effective.

How Much Planning Should You Do?

One question you may face is when to stop doing research and just get started. The literature on self-directed learning, as typically practiced, demonstrates that most people fail to do a thorough investigation of possible learning goals, methods, and resources.⁷ Instead they opt for whatever method of learning comes up naturally in their environment. This clearly leaves a gap between what is practiced and the efficiency that is possible using the best possible method. However, research can also be a way of procrastinating, particularly if the method of learning is uncomfortable. Just doing a bit more research then becomes a strategy to avoid doing the work of learning. There will always be some uncertainty in your approach, so it's important to find the sweet spot between insufficient research and analysis paralysis. You know when you're procrastinating, so just get started.

The 10 Percent Rule

A good rule of thumb is that you should invest approximately 10 percent of your total expected learning time into research prior to starting. If you expect to spend six months learning, roughly four hours per week, that would be equal to roughly one hundred hours, which suggests that you should spend about ten hours, or two weeks, doing your research. This percentage will decrease a little bit as your project scales up, so if you plan to do five hundred or a thousand hours of learning, I don't think it necessarily demands fifty or a hundred hours of research, but maybe closer to 5 percent of your time. The goal here isn't to exhaust every learning possibility but simply to make sure you haven't latched onto the first possible resource or method without thinking through alternatives. Prior to starting my MIT Challenge, I spent roughly six months, part-time, combing through all the course materials. A good idea is to be aware of the common methods of learning, popular resources, and tools along with their strengths and weaknesses before starting. Long projects provide more opportunities for getting derailed and delayed, so doing proper research in the beginning can easily save a much larger amount of time later on.

Diminishing Returns and Marginal Benefit Calculation

Metalearning research isn't a onetime activity you do only before starting your project. You should continue to do research as you learn more. Often obstacles and opportunities aren't clear before you start, so reassessing is a necessary step of the learning process. During my portrait-drawing challenge, for instance, I discovered about halfway that I was getting diminishing returns from my sketch-and-compare method. I realized that I needed a better technique for drawing that had higher accuracy. That led me to do a second round of research, leading to a course taught by Vitruvian Studio, which detailed a more systematic method that greatly increased my accuracy.⁸ I hadn't noticed it in my original research because I wasn't aware of the deficiency of my self-developed technique.

A more sophisticated answer to the question of when and how to do research would be to compare the marginal benefits of metalearning to regular learning. One way to do this is to spend a few hours doing more research—interviewing more experts, searching online for more resources, searching for new possible techniques—and then spend a few hours doing more learning along your chosen path. After spending some time on each, do a quick assessment of the relative value of the two activities. If you feel as though the metalearning research contributed more than the hours spent on learning itself, you are likely at a point where more research is still beneficial. If you felt that the extra research wasn't too helpful, you're probably better

off sticking to the plan you had before. This type of analysis depends on something known as the Law of Diminishing Returns. This states that the more time you invest in an activity (such as more research), the weaker and weaker the benefits will be as you get closer and closer to the ideal approach. If you keep doing research, eventually it will be less valuable than simply doing more learning, so at that point you can safely focus on learning. In practice, the return to research tends to be lumpy and variable. You might spend a few hours and get nothing, then stumble onto the perfect resource for accelerating your progress. As you finish more projects, it's easier to judge this point intuitively, but the Law of Diminishing Returns and the 10 Percent Rule can provide good approximations for how much research to do and when.

Long-Term Prospects for Metalearning

So far we've talked only about the short-term benefits. However, the real benefits of metalearning aren't short term but long term. They don't reside in a particular project but influence your overall strengths as a learner.

Each project you do will improve your general metalearning. Every project has the opportunity to teach you new learning methods, new ways to gather resources, better time management, and improved skills for managing your motivation. Success in one project will give you confidence to execute your next one with boldness and without self-doubt and procrastination.

Ultimately, this effect far outweighs the effect of doing a specific project.

Unfortunately, it's also something that can't be boiled down to a tactic or tool. Long-term metalearning is just something you acquire with experience.

The benefits of ultralearning aren't always apparent from the first project because that first project occurs when you're at your lowest level of metalearning ability. Each project you complete will give you new tools to tackle the next, starting a virtuous cycle. Many of the ultralearners I interviewed for this book told me a similar story: that they were proud of their accomplishments in individual projects but that the real benefit had been that they now understood the process of learning hard things. That gave them the confidence to pursue other ambitious goals that they wouldn't have even considered previously. This confidence and ability are the ultimate goals of ultralearning, even though they're often hard to see from the outset. These benefits, however, can be achieved only by putting in the work. The best research, resources, and strategies are useless unless you follow up with concentrated efforts to learn. That brings us to the next principle of ultralearning: focus.

Chapter 5- Principle 2- Focus: Sharpen Your Knife.

If ever there were an unlikely candidate for scientific greatness, it would have been Mary Somerville. She was born into a poor Scottish family in the eighteenth century, when higher education was not seen as proper for a lady. Her mother did not prevent her from reading, but society at large did not approve of it. An aunt, seeing that behavior, commented to her mother, “I wonder you let Mary waste her time in reading, she never sews more than if she were a man.” When she did have an opportunity to attend school briefly, her mother regretted the expense. Somerville explained, “she would have been contented if I had only learnt to write well and keep accounts, which was all that a woman was expected to know.”¹ As a woman, she faced even larger obstacles, with household duties and expectations taking precedence over any kind of self-education. “A man can always command his time under the plea of business, a woman is not allowed any such excuse,” she lamented. Her first husband, Samuel Greig, was strongly against learning in women. Yet despite those obstacles, Somerville’s accomplishments were vast. She won awards in mathematics, learned several languages to fluency, and knew how to paint and play the piano. In 1835, she, along with the German astronomer Caroline Herschel, were the first women elected to the Royal Astronomical Society. The accomplishment that eventually brought her fame was her translation and expansion of the first two volumes of Pierre-Simon Laplace’s *Traité de mécanique céleste*, a massive five-volume work on the theory of gravitation and advanced mathematics, acclaimed as the greatest intellectual achievement since Isaac Newton wrote the *Principia Mathematica*. Laplace himself commented that Somerville was the only woman in the world who understood his work.

The easiest explanation for the vast discrepancy in Somerville’s situation and her accomplishments would be genius. It is no doubt true that she possessed an incredibly sharp mind. Her daughter once commented that while she was being taught, her mother could grow impatient. “I well remember her slender white hand pointing impatiently to the book or slate—‘Don’t you see it? There is no difficulty in it, it is quite clear.’” However, in reading through her descriptions of her life, this seeming genius was beset by many insecurities. She claimed to have “bad memory,” recounted struggles learning new things as a child, and had even at one point “thought [herself] too old to learn to speak a foreign language.” Whether that was polite modesty or genuine feelings of inadequacy, we cannot know, but it does at least put cracks in the idea that she approached learning from a place of unshakable confidence and talent.

Peering deeper, another picture of Somerville emerges. She had a keen intellect, yes, but what she possessed in even greater quantities was an exceptional ability to focus. As an adolescent, when she was put to bed and denied a candle for reading, she would mentally work through the works of Euclid in mathematics. While still breastfeeding her child, an acquaintance encouraged her to study botany, so she devoted “an hour of study to that science” every morning. Even during her greatest achievement, the translation and expansion of Laplace’s *Traité de mécanique céleste*, she had to carry out all the household duties of raising children, cooking, and cleaning. “I was always supposed to be at home,” she explains, “and my friends and acquaintances came so far out of their way on purpose to see me, it would have been unkind and ungenerous not to receive them. Nevertheless,

I was sometimes annoyed when in the midst of a difficult problem one would enter and say, 'I have come to spend a few hours with you.' However, I learnt by habit to leave a subject and resume it again at once, like putting a mark into a book I might be reading."

In the realm of great intellectual accomplishments an ability to focus quickly and deeply is nearly ubiquitous. Albert Einstein focused so intensely during his formulation of the general theory of relativity that he developed stomach problems. The mathematician Paul Erdős was a heavy user of amphetamines to increase his capacity for focus. When a friend bet him that he could not give them up, even for a short time, he did manage to do so. Later, however, he complained that the only result had been that mathematics as a whole was set back a month in his unfocused absence. In these annals of extreme focus, one often conjures up an image of solitary geniuses laboring away without distraction, free from worldly concerns. However remarkable this is, I'm more interested in the kind of focus that Somerville seemed to possess. How can one in an environment such as hers, with constant distractions, little social support, and continuous obligations, manage to focus long enough not only to learn an impressive breadth of subjects, but to such depths that the French mathematician Simon-Denis Poisson once remarked that "there were not twenty men in France who could read [her] book"?

How did Somerville become so good at focusing? What can we glean from her strategies in getting difficult mental work done in less-than-ideal conditions? The struggles with focus that people have generally come in three broad varieties: starting, sustaining, and optimizing the quality of one's focus. Ultralearners are relentless in coming up with solutions to handle these three problems, which form the basis of an ability to focus well and learn deeply.

Problem 1: Failing to Start Focusing (aka Procrastinating)

The first problem that many people have is starting to focus. The most obvious way this manifests itself is when you procrastinate: instead of doing the thing you're supposed to, you work on something else or slack off. For some people, procrastination is the constant state of their lives, running away from one task to another until deadlines force them to focus and then having to struggle to get the job done on time. Other people struggle with more acute forms of procrastination that manifest themselves with particular kinds of tasks. I was more like this second kind of person, where there were certain types of activities I would spend all day procrastinating on. Though I have no problems writing essays for my blog, when I had to do research for this book, I dragged my feet. Similarly, I had no problem sitting and watching the videos of MIT classes, but I always tackled the first problem sets with considerable trepidation. Had it not been for the intense schedule I was on, I might have found excuses to avoid doing so for much longer. In fact, writing this chapter was one of the tasks I procrastinated on a great deal.

Why do we procrastinate? The simple answer is that at some level there's a craving that drives you to do something else, there's an aversion to doing the task itself, or both. In my case, I procrastinated on writing this chapter because I had a lot of ideas and I was unsure where to start. My anxiety was that by committing something to paper, there was a good chance I might end up writing it poorly. Silly, I know. But most motives to procrastinate are silly when you verbalize them, yet that doesn't stop them from ruling your life. Which brings me to the first step to overcoming procrastination: recognize when you are procrastinating.

Much procrastination is unconscious. You're procrastinating, but you don't internalize it that way. Instead you're "taking a much-needed break" or "having fun, because life can't always be about work all the time." The problem isn't those beliefs. The problem is when they're used to cover up the actual behavior—you don't want to do the thing you need to be focusing on, either because you are directly averse to doing it or because there's something else you want to do more. Recognizing that you're procrastinating is the first step to avoiding it.

Make a mental habit of every time you procrastinate; try to recognize that you are feeling some desire not to do that task or a stronger desire to do something else. You might even want to ask yourself which feeling is more powerful in that moment—is the problem more that you have a strong urge to do a different activity (e.g., eat something, check your phone, take a nap) or that you have a strong urge to avoid the thing you should be doing because you imagine it will be uncomfortable, painful, or frustrating? This awareness is necessary for progress to be made, so if you feel as though procrastination is a weakness of yours, make building this awareness your first priority before you try to fix the problem.

Once you can easily and automatically recognize your tendency to procrastinate, when it occurs, you can take steps to resist the impulse. One way is to think in terms of a series of "crutches" or mental tools that can help you get through some of the worst parts of your tendency to procrastinate. As you get better about taking action on the project you're working on, these crutches can be changed or gotten rid of altogether when procrastination is no longer a problem.

A first crutch comes from recognizing that most of what is unpleasant in a task (if you are averse to it) or what is pleasant about an alternative task (if you're drawn to distraction) is an impulse that doesn't actually last that long. If you actually start working or ignore a potent distractor, it usually only takes a couple minutes until the worry starts to dissolve, even for fairly unpleasant tasks. Therefore, a good first crutch is to convince yourself to get over just the few minutes of maximal unpleasantness before you take a break. Telling yourself that you need to spend only five minutes on the task before you can stop and do something else is often enough to get you started. After all, almost anyone can endure five minutes of anything, no matter how boring, frustrating, or difficult it may be. However, once you start, you may end up continuing for longer without wanting to take the break.

As you progress, your first crutch may start to get in the way. You may find yourself starting but then, because the task is unpleasant and focus is hard, taking advantage of the five-minute rule too often to be productive. If this is the case and your problem has switched from being unable to get started to taking breaks too often, you can try something a little harder, say the Pomodoro Technique: twenty-five minutes of focus followed by a five-minute break.* Keep in mind that it's essential not to switch to a harder goal when you're still mostly impeded by an earlier problem. If you still can't start working, even with the five-minute rule, switching to harder and more demanding crutches may backfire.

In some cases, the moment of frustration may not come at the beginning, but still be predictable. When I was learning Chinese characters through flash cards, for instance, I'd always feel an urge to give up whenever I couldn't remember the answer to one of my cards. I knew this feeling was temporary, however, so I added a rule for myself: I can only quit when I've remembered

the most recent card correctly. In practice, the cards were quick, so this usually only took an extra twenty or thirty seconds of persistence; however, my patience for doing flash cards went up dramatically as a result.

Eventually, if working on your project is not troubled by extreme procrastination, you may want to switch to using a calendar on which you carve out specific hours of your day in advance to work on the project. This approach allows you to make the best use of your limited time. However, it works only if you actually follow it. If you find yourself setting a daily schedule with chunked hours and then frequently ignore it to do something else, go back to the start and try building back up again with the five-minute rule and then the Pomodoro Technique.

Eventually, you may reach Mary Somerville's level of focus, one that she could activate on a moment-to-moment basis, making a decision as to whether she had time to spare. Despite her formidable capacity for focus, it seems that even Somerville would deliberately block out time for the study of particular subjects. Therefore it was a conscious habit, not merely spontaneous studying, that enabled her many successes. For myself, I find that some learning activities are so intrinsically interesting that I can focus on them for a long time without pressure. I generally had no problem watching lectures during the MIT Challenge, for instance. Other tasks, however, required the five-minute rule for me to get past my desire to procrastinate. If I had to scan and upload my files, they'd often build up in a pile before I would finally tackle them. Don't ever feel bad if you have to back up a stage, either; you cannot control your aversions or tendency to distraction, but with practice you can lessen their impact.

Problem 2: Failing to Sustain Focus (aka Getting Distracted)

The second problem people tend to encounter is an inability to sustain focus. This can happen when you've sat yourself down to study or practice something, but then your phone buzzes and you look away, a friend knocks on the door to say hello, or you spin off into a daydream only to realize you've been staring at the same paragraph for the last fifteen minutes. Like the challenge of initiating focus, sustaining focus is important if you want to make progress learning hard things. Before I talk about how to sustain focus, however, I'd like to raise a question about what kind of focus is the best to sustain.

Flow, a concept pioneered by the psychologist Mihály Csíkszentmihályi, is often used as the model for what ideal focus looks like. This is the state of mind you associate with being "in the zone." You stop being interrupted by distracting thoughts, and your mind becomes completely absorbed in the task at hand. Flow is the enjoyable state that slides right between boredom and frustration, when a task is neither too hard nor too easy. This rosy picture, however, does have some detractors. The psychologist K. Anders Ericsson, the researcher behind deliberate practice, argues that flow has characteristics that are "inconsistent with the demands of deliberate practice for monitoring explicit goals and feedback and opportunities for error correction. Hence, skilled performers may enjoy and seek out flow experiences as part of their domain-related activities, but such experiences would not occur during deliberate practice."² Ultralearning, with its similar focus on performance-driven learning, would also appear to be unsuitable for flow, in the same way that Ericsson originally argued for deliberate practice.

My own thought is that a flow state is not impossible during ultralearning.

Many cognitive activities associated with learning are in the range of difficulty that makes flow possible or even likely. However, I also agree with Ericsson that learning often involves entering into situations in which the difficulty makes flow impossible. Additionally, the self-consciousness that is absent in flow may need to be present in both ultralearning and deliberate practice, as you need to consciously adjust your approach. Working on a programming problem at the limit of your abilities, pushing yourself to write in a style that is unfamiliar to you, or trying to minimize your accent when speaking a new language is each a task that goes against the automatic patterns you may have accumulated. This resistance to what is natural may make flow harder to achieve, even though it is ultimately beneficial for accomplishing your learning goal.

My advice? Don't worry about flow. In some learning tasks, you'll achieve it easily. I often felt as though I were in a flow state while doing practice problems during the MIT Challenge, drilling vocabulary while learning languages, or drawing. At the same time, don't feel guilty if flow doesn't come automatically. Your goal is to enhance your learning, and this often involves pushing through some sessions that are more frustrating than what could be considered ideal for flow. Remember, even if your learning is intense, your use of the skill later on will not be. Investments made in pushing through learning now will make skillful practice a much more enjoyable activity down the road.

After considering how you should focus, let's consider duration. How long should you study? While this problem presumes that you're getting distracted and giving up focusing long before you should, the literature on focus does not suggest that ever-longer periods of focus are optimal from a learning standpoint. Researchers generally find that people retain more of what they learn when practice is broken into different studying periods than when it is crammed together. Similarly, the phenomenon of interleaving suggests that even within a solid block of focus, it can make sense to alternate between different aspects of the skill or knowledge to be remembered.³ Therefore, if you have several hours to study, you're possibly better off covering a few topics rather than focusing exclusively on one. Doing so has trade-offs, however, so if your study time becomes more and more fractured, it may be difficult to learn at all.

What's needed is a proper balance. To achieve it, fifty minutes to an hour is a good length of time for many learning tasks. If your schedule permits only more concentrated chunks of time, say once per week for several hours, you may want to take several minutes as a break at the end of each hour and split your time over different aspects of the subject you want to learn. Of course, these are merely efficiency guidelines; you ultimately need to find what works best for you, considering not only what is optimal for the purposes of retention but also what fits your schedule, personality, and work flow. For some people, as little as twenty minutes might fit their lives best; others may prefer to spend an entire day learning.

Supposing that you've found a chunk of time to learn that is as optimal for you as it can be, how can you sustain your focus during that time? I've found that there are three different sources that cause focus to break down and distraction to occur. If you're struggling to concentrate, look at each of these three in turn.

Distraction Source 1: Your Environment

The first source of distraction is your environment. Do you have your phone

turned off? Are you accessing the internet, watching television, or playing games? Are there distracting noises and sounds? Are you prepared to work, or might you need to stop to look for pens, a book, or a lamp? This is a source of the problem of sustaining focus, but it's also an aspect people frequently ignore for the same reasons they ignore the fact that they are procrastinating. Many people tell themselves that they focus better while listening to music, let's say, but the reality might be that they don't want to work on a given task, so music provides a low-level, amusing distraction. This isn't to condemn anyone who doesn't work in a perfect environment. I certainly don't. Rather, be aware of what environment you work best in, and test it. Do you actually get more work done with the television on in the background, or do you just like hearing the television and feel that it makes the work more bearable? If it's the latter, you can probably train yourself to avoid multitasking and enjoy greater productivity. Multitasking may feel like fun, but it's unsuitable for ultralearning, which requires concentrating your full mind on the task at hand. It's better to rid yourself of this vice than to strengthen bad habits of ineffective learning.

Distraction Source 2: Your Task

The second source is the task you're trying to learn. Certain activities, due to their nature, are harder to focus on than others. I find reading harder to focus on than watching a video, even when the content is the same. Whenever you have a choice between using different tools for learning, you may want to consider which is easier to focus on when making that decision. This choice of materials shouldn't supersede other considerations—I wouldn't opt for a tool that is much less direct (Principle 3) or offers no feedback (Principle 6), simply for the sake of greater focus. Fortunately, these principles are generally aligned, and it is actually the somewhat less effective methods that are less cognitively demanding and therefore harder to sustain focus on. Sometimes you can subtly modify what you're doing to enable greater focus. If I have difficult reading to do, I will often make an effort to jot down notes that reexplain hard concepts for me. I do this mostly because, while I'm writing, I'm less likely to enter into the state of reading hypnosis where I'm pantomiming the act of reading while my mind is actually elsewhere. More intense strategies, whether solving problems, making something, or writing and explaining ideas aloud, are harder to do in the background of your mind, so there are fewer opportunities for distractions to creep in.

Distraction Source 3: Your Mind

The third source is your mind itself. Negative emotions, restlessness, and daydreaming can be some of the biggest obstacles to focus. This problem has two sides. First, it's obvious that a clear, calm mind is best for focusing on almost all learning problems. A mind filled with angers, anxieties, frustrations, or sadness will be harder to study with. This means that if you're struggling with problems in your life, you'll have a harder time learning well, and you may want to look at dealing with those first. Being in a toxic relationship, having anxiety about some other task you're procrastinating on, or simply knowing you're going down the wrong road in life can interfere with your motivation, so it's often best not to ignore these issues. However, sometimes there's nothing you can do about your emotions, and feelings arise spontaneously without requiring you to do something about them. A random worry about some future event might bubble up, let's say, but you know you shouldn't stop the activity you're working on right now in order to deal with it. Here the solution is to acknowledge the feeling, be aware of it, and gently

adjust your focus back to your task and allow the feeling to pass. Allowing negative feelings to pass, of course, is a lot easier said than done. Emotions can hijack the mind and make the process of returning awareness to your project feel like a Sisyphean task. If I'm really anxious about something, for instance, I may feel as though I'm returning my attention to a task, only for it to jump away fifteen seconds later, repeating again and again for an hour or more. In such moments, recognize that by not reacting to the emotion at the level of abandoning your task entirely, you'll diminish its intensity in the future. You'll also strengthen your commitment to continue working in future situations like this, so they will become easier. Mindfulness researcher and psychiatrist Susan Smalley and meditation teacher Diana Winston of UCLA's Mindful Awareness Research Center argue that when we are engaging in a behavior, our typical reaction is to try to suppress distracting thoughts. If instead you "learn to let it arise, note it, and release it or let it go," this can diminish the behavior you're trying to avoid.⁴ If it ever feels as though continuing working is pointless because you're so distracted by a negative emotion that you can't possibly work, remember that the long-term strengthening of your ability to persist on this task will be useful, so the time is not wasted even if you don't accomplish much in this particular learning session.

Problem 3: Failing to Create the Right Kind of Focus

A third, problem, subtler than the other two, has to do with the quality and direction of your attention. Supposing you've managed to wrangle the problems of procrastination and distraction down long enough to focus on your task, how should you do it? What's the optimal degree of alertness to maximize your learning?

Here there is some interesting research relating two different variables, arousal and task complexity, to the question of how you should apply your attention. Arousal (the general, not sexual, variety) is your overall feeling of energy or alertness. When you're sleepy, you have low arousal; when you're exercising, you have high arousal. This bodily phenomenon occurs due to sympathetic nervous system activation, and it consists of a range of effects in the body that often occur together, including faster heart rate, increased blood pressure, pupil dilation, and sweating. Mentally, arousal also influences attention. High arousal creates a feeling of keen alertness, which is often characterized by a fairly narrow range of focus, but one that can also be somewhat brittle.⁵ This can be very good for focusing on relatively simple tasks or ones that require intense concentration toward a small target.

Athletes require this kind of concentration to throw a dart at a target or shoot a basketball properly, where the task is fairly simple but requires concentration to execute properly. Too much arousal, however, and focus starts to suffer.⁶ It becomes very easy to be distracted, and you may have a hard time holding focus at any particular spot. Anyone who's drunk too much coffee and feels jittery knows how this can impact your work.

More complex tasks, such as solving math problems or writing essays, tend to benefit from a more relaxed kind of focus.⁷ Here the space of focus is often larger and more diffuse. This has advantages when, in order to solve the problem you're facing, you must consider many different inputs or ideas. Trying to solve a complex math problem or write a love sonnet is likely to require this mental quietness. When doing a particularly creative task, if you get stuck, you may benefit from no focus at all.⁸ Taking a break from the problem can widen the space of focus enough that possibilities that were not

in your consciousness earlier can conjoin and you can make new discoveries. This is a scientific explanation of “Eureka!” moments occurring during leisure or while falling asleep, instead of while at work. Still, before you begin to think that sloth is the key to creativity, it’s clear that such an approach often only works when one has been focusing on a problem for long enough that the residue of ideas remains in one’s mind. Not working at all is unlikely to lead to creative genius, but taking a break may help breathe fresh perspective into a hard problem.

The relationship between task complexity and arousal is interesting because the latter can be modified. In one experiment, sleep-deprived and well-rested subjects worked on a cognitive task.⁹ Unsurprisingly, the sleepy subjects didn’t do as well. More interesting, however, was that the sleepy subjects did better when a loud noise was played in the background, while the well-rested subjects did worse. The conclusion drawn by the researchers was that the noise increased arousal levels, which benefited the low-arousal sleepy subjects, but it increased arousal too much for the well-rested ones, causing their decline in performance. This implies that you may want to consider optimizing your arousal levels to sustain the ideal level of focus. Complex tasks may benefit from lower arousal, so working in a quiet room at home might be the right idea for math problems. Simpler tasks might benefit from a noisier environment, say working at a coffee shop. This laboratory experiment shows that you should find out what works best for your own ability to focus through self-testing. You may find you can work better on complex tasks even in the noisy coffee place, or you may find that even for simple tasks you need the quiet room in the library.

Improving Your Ability to Focus

Focus doesn’t need to be exclusive to the domain of those who have endless hours and large swaths of free time on their schedule. As was the case with Somerville, the ability to focus is even more important for those whose lives make such large commitments of time impossible. With practice you can improve your ability to focus. I’m agnostic about whether focus can be trained as an ability, in general. Just because you’re disciplined about one thing doesn’t automatically make you disciplined about everything else. However, what does generalize is that there is a procedure you can follow to get better at focusing. My advice is this: recognize where you are, and start small. If you’re the kind of person who can’t sit still for a minute, try sitting still for half a minute. Half a minute soon becomes one minute, then two. Over time, the frustrations you feel learning a particular subject may become transmuted into genuine interest. The impulse to engage in distractions will weaken each time you resist it. With patience and persistence, your few minutes may become large enough to accomplish great things, just as Somerville did almost two hundred years ago.

Now that we’ve discussed how to get started on learning hard things, let’s move to discussing the right way to learn them. The next principle, directness, is the first to explain what types of things you should do while learning and, more important, which you should avoid if you want to be able to use what you learn.

Chapter 6- Principle 3: Directness: Go Straight Ahead

After growing up in India, Vatsal Jaiswal moved to Canada with the dream of becoming an architect. Now, four years later, armed with a newly minted degree and entering into the worst job market since the Great Depression, that dream was beginning to seem very far away. Getting a foothold in architecture can be difficult, even in good economic times. But just a few years out from the market crash of 2007, it was nearly impossible. Firms were laying off even experienced architects. If anyone was hiring, they weren't taking chances on some kid just out of school. Out of his graduating class, almost nobody had found an architecture job yet. Most had given up, taking jobs outside the field, going back for more education, or moving in with parents until the economic storms abated.

Another rejection. Jaiswal leaves the offices of yet another architecture firm, walking back to his sliver of the one-bedroom apartment he shares with two roommates.¹ After hundreds of resumes submitted with no reply, he's moved on to trying a more aggressive tactic of going directly to a firm's offices, pleading to speak with whomever is in charge. Still, after weeks of knocking on doors and making dozens of unsolicited office visits, there's no job offer in sight. He hasn't even gotten a call back for a single interview. Still, Jaiswal suspected that his struggles could be blamed on more than just the recession. From the snippets of feedback he could pry out of the places he applied to, he sensed that the companies didn't see him as a useful employee. He had studied architecture in school, but his program had focused mostly on design and theory. He had been trained in creative design projects that were isolated from the reality of building codes, construction costs, and tricky software. Because his portfolio of school projects didn't resemble the detailed technical documents the architects worked with, they thought hiring him would involve a lengthy training period, something few firms could currently afford.

Jaiswal needed to come up with a plan. More resume submissions and office walk-ins weren't going to work. He needed a new portfolio that could prove he had the exact skills firms wanted. He needed to show them that, rather than being a burden, he could get to work straightaway and be a valuable team member from the first day.

To do this, he would need to know more about how architects actually drew plans for buildings—not just the big theories and designs, which he had learned in school, but little details of how they did their drawings, what codes they used to represent different materials, and what the drawings showed and omitted. To do that, he found a job at a large-format print shop, the kind that does printing on the large sheets of paper favored for architectural blueprints. Low paying and low skilled, a job in a print shop wasn't Jaiswal's end goal. Still, it could help him scrape by financially while he prepared his new portfolio. Even better, the print store gave him daily exposure to the blueprints firms were using. That allowed him to absorb countless details about how the drawings were put together.

Next, Jaiswal would need to upgrade his technical skills. From his walk-in visits, he was aware that many of the firms he was applying at were using a complex design software called Revit. If he could master its ins and outs, he thought, he could be immediately useful in the technology-heavy entry-level position he desired. At night, he pushed through online tutorials and taught

himself the software.

Finally, he was ready to construct a new portfolio. Combining his new Revit knowledge with the knowledge of architectural drawings he had gained while working at the print shop, he made a new portfolio. Instead of the assorted projects from university, he focused on a single building of his own design: a three-tower residential structure with raised courtyards and a modern aesthetic. The project pushed his skills with software further, forcing him to learn new methods and ideas beyond the basics of his online tutorials and exposure at the print shop. Eventually, after a few months of work, he was ready.

New portfolio in hand, Jaiswal submitted it again, this time to just two architecture firms. To his surprise, they both immediately offered him a job.

The Importance of Being Direct

Jaiswal's story perfectly illustrates the third principle of ultralearning: directness. By seeing how architecture was actually being done and learning a set of skills that was closely related to the job position he wanted to perform, he was able to cut through the swaths of recent graduates with unimpressive portfolios.

Directness is the idea of learning being tied closely to the situation or context you want to use it in. In Jaiswal's case, when he wanted to get enough architectural skill that firms would hire him, he opted to build a portfolio using the software those firms used and design in the style those firms practiced. There are many routes to self-education, but most of them aren't very direct. In contrast to Jaiswal, another architect I spoke with aimed to improve his employability by deepening his knowledge of design theories. Though that might have been interesting and fun, it was disconnected from the actual skills he would be using in entry-level work. Just as Jaiswal struggled to get work with his university portfolio, many of us are building the wrong portfolio of skills for the kinds of career and personal achievements we want to create. We want to speak a language but try to learn mostly by playing on fun apps, rather than conversing with actual people. We want to work on collaborative, professional programs but mostly code scripts in isolation. We want to become great speakers, so we buy a book on communication, rather than practice presenting. In all these cases the problem is the same: directly learning the thing we want feels too uncomfortable, boring, or frustrating, so we settle for some book, lecture, or app, hoping it will eventually make us better at the real thing.

Directness is the hallmark of most ultralearning projects.* Roger Craig did his Jeopardy! testing on the actual questions from past shows. Eric Barone learned video game art by making art for his video game. Benny Lewis learns to speak languages quickly by following a policy of attempting some backand-forth dialog from the very first day. What these approaches share is that the learning activities are always done with a connection to the context in which the skills learned will eventually be used.

The opposite of this is the approach so often favored in more traditional classroom-style learning: studying facts, concepts, and skills in a way that is removed from how those things will eventually be applied: mastering formulas before you understand the problem they're trying to solve; memorizing the vocabulary of a language because it's written on a list, not because you want to use it; solving highly idealized problems that you'll never see again after graduation.

Indirect approaches to learning, however, aren't limited to traditional

education. Many self-directed learners fall into the trap of indirect learning. Consider Duolingo, currently one of the most popular language-learning applications. On the surface, there's a lot to like about this app. It's colorful and fun and gives you a potent sense of progress. But I suspect that much of the sense of progress is an illusion, at least if your goal is to eventually be able to speak the language. To understand why, consider how Duolingo encourages you to practice. It provides English words and sentences and then asks you to pick words from a word bank to translate them.* The problem is that this is nothing like actually speaking a language! In real life, you may start by trying to translate an English sentence into the language you want to learn. However, real speaking situations don't present themselves as a multiple choice. Instead, you have to dredge up the actual words from memory or find alternative words if you haven't learned one of the ones you want to use. This is, cognitively speaking, quite a different task from picking out matching translations from a highly limited word bank, and also much more difficult. Benny Lewis's method of speaking from the start may be hard, but it transfers perfectly to the task he eventually wants to become good at: having conversations.

During the MIT Challenge, I recognized that the most important resource for being able to eventually pass the classes wasn't having access to recorded lectures, it was having access to problem sets. Yet, in the years since this project, when I am asked for help by students, they often decry the absence of lecture videos from some classes, only rarely complaining about incomplete or insufficient problem sets. This makes me think that most students view sitting and listening to a lecture as the main way that they learn the material, with doing problems that look substantially similar to those on the final exam as being a superficial check on their knowledge. Though first covering the material is often essential to begin doing practice, the principle of directness asserts that it's actually while doing the thing you want to get good at when much of learning takes place. The exceptions to this rule are rarer than they may first appear, and therefore directness has been a thorny problem in the side of education for over a century.

The easiest way to learn directly is to simply spend a lot of time doing the thing you want to become good at. If you want to learn a language, speak it, as Benny Lewis does. If you want to master making video games, then make them, as Eric Barone does. If you want to pass a test, practice solving the kinds of problems that are likely to appear on it, as I did in my own MIT Challenge. This style of learning by doing won't work for all projects. The "real" situation may be infrequent, difficult, or even impossible to create, and thus learning in a different environment is unavoidable. Roger Craig couldn't practice Jeopardy! by being on the show hundreds of times. He knew he had to learn in a different environment and prepare to transfer that knowledge to the show when it came time to do so. In such situations, directness isn't an all-or-nothing feature but something you can gradually increase to improve your performance. Craig's approach to start by learning from actual past Jeopardy! questions was a lot more effective than if he had just started learning trivia from random topics. Jaiswal was similarly limited when learning architectural skills, as the places he wanted to work wouldn't hire him. However, he worked around that by training on the same software they used and designing a portfolio that was based on the same types of drawings and renderings that were done in actual practice. The twin challenge of directness is that sometimes the exact situation in which you want to use the

skill isn't available for easy practice. Even if you can go straight into learning by doing, this approach is often more intense and uncomfortable than passively watching lecture videos or playing around with a fun app. If you don't pay attention to directness, therefore, it's very easy to slip into lousy learning strategies.

One of the big takeaways of Jaiswal's story might not be the triumph of his self-directed learning project but the failure of his formal education. After all, his difficulties started after he had already spent four years studying architecture intensely at university. Why, then, would such a small project, postgraduation, make such a large difference in his employability? To answer that, I'd like to turn to one of the most stubborn and disturbing problems in educational psychology: the problem of transfer.

Transfer: Education's Dirty Secret

Transfer has been called the "Holy Grail of education." It happens when you learn something in one context, say in a classroom, and are able to use it in another context, say in real life. Although this may sound technical, transfer really embodies something we expect of almost all learning efforts—that we'll be able to use something we study in one situation and apply it to a new situation. Anything less than this is hard to describe as learning at all.

Unfortunately, transfer is also something that, despite more than a century of intense work and research, has largely failed to occur in formal education. The psychologist Robert Haskell has said in his excellent coverage of the vast literature on transfer in learning, "Despite the importance of transfer of learning, research findings over the past nine decades clearly show that as individuals, and as educational institutions, we have failed to achieve transfer of learning on any significant level." He later added, "Without exaggeration, it's an education scandal."²

The situation is even more disturbing than it sounds. Haskell pointed out, "We expect that there will be transfer of learning, for example, from a high school course in introductory psychology to a college-level introduction to psychology course. It has been known for years, however, that students who enter college having taken a high school psychology course do no better than students who didn't take psychology in high school. Some students who have taken a psychology course in high school do even worse in the college course." In another study, college graduates were asked questions about economic issues and no difference in performance was found between those who had taken an economics class and those who had not.³

Providing multiple examples seems to aid transfer a bit, yet the cognitive science researcher Michelene Chi noted that "in almost all the empirical work to date, on the role of example solutions, a student who has studied examples often cannot solve problems that deviate slightly from the example solution."⁴

In his book *The Unschooled Mind: How Children Think and How Schools Should Teach*, the developmental psychologist Howard Gardner pointed to the body of evidence showing that even "students who receive honors grades in college-level physics courses are frequently unable to solve basic problems and questions encountered in a form slightly different from that on which they have been formally instructed and tested."⁵ Nor has this failure of transfer been limited to schools. Corporate training also suffers, with the former *Times Mirror* Training Group chairman John H. Zenger writing "Researchers who rigorously evaluate training have said that demonstrable changes following training are hard to find."⁶

The recognition of the failure of general transfer has a history as long as

the study of the problem itself. The first attack on the problem came from the psychologists Edward Thorndike and Robert Woodworth in 1901, with their seminal paper “The Influence of Improvement in One Mental Function upon the Efficiency of Other Functions.” In it, they attacked the dominant theory of education at the time, so-called formal discipline theory. This theory suggested that the brain was analogous to a muscle, containing fairly general capacities of memory, attention, and reasoning, and that training those muscles, irrespective of the content, could result in general improvement. This was the predominant theory behind universal instruction in Latin and geometry, on the idea that it would help students think better. Thorndike was able to refute this idea by showing that the ability to transfer was much narrower than most people had assumed.

Although studying Latin has fallen out of favor, many educational pundits are reviving new incarnations of the formal discipline theory by suggesting that everyone learn programming or critical thinking in order to improve their general intelligence. Many popular “brain-training” games also subscribe to this view of the mind, assuming that deep training on one set of cognitive tasks will extend to everyday reasoning. It’s been more than one hundred years since the verdict came in, yet the allure of a general transfer procedure still has many searching for the Holy Grail.

Despite all this, the situation isn’t without hope. Although empirical work and educational institutions have often failed to demonstrate significant transfer, it is not the case that transfer doesn’t exist. Wilbert McKeachie, in reviewing the history of transfer, noted that “Transfer is paradoxical. When we want it, we do not get it. Yet it occurs all the time.”⁷ Whenever you use an analogy, saying something is like something else, you’re transferring knowledge. If you know how to ice skate and later learn to Rollerblade, you’re transferring skills. As Haskell pointed out, if transfer were really impossible, we would be unable to function.

So what explains the disconnect? Why have educational institutions struggled to demonstrate significant transfer, if transfer is something we all need to function in the world? Haskell suggests that a major reason is that transfer tends to be harder when our knowledge is more limited. As we develop more knowledge and skill in an area, they become more flexible and easier to apply outside the narrow contexts in which they were learned. However, I’d like to add my own hypothesis as an explanation for the transfer problem: most formal learning is woefully indirect.

Overcoming the Problem of Transfer with Directness

Directness solves the problem of transfer in two ways. The first and most obvious is that if you learn with a direct connection to the area in which you eventually want to apply the skill, the need for far transfer is significantly reduced. Given a century of research showing the difficulties of transfer along with proposed solutions that have failed to provide lasting results, any student must take seriously the notion that transferring what has been learned between very different contexts and situations will be treacherous. If our learning is, as Haskell suggests, “welded to a place or subject matter,” it is a lot better that those situations be close to the ones we actually want to use. Second, I believe that directness may help with transfer to new situations, beyond its more obvious role in preventing the need for far transfer. Many real-life situations share many subtle details with other real-life situations that they never share with the abstract environment of the classroom or textbook. Learning something new rarely depends just on the mass of easily articulated

and codified knowledge present but on the myriad tiny details of how that knowledge interacts with reality. By learning in a real context, one also learns many of the hidden details and skills that are far more likely to transfer to a new real-life situation than from the artificial environment of a classroom. Using a personal example, one of the skills I found most important in the no-English project was being able to quickly use a dictionary or translation app on my phone, so I could fill gaps in my linguistic knowledge in midconversation. However, it's exactly this kind of practical skill that is rarely covered in a language-learning curriculum. While this is a trivial example, real-life situations contain thousands of such pieces of skill and knowledge that are necessary if you're going to apply academically learned subjects in the real world.

Ultimately, it will be for researchers to decide whether the Holy Grail of education will ever be found. In the meantime, as learners, we must accept that initial learning efforts often stick stubbornly to the situations we learn them in. The programmer who learns about an algorithm from a class may have trouble recognizing when to use it in her code. The leader who learns a new management philosophy from a business book may go back to working with the same approach she has always used with her employees. My favorite example, though, has to be when a group of friends invited me to join them at a casino. I asked them if their studies ever kept them from enjoying gambling, and they just looked at me blankly. I thought it was funny because the students were actuaries. Their years spent studying statistics in the classroom should have convinced them that you can't expect to beat the house, yet that connection didn't seem to dawn on them. When we learn new things, therefore, we should always strive to tie them directly to the contexts we want to use them in. Building knowledge outward from the kernel of a real situation is much better than the traditional strategy of learning something and hoping that we'll be able to shift it into a real context at some undetermined future time.

How Ultralearners Avoid the Problem of Transfer and Learn Directly

Given the problem of transfer and the importance of learning directly, let's look at some of the ways that this is managed in different ultralearning projects. The simplest way to be direct is to learn by doing. Whenever possible, if you can spend a good portion of your learning time just doing the thing you want to get better at, the problem of directness will likely go away. If this isn't possible, you may need to create an artificial project or environment to test your skills. What matters most here is that the cognitive features of the skill you're trying to master and the way you practice it be substantially similar. Consider again Craig's simulation of Jeopardy! games by doing questions from old tests. The fact that he was using actual past questions is more important than whether his program matched the signature blue background color present on the show's display. This is because the background color didn't provide any information that would have changed his responses to the questions. The skill he was practicing wasn't changed much by it. In contrast, if he had taken trivia questions from a different game (say the board game Trivial Pursuit) there might have been differences in how questions are typically asked, the topics they are drawn from, or the difficulty level. Worse, if he had spent all his time reading random Wikipedia articles to learn trivia, he wouldn't have been practicing the fundamental skill of recalling answers based on cryptic Jeopardy!-style clues at all.

In other cases, what you're trying to achieve may not be a practical skill. Many of the ultralearners I encountered wanted, as their end goal, to understand a subject particularly well, such as Vishal Maini with machine learning and artificial intelligence. Even my own MIT Challenge was based around gaining a deep understanding of computer science, as opposed to a more practical goal of building an app or video game. Though this may seem like a case where directness no longer matters, that really isn't true. It's simply that the place you want to apply these ideas is less obvious and concrete. In Maini's case, he wanted to be able to think and talk intelligently about machine learning, enough to be able to land a nontechnical role in a company that utilized those methods. That meant that being able to communicate his ideas articulately, understanding the concepts clearly, and being able to discuss them with both knowledgeable practitioners and laypeople was important. That's why his goal to make a minicourse explaining the basics of machine learning fit so well. His learning was directly connected with where he wanted to apply the skill: communicating it to others.

Although the findings of the research on transfer are fairly bleak, there is a glimmer of hope, which is that gaining a deeper knowledge of a subject will make it more flexible for future transfer. Whereas the structures of our knowledge start out brittle, welded to the environments and contexts we learn them in, with more work and time they can become flexible and can be applied more broadly. This is the conclusion of Robert Haskell, and although it does not provide a short-term solution to the problem for new learners, it does suggest a path out for those who want to continue working on a subject until they master it. Many ultralearners who have specialized in a smaller subset of fields are masters at transfer; no doubt this is largely due to their depth of knowledge, which makes transfer easier to accomplish. Dan Everett, who was featured in the opening of the chapter on the first principle, metalearning, is a prime example of this. His linguistic depth allows him to learn new languages relatively easily, compared to someone who has learned only a second language or has learned only languages academically.

How to Learn Directly

Given the well-documented difficulty with indirect forms of learning, why are they still the default both in schools and in many failed attempts at selfeducation? The answer is that learning directly is hard. It is often more frustrating, challenging, and intense than reading a book or sitting through a lecture. But this very difficulty creates a potent source of competitive advantage for any would-be ultralearner. If you're willing to apply tactics that exploit directness despite these difficulties, you will end up learning much more effectively.

Let's examine some of the tactics ultralearners use to maximize this principle and take advantage of the inadequacies of more typical schooling.

Tactic 1: Project-Based Learning

Many ultralearners opt for projects rather than classes to learn the skills they need. The rationale is simple: if you organize your learning around producing something, you're guaranteed to at least learn how to produce that thing. If you take classes, you may spend a lot of time taking notes and reading but not achieve your goal.

Learning to program by creating your own computer game is a perfect example of project-based learning. Engineering, design, art, musical composition, carpentry, writing, and many other skills naturally lend

themselves to projects that produce something at the end. However, an intellectual topic can also be the basis of a project. One ultralearner I interviewed, whose project is still ongoing, wanted to learn military history. His project, in this case, was to work toward producing a thesis paper. Since his end goal was to be able to converse knowledgeably about the subject, a project to produce an original paper applied learning more directly than simply trying to read a lot of books without creating anything.

Tactic 2: Immersive Learning

Immersion is the process of surrounding yourself with the target environment in which the skill is practiced. This has the advantage of requiring much larger amounts of practice than would be typical, as well as exposing you to a fuller range of situations in which the skill applies.

Learning a language is the canonical example of where immersion works. By immersing yourself in an environment where a language is spoken, not only do you guarantee that you'll end up practicing the language a lot more than you would otherwise (since you have no choice), but you also face a broader diversity of situations that require learning new words and phrases. However, language learning is not the only place where you can apply immersion to learn more. Joining communities of people who are actively engaged in learning can have a similar impact, since it encourages constant exposure to new ideas and challenges. For example, novice programmers might join open-source projects to expose themselves to new coding challenges.

Tactic 3: The Flight Simulator Method

Immersion and projects are great, but for many skills there's no way to actually practice the skill directly. For skills such as piloting a plane or performing surgery, it's not even legal to practice them in a real situation until you've already invested considerable time into training. How can you overcome this?

It's important to note that what matters for transfer is not every possible feature of the learning environment, such as what room you're in or what clothes you're wearing while you learn. Rather, it's the cognitive features—situations where you need to make decisions about what to do and cue knowledge you've stored in your head. This suggests that when direct practice is impossible, a simulation of the environment will work to the degree to which it remains faithful to the cognitive elements of the task in question. For flying a plane, this means that practicing on a flight simulator may be as good for learning as flying an actual plane if it sufficiently calls on the discriminations and decisions a pilot needs to make. Better graphics and sounds aren't important, unless they change the nature of the decisions being made or the cues pilots receive for when to use certain skills or knowledge.⁸ When evaluating different methods for learning, those that significantly simulate the direct approach will transfer a lot better. Therefore, if you're trying to evaluate what's the best way to learn French before your trip to France, you'll get more (although not perfect) transfer from doing Skype tutoring than you will from flipping through flash cards.

Tactic 4: The Overkill Approach

The last method I've found for enhancing directness is to increase the challenge, so that the skill level required is wholly contained within the goal that is set. Tristan de Montebello, when preparing to compete in the World Championship of Public Speaking, pushed to speak at middle schools, giving early versions of his talk. His feeling was that the feedback he received at

Toastmasters clubs might be too soft or congratulatory to cut deep at what worked and didn't work in his speech. Middle school students, in contrast, would be merciless. If a joke he said wasn't funny or his delivery was boring or cheesy, he would be able to tell immediately from their faces what needed to be reworked. The overkill approach is to put yourself into an environment where the demands are going to be extremely high, so you're unlikely to miss any important lessons or feedback.

Going into this environment can feel intense. You may feel as though you're "not ready" to start speaking a language you've barely learned. You may be afraid to stand onstage and deliver a speech you haven't memorized perfectly. You might not want to dive right into programming your own application and prefer to stick to watching videos where someone else does the coding. But these fears are often only temporary. If you can get enough motivation to start this method, it's often a lot easier to continue it long term. The first week in each new country in my language learning project was always a shock, but soon it became completely normal to live entirely within the new language.

One way you can overkill a project is to aim for a particular test, performance, or challenge that will be above the skill level you strictly require. Benny Lewis likes to attempt language exams, because they provide a concrete challenge. In his German project, he wanted to attempt the highest level exam, because his awareness of that goal would push him to study more than he might if he were satisfied with comfortable conversations alone. Another friend of mine decided to exhibit her photography as a means of pushing her skills and talent. Deciding in advance that your work will be viewable publicly alters your approach to learning and will gear you toward performance in the desired domain, rather than just checking off boxes of facts learned.

Learn Straight from the Source

Learning directly is one of the hallmarks of many of the successful ultralearning projects I've encountered, particularly because of how different it can be from the style of education most of us are used to. Whenever you learn anything new, it's a good habit to ask yourself where and how the knowledge will manifest itself. If you can answer that, you can then ask whether you're doing anything to tie what you're learning to that context. If you're not, you need to tread carefully, as the problem of transfer may rear its ugly head.

The act of learning directly, however, is only half of the answer to the question of what you should do to learn well. Doing a lot of direct practice in the environment where you want to eventually use your skills is an important start. However, in order to master skills quickly, bulk practice isn't enough. This brings us to our next principle of ultralearning: drill.

Chapter 7: Principle 4: Drill: Attack Your Weakest Point

Of all the roles Benjamin Franklin played throughout his life—entrepreneur, inventor, scientist, diplomat, and founding father of the United States—he was first and foremost a writer. It was in writing that he first found success. After fleeing Boston to escape the final years of his indentured labor as an apprentice to his brother's printing company, he went to Philadelphia. There, penniless and unknown, he first worked for another printing company before establishing himself as a competitor. His *Poor Richard's Almanack* became an international bestseller and allowed him to retire at forty-two. However, it was in the latter half¹ of his life that his writing would have world-changing consequences.²

As a scientist, Franklin was bad at math and more interested in practical consequences than in grand theories of the universe. However, his prose was “written equally well for the uninitiated as well as the philosopher,” noted the English chemist Sir Humphrey Davy, adding “he has rendered his details as amusing as well as perspicuous.”³ The strength of his writing and its practical consequences made him an international sensation.

In politics, it was again Franklin's writing talent that helped him win allies and persuade potential antagonists. Prior to the American Revolution, he penned an essay, supposedly written by King Frederick II of Prussia, entitled “An Edict by the King of Prussia.” In it he satirized British-American relations by proposing that, due to early settlers of the British Isles being of German origin, “revenue [should] be raised from said colonies in Britain” by the Prussian king.

Later, his skill with a pen would make his writing into the Declaration of Independence, where he edited Thomas Jefferson's words to become the now famous “We hold these truths to be self-evident.”

With such an amazing skill for writing and persuasion, it's worth asking how Franklin acquired it. Fortunately, unlike so many other great writers, whose efforts at honing their skills remain mysterious, we have Franklin's own words for how he did it. In his *Autobiography*, he details his sophisticated efforts to slice apart sections of his writing skill for practice as a young boy. Beginning with a childhood debate against a friend about the merits of educating women (Franklin was for, his friend against), his father noticed that aspects of his writing lacked persuasive ability. Franklin thus “determined to endeavor at improvement” and went about a series of exercises to practice his writing skill.

One such exercise he documents was taking a favorite magazine of his, *The Spectator*, and taking notes on articles that appeared there. He would then leave the notes for a few days and come back to them, trying to reconstruct the original argument from memory. After finishing, he “compared my *Spectator* with the original, discovered some of my faults, and corrected them.” Realizing that his vocabulary was limited, he developed another strategy. By turning the prose into verse, he could replace words with synonyms that matched in meter or rhyme. To improve his sense of the rhetorical flow of an essay, he tried his imitation approach again, but this time he jumbled up the hints so he would have to determine the correct order of the sequence of ideas as he wrote again.

Once he had established some of the mechanics of writing, he moved on to the more difficult task of writing in a style that would persuade. When

reading an English grammar book, he was exposed to the idea of the Socratic method, of challenging another's ideas through probing questions rather than direct contradiction. He then went to work, carefully avoiding "abrupt contradiction and positive argumentation," instead focusing on being the "humble inquirer and doubter."

Those early efforts produced results. At age sixteen, he wanted to try to get his work published. Fearing that his elder brother might reject it out of hand, however, he disguised his penmanship and submitted his essay under the pseudonym Silence Dogood, purporting to be a widowed woman living in the countryside. His brother, not knowing the true author, approved and published the essay, so Franklin returned and wrote more. Although initiated as a ruse to have his writing considered fairly, Franklin's practice in adopting other characters would prove invaluable in his later career. Poor Richard's Almanack, for example, was written from the perspective of a simple husband and wife, Richard and Bridget Saunders, and his political essays such as his "An Edict by the King of Prussia" similarly made use of his flexibility to adopt imagined perspectives.

It's difficult to imagine Franklin having become the household name he is today without his having first established a mastery of writing. Whether it was business, science, or statecraft, the unchanging core of what made him persuasive and great was his ability to write well. What distinguished Franklin wasn't merely the amount he wrote or his raw talent but how he practiced. The way in which he decided to break apart the skill of writing and practice its elements in isolation enabled him to master writing at a young age and apply it to the other pursuits for which he would later become famous. Such careful analysis and deliberate practice forms the basis for the fourth ultralearning principle: drill.

The Chemistry of Learning

In chemistry, there's a useful concept known as the rate-determining step. This occurs when a reaction takes place over multiple steps, with the products of one reaction becoming the reagents for another. The rate-determining step is the slowest part of this chain of reactions, forming a bottleneck that ultimately defines the amount of time needed for the entire reaction to occur. Learning, I'd like to argue, often works similarly, with certain aspects of the learning problem forming a bottleneck that controls the speed at which you can become more proficient overall.

Consider learning mathematics. This is a complex skill that has many different parts: you need to be able to understand the fundamental concepts, you need to be able to remember the algorithm for solving a certain type of problem, and you need to know in what context it applies. Underlying this ability, however, is the ability to do arithmetic and algebra so as to be able to solve the problems in question. If your arithmetic is weak or your algebra sloppy, you'll get the wrong answers even if you've mastered the other concepts.

Another rate-determining step could be vocabulary when learning a foreign language. The number of sentences you can successfully utter depends on how many words you know. If you know too few, you won't be able to talk about very much. If you were able to suddenly inject hundreds of new words into your mental database, you might drastically expand your fluency even if your pronunciation, grammar, or other linguistic knowledge remains unchanged.

This is the strategy behind doing drills. By identifying a rate-determining

step in your learning reaction, you can isolate it and work on it specifically. Since it governs the overall competence you have with that skill, by improving at it you will improve faster than if you try to practice every aspect of the skill at once. That was Franklin's insight that allowed him to rapidly improve his writing: by identifying components of the overall skill of writing, figuring out which mattered in his situation, and then coming up with clever ways to emphasize them in his practice, he could get better more quickly than if he had just spent a lot of time writing.

Drills and Cognitive Load

Rate-determining steps in learning—where one component of a complex skill determines your overall level of performance—are a powerful reason to apply drills. However, they aren't the only one. Even if there isn't one isolatable aspect of the skill that is holding back your performance, it may still be a good idea to apply drills.

The reason is that when you are practicing a complex skill, your cognitive resources (attention, memory, effort, etc.) must be spread over many different aspects of the task. When Franklin was writing, he had to consider not only the logical content of the argument he was making but word choice and rhetorical style. This can create a learning trap. In order to improve your performance in one aspect, you may need to devote so much attention to that one aspect that the other parts of your performance start to go down. If you can judge yourself only on how much you improve at the overall task, it can lead to a situation in which your improvement slows down because you will be getting worse at the overall task while becoming better at a specific component of it.

Drills resolve this problem by simplifying a skill enough that you can focus your cognitive resources on a single aspect. When Franklin focused on reconstructing the order of an essay he had read previously, he could devote all his attention to asking what sequence of ideas leads to a good essay rather than also needing to worry about word usage, grammar, and the content of the arguments.

Astute readers will probably notice a tension between this principle and the last. If direct practice involves working on a whole skill nearest to the situation in which it will eventually be used, drills are a pull in the opposite direction. A drill takes the direct practice and cuts it apart, so that you are practicing only an isolated component. How can you resolve this contradiction?

The Direct-Then-Drill Approach

The tension between learning directly and doing drills can be resolved when we see them as being alternating stages in a larger cycle of learning. The mistake made in many academic strategies for learning is to ignore the direct context or abstract it away, in the hope that if enough component skills are developed, they will eventually transfer. Ultralearners, in contrast, frequently employ what I'll call the Direct-Then-Drill Approach.

The first step is to try to practice the skill directly. This means figuring out where and how the skill will be used and then trying to match that situation as close as is feasible when practicing. Practice a language by actually speaking it. Learn programming by writing software. Improve your writing skills by penning essays. This initial connection and subsequent feedback loop ensure that the transfer problem won't occur.

The next step is to analyze the direct skill and try to isolate components that are either rate-determining steps in your performance or subskills you

find difficult to improve because there are too many other things going on for you to focus on them. From here you can develop drills and practice those components separately until you get better at them.

The final step is to go back to direct practice and integrate what you've learned. This has two purposes. The first is that even in well-designed drills, there are going to be transfer hiccups owing to the fact that what was previously an isolated skill must be moved to a new and more complex context. Think of this as being like building the connective tissue to join the muscles you strengthened separately. The second function of this step is as a check on whether your drill was well designed and appropriate. Many attempts to isolate a drill may end in failure because the drill doesn't really cut at the heart of what was difficult in real practice. That's okay; this feedback is important to help you minimize wasting time learning things that don't matter much to your end goals.

The earlier you are in the learning process, the faster this cycle should be. Cycling between direct practice and drills, even within the same learning session, is a good idea when you're just starting out. Later, as you get better at what you are trying to do and a lot more effort is required to noticeably improve your overall performance, it's more acceptable to take longer detours into drills. As you approach mastery, your time may end up focused mostly on drills as your knowledge of how the complex skill breaks down into individual components becomes more refined and accurate and improving any individual component gets harder and harder.

Tactics for Designing Drills

There are three major problems when applying this principle. The first is figuring out when and what to drill. You should focus on what aspects of the skill might be the rate-determining steps in your performance. Which aspect of the skill, if you improved it, would cause the greatest improvement to your abilities overall for the least amount of effort? Your accounting skills might be limited by the fact that your Excel knowledge is superficial, which prevents you from applying all the things you know to practical situations. Your language abilities may be held back by having inaccurate pronunciation, even though you know the right words. Look as well to aspects of a skill that you need to juggle simultaneously. These may be harder to improve because you can't devote enough cognitive resources to improving them. When writing a new article, you may have to juggle research, storytelling, vocabulary, and many other aspects simultaneously, making it hard to get a lot better at just one. Determining what to drill may seem tricky, but it doesn't have to be. The key is to experiment. Make a hypothesis about what is holding you back, attack it with some drills, using the Direct-Then-Drill Approach, and you can quickly get feedback about whether you're right.

The second difficulty with this principle is designing the drill to produce improvement. This is often hard because even if you recognize an aspect of your performance you're weak on, it may be tricky to design a drill that trains that component without artificially removing what makes it difficult in actual application. Franklin's drills were uncommon, I believe, because most people, even recognizing specific deficits in their writing ability, would not have had the ingenuity to find ways to drill subskills such as ordering arguments persuasively and emulating a successful writing style.

Finally, doing drills is hard and often uncomfortable. Teasing out the worst thing about your performance and practicing that in isolation takes guts. It's

much more pleasant to spend time focusing on things you're already good at. Given this natural tendency, let's look at some good ways to do drills so you can start applying them yourself.

Drill 1: Time Slicing

The easiest way to create a drill is to isolate a slice in time of a longer sequence of actions. Musicians often do this kind of training when they identify the hardest parts of a piece of music and practice each one until it's perfect before integrating it back into the context of the entire song or symphony. Athletes similarly engage in this process when they drill skills that are normally a fraction of total playing time, such as layups or penalty shots. In the early phase of learning a new language, I often obsessively repeat a few key phrases, so they quickly get embedded into my long-term memory. Look for parts of the skill you're learning that can be decomposed into specific moments of time that have heightened difficulty or importance.

Drill 2: Cognitive Components

Sometimes what you'll want to practice isn't a slice in time of a larger skill but a particular cognitive component. When speaking a language, grammar, pronunciation, and vocabulary occur at all moments, but they form different cognitive aspects that must be managed simultaneously. The tactic here is to find a way to drill only one component when, in practice, others would be applied at the same time. When learning Mandarin Chinese, I would do tone drills that involved pronouncing pairs of words with different tones and recording myself speaking. That allowed me to practice producing different tones quickly, without the distraction of needing to remember what the words meant or how to form grammatically correct sentences.

Drill 3: The Copycat

A difficulty with drills in many creative skills is that it is often impossible to practice one aspect without also doing the work of the others. When Franklin was trying to improve his ability to order arguments logically, for instance, it wasn't possible to do so without writing an entire essay. To solve this problem in your own learning, you can take a page from Franklin: by copying the parts of the skill you don't want to drill (either from someone else or your past work), you can focus exclusively on the component you want to practice. Not only does this save a lot of time, because you need to repeat only the part you're drilling, it also reduces your cognitive burden, meaning you can apply more focus to getting better at that one aspect. When practicing drawing, I started by drawing not just from photos but from drawings other people had done. That helped me focus on the skill of accurately rendering the picture, simplifying the decision about how to frame the scene and which details to include. For flexible creative works, editing works you've created in the past may have the same effect, allowing you to selectively improve an aspect of your work without having to consider the other demands of an original composition.

Drill 4: The Magnifying Glass Method

Suppose you need to create something new and can't edit or separate out the part you want to practice. How can you create a drill? The Magnifying Glass Method is to spend more time on one component of the skill than you would otherwise. This may reduce your overall performance or increase your input time, but it will allow you to spend a much higher proportion of your time and cognitive resources on the subskill you want to master. I applied this method when trying to improve my ability to do research when writing articles, by spending about ten times as long on research as I had previously.

Although I still had to do all the other parts of writing the article, by spending much longer on research than I would normally, I could develop new habits and skills for doing so.

Drill 5: Prerequisite Chaining

One strategy I've seen repeatedly from ultralearners is to start with a skill that they don't have all the prerequisites for. Then, when they inevitably do poorly, they go back a step, learn one of the foundational topics, and repeat the exercise. This practice of starting too hard and learning prerequisites as they are needed can be frustrating, but it saves a lot of time learning subskills that don't actually drive performance much. Eric Barone, for instance, started his pixel art experiments simply by making them. When he struggled with certain aspects, such as colors, he went back, learned color theory, and repeated his work. Benny Lewis has a similar habit of starting with speaking from a phrase book and only later learning the grammar that explains how the phrases function.

Mindful Drilling

To many, the idea of drilling may seem to be a push in the wrong direction. We've all spent time doing homework designed to drill into us facts and procedures that turned out to be a total waste of time. That was often because we didn't know the reasons behind what we were practicing or how it fit into a broader context. Drilling problems without context is mind-numbing. However, once you've identified that it's the bottleneck preventing you from going further, they become instilled with new purpose. In ultralearning, which is directed by the student, not an external source, drills take on a new light. Instead of being forced to do them for unknown purposes, it is now up to you to find a way to enhance the learning process by accelerating learning on the specific things that you find most difficult. In this sense, drills take on a very different flavor in ultralearning as opposed to traditional learning. Far from being meaningless drudgery, carefully designed drills elicit creativity and imagination as you strive to solve a more complex learning challenge by breaking it into specific parts.

Drills are hard to do, which is why many of us would rather avoid them. When we do engage in drills, it's often in subjects where we feel competent and comfortable. Drills require the learner not only to think deeply about what is being learned but also figure out what is most difficult and attack that weakness directly rather than focus on what is the most fun or what has already been mastered. This requires strong motivation and a comfort with learning aggressively. Franklin, in his Autobiography, remarked about the lengths he went to so he could dedicate himself to his writing drills: "My time for these exercises and for reading was at night, after work or before it began in the morning." Despite the prominence writing would play in his life, Franklin still had to work long hours under his taskmaster brother in the print shop, diligently improving his craft in what little leisure time he had. Eric Barone similarly repeated his pixel art dozens of times, going back to master prerequisite concepts and theory until he got it perfect.

The difficulty and usefulness of drills repeat a pattern that will recur throughout the ultralearning principles: that something mentally strenuous provides a greater benefit to learning than something easy. Nowhere is this pattern more clear than in the next principle, retrieval, where difficulty itself may be the key to more effective learning.

Chapter 8- Principle 5; Retrieval: Test To Learn

In the spring of 1913, the mathematician G. H. Hardy received a letter that would forever define the course of his life. Sent by an accounting clerk working for the Port Trust Office of Madras in India, the letter contained a humble note of introduction along with some startling assertions. The author claimed that he had found theorems for problems that the best mathematical minds of the time had yet to solve. What's more, he claimed that he had "no University education" and had derived these results from his own solitary investigations.¹

Receiving letters from amateur crackpots who claimed to have solutions to famous problems was a common occurrence for someone of Hardy's stature in mathematics, so at first he simply dismissed the letter as being more of the same. Still, flipping through the several pages of notes attached to the letter, the equations wouldn't leave his mind. When he found himself thinking about them hours later, he brought the letter to the attention of his colleague John Littlewood. As the two of them toyed at trying to prove the strange assertions, they found that some of them they were able to prove with great effort, while others remained, in Hardy's words, "scarcely possible to believe." Maybe, Hardy thought, this wasn't a letter from a crackpot but something rather different.

The formulas written were so bizarre and alien that Hardy remarked, "They must be true because, if they were not true, no one would have had the imagination to invent them." What he only vaguely understood that day was that he had just had his first introduction to one of the most brilliant and bizarre mathematicians of all time, Srinivasa Ramanujan.

Ramanujan's Genius

Before writing his letter to Hardy, which changed the course of mathematical history, Ramanujan was a poor, pudgy south Indian boy with a special love of equations. More than anything else, he loved math. In fact, his love of math often got him into difficulties. His unwillingness to study other subjects flunked him out of university. Equations were all he cared about. In his spare time and during stretches of unemployment, he would sit for hours on the bench in front of his family home, slate in hand, playing with formulas. Sometimes he would stay up so late that his mother would need to put food into his hand so he would eat.

As he was thousands of miles away from the center of mathematics of his day, access to high-quality textbooks was quite a challenge for Ramanujan. One resource he did encounter and mined extensively was a volume by George Shoobridge Carr called *A Synopsis of Elementary Results in Pure and Applied Mathematics*. Carr himself was hardly a towering figure of mathematical genius. The book, intended as a guide for students, included large lists of various theorems from different fields of mathematics, usually without explanation or proof. However, even without having proofs or explanations available, Carr's book became a powerful resource in the hands of someone smart and obsessed like Ramanujan. For instead of simply copying and memorizing how certain theorems were derived, he had to figure them out for himself.

Though many commentators of the time, including Hardy, argued that Ramanujan's impoverished upbringing and late access to the cutting edge of mathematics likely did irreparable harm to his genius, modern psychological

experiments may offer an alternative perspective, for when Ramanujan dealt only with Carr's extensive list of theorems using his own quirky obsession with mathematical formulas, he was unwittingly practicing one of the most powerful methods known to build a deep understanding.

The Testing Effect

Imagine you're a student preparing for an exam. You have three choices about how you can allocate your limited studying time. First, you can review the material. You can look over your notes and book and study everything until you're sure you'll remember it. Second, you can test yourself. You can keep the book shut and try to remember what was in it. Finally, you can create a concept map. You can write out the main concepts in a diagram, showing how they're organized and related to other items you need to study. If you can pick only one, which one should you choose to do best on the final exam?

This is essentially the question posed by the psychologists Jeffrey Karpicke and Janell Blunt in one study examining students' choice of learning strategy.² In the study, students were divided into four groups, each given the same amount of time but told to use different study strategies: reviewing the text a single time, reviewing it repeatedly, free recall, and concept mapping. In each group, students were asked to predict their score on the upcoming test. Those who did repeated reviewing predicted that they'd score the best, followed by the single-study and concept-mapping groups. Those who practiced free recall (trying to remember as much as they could without looking in the book) predicted the worst for their final performance. The actual results, however, weren't even close. Testing yourself—trying to retrieve information without looking at the text—clearly outperformed all other conditions. On questions based directly on the content of the text, those who practiced free recall remembered almost 50 percent more than the other groups. How could students, who have spent years getting firsthand experience about what matters to learning, be so misguided about what actually produces results?

One might be tempted to argue that this benefit of self-testing is an artifact of the way success is measured. The principle of directness asserts that transfer is difficult. Since self-testing and actual testing are most similar, perhaps it is this similarity that allows this method to work better. Had the method of evaluation differed, it might be reasonable to suspect that review or concept mapping might come out on top. Interestingly, in another experiment, Karpicke and Blunt showed that this wasn't the explanation, either. In this experiment the final test was to produce a concept map. Despite the overwhelming similarity to the evaluation task, free recall still did better than using concept mapping to study.

Another possible explanation for why self-testing works is feedback. When you review something passively, you don't get any feedback about what you know and don't know. Since tests usually come with feedback, that might explain why students who practiced self-testing beat the concept mappers or passive reviewers. Though it is true that feedback is valuable, once again, retrieval doesn't simply reduce down to getting more feedback. In the experiments mentioned, students were asked to do free recall but weren't provided any feedback about items they missed or got wrong. The act of trying to summon up knowledge from memory is a powerful learning tool on its own, beyond its connection to direct practice or feedback.

This new perspective on learning shows how Carr's book, with its lists of

proofs without solutions, could have become, in the hands of someone sufficiently motivated to master them, an incredible tool for becoming brilliant at math. Without the answers at hand, Ramanujan was forced to invent his own solutions to the problems, retrieving information from his mind rather than reviewing it in a book.

The Paradox of Studying

If retrieval practice—trying to recall facts and concepts from memory—is so much better for learning, why don't students realize it? Why do many prefer to stick to concept mapping or the even less effective passive review, when simply closing the book and trying to recall as much as possible would help them so much more?

Karpicke's research points to a possible explanation: Human beings don't have the ability to know with certainty how well they've learned something. Instead, we need to rely on clues from our experience of studying to give us a feeling about how well we're doing. These so-called judgments of learning (JOLs) are based, in part, on how fluently we can process something. If the learning task feels easy and smooth, we are more likely to believe we've learned it. If the task feels like a struggle, we'll feel we haven't learned it yet. Immediately after spending some time studying, these JOLs may even be accurate. Minutes after studying something using a strategy of passive review, students perform better than they would if they had practiced retrieval.³ The feeling that you're learning more when you're reading rather than trying to recall with a closed book isn't inaccurate. The problem comes after. Test again days later, and retrieval practice beats passive review by a mile. What helped in the immediate time after studying turns out not to create the long-term memory needed for actual learning to take place.

Another explanation for why students opt for low-efficiency review instead of retrieval is that they don't feel they know the material well enough to test themselves on it. In another experiment, Karpicke had students choose a strategy for learning. Inevitably, students who were performing more weakly elected to review the material first, waiting until they were "ready" to start practice testing.⁴ If through experimental intervention, however, they were forced to practice retrieval earlier, they learned more. Whether you are ready or not, retrieval practice works better. Especially if you combine retrieval with the ability to look up the answers, retrieval practice is a much better form of studying than the ones most students apply.

Is Difficulty Desirable?

What makes practicing retrieval so much better than review? One answer comes from the psychologist R. A. Bjork's concept of desirable difficulty.⁵ More difficult retrieval leads to better learning, provided the act of retrieval is itself successful. Free recall tests, in which students need to recall as much as they can remember without prompting, tend to result in better retention than cued recall tests, in which students are given hints about what they need to remember. Cued recall tests, in turn, are better than recognition tests, such as multiple-choice answers, where the correct answer needs to be recognized but not generated. Giving someone a test immediately after they learn something improves retention less than giving them a slight delay, long enough so that answers aren't in mind when they need them. Difficulty, far from being an obstacle to making retrieval work, may be part of the reason it does so. The idea of desirable difficulties in retrieval makes a potent case for the ultralearning strategy. Low-intensity learning strategies typically involve either less or easier retrieval. Pushing difficulty higher and opting for testing

oneself well before you are “ready” is more efficient. One can think back to Benny Lewis’s strategy of speaking a new language from the first day. Though this approach is high in difficulty, research suggests why it might be more useful than easier forms of classroom study. Placing himself in a more difficult context means that every time Lewis needs to recall a word or phrase, it will be remembered more strongly than when doing the same act of retrieval in a classroom setting and much better than when simply looking over a list of words and phrases.

Difficulty can become undesirable if it gets so hard that retrieval becomes impossible. Delaying the first test of a newly learned fact has some benefits over testing immediately.⁶ However, if you delay the test too long, the information may be forgotten entirely.⁷ The idea, therefore, is to find the right midpoint: far enough away to make whatever is retrieved remembered deeply, not so far away that you’ve forgotten everything. Although waiting too long before you test yourself may have disadvantages, increasing difficulty by giving yourself fewer clues and prompts are likely helpful, provided that you can get some feedback on them later.

Should You Take the Final Exam Before the Class Even Begins?

The standard way of viewing tests is that they work to evaluate the knowledge you have learned elsewhere—through reading or listening to lectures. The concept of retrieval flips this view on its head, suggesting that the act of taking a test not only is a source of learning but results in more learning than a similar amount of time spent in review. However, this still fits within the conventional idea of knowledge being first acquired, and then strengthened or tested later.

An interesting observation from retrieval research, known as the forward-testing effect, shows that retrieval not only helps enhance what you’ve learned previously but can even help prepare you to learn better.⁸ Regular testing of previously studied information can make it easier to learn new information. This means that retrieval works to enhance future learning, even when there is nothing to retrieve yet!

A variety of mechanisms has been proposed for explaining why this forward testing effect exists. Some researchers argue that it may be that trying to find knowledge that hasn’t been learned yet—say, by trying to solve a problem you haven’t learned the answer to yet—nonetheless helps reinforce search strategies that are put to use once the knowledge is encountered later.

An analogy here is that trying to retrieve an answer that doesn’t yet exist in your mind is like laying down a road leading to a building that hasn’t been constructed yet. The destination doesn’t exist, but the path to get to where it will be, once constructed, is developed regardless. Other researchers argue that the mechanism might be one of attention. By confronting a problem you don’t yet know how to answer, your mind automatically adjusts its attentional resources to spot information that looks like a solution when you learn it later. Whatever the exact mechanism is, the reality of the forward-testing effect implies that practicing retrieval might not only benefit from starting earlier than one is “ready” but even before you have the possibility of answering correctly.

What Should Be Retrieved?

The research is clear: if you need to recall something later, you’re best off practicing retrieving it. However, this neglects an important question: What kinds of things should you invest the time in to remember in the first place?

Retrieval may take less time than review to get the same learning impact, but not learning something at all is faster still. This is an important practical question. Nobody has time to master everything. During the MIT Challenge, I covered a lot of different ideas. Some were directly relevant to the kind of programming I wanted to do when I was done, so making sure I retained those ideas was a priority. Others were interesting, but since I had no plans to use them immediately, I put more effort into practicing retrieving the underlying concepts than doing technical calculations. One class I did, for instance, was Modal Logic. As I have no plans to be a logician, I can honestly say, eight years later, that I couldn't prove theorems in modal logic today. However, I can tell you what modal logic is for and when it is used, so if a situation arises in which the techniques I learned in that class might be useful, I'd have a much better time spotting it.* There will always be some things you choose to master and others you satisfy yourself with knowing you can look up if you need to.

One way to answer this question is simply to do direct practice. Directness sidesteps this question by forcing you to retrieve the things that come up often in the course of using the skill. If you're learning a language and need to recall a word, you'll practice it. If you never need a word, you won't memorize it. The advantage of this strategy is that it automatically leads you to learn the things with the highest frequency. Things that are rarely used or that are easier to look up than to memorize won't be retrieved. These tend to be the things that don't matter so much.

The problem with relying on direct practice exclusively is that knowledge that isn't in your head can't be used to help you solve problems. For instance, a programmer may realize a need to use a certain function to solve a problem but forgets how to write it out. Needing to look up the syntax might slow her down, but she will still be able to solve the problem. However, if you don't have enough knowledge stored to recognize when you can use a function to solve your problem, no looking up can help you. Consider that over the last twenty years, the amount of knowledge easily accessible from a quick online search has exploded. Nearly any fact or concept is now available on demand to anyone with a smartphone. Yet despite this incredible advance, it is not as if the average person is thousands as times as smart as people were a generation ago. Being able to look things up is certainly an advantage, but without a certain amount of knowledge inside your head, it doesn't help you solve hard problems.

Direct practice alone can fail to encourage enough retrieval by omitting knowledge that can help you solve a problem but isn't strictly necessary to do so. Consider our programmer who has two different ways to solve her problem, A and B. Option A is much more effective, but B will also get the job done. Now suppose that she knows only about option B. She'll continue to use the way she knows to solve the problem, even though it is less effective. Here, our fledgling programmer might read about option A on a blog somewhere. But since simply reading is much less effective than repeated retrieval practice, chances are that she'll forget about it when it comes time to apply the technique. This may sound abstract, but I'd argue that this is quite common with programmers, and often the thing separating mediocre programmers from great ones isn't the range of problems they can solve but that the latter often know dozens of ways to solve problems and can select the best one for each situation. This kind of breadth requires a certain amount of passive exposure, which in turn benefits from retrieval practice.

How to Practice Retrieval

Retrieval works, but it isn't always easy. Not only is the effort itself an obstacle, but sometimes it's not clear exactly how to do it. Passive review may not be very efficient, but at least it's straightforward: you open your book and reread material until you retain it. Most books and resources don't have a handy list of questions at the end to test you to see if you remember what they contain. To help with that, below are some useful methods that can be used to apply retrieval to almost any subject.

Tactic 1: Flash Cards

Flash cards are an amazingly simple, yet effective, way to learn paired associations between questions and answers. The old way of creating paper flash cards to drill yourself is powerful, but it has largely been superseded by spaced-repetition systems, as I'll discuss in Principle 7. These software algorithms can handle tens of thousands of "cards" and also organize a review schedule so you can manage them.

The major drawback of flash cards is that they work really well for a specific type of retrieval—when there's a pairing between a specific cue and a particular response. For some forms of knowledge, for example memorizing foreign-language vocabulary, this works perfectly. Similarly, maps, anatomical diagrams, definitions, and equations can often be memorized via flash cards. However, when the situation in which you need to remember the information is highly variable, this kind of practice can have drawbacks. Programmers can memorize syntax via flash cards, but concepts that need to be applied in real programs often don't fit the cue-response framework that flash cards demand.

Tactic 2: Free Recall

A simple tactic for applying retrieval is, after reading a section from a book or sitting through a lecture, to try to write down everything you can remember on a blank piece of paper. Free recall like this is often very difficult, and there will be many things missed, even if you just finished reading the text in question. However, this difficulty is also a good reason why this practice is helpful. By forcing yourself to recall the main points and arguments, you'll be able to remember them better later. While doing research for this book, for instance, I would often print out journal articles and put them in a binder with a few blank sheets of paper after each of them. After I had finished reading, I'd do a quick free recall exercise to make sure I would retain the important details when it came time for writing.

Tactic 3: The Question-Book Method

Most students take notes by copying the main points as they encounter them. However, another strategy for taking notes is to rephrase what you've recorded as questions to be answered later. Instead of writing that the Magna Carta was signed in 1215, you could instead write the question "When was the Magna Carta signed?" with a reference to where to find the answer in case you forget. By taking notes as questions instead of answers, you generate the material to practice retrieval on later.

One mistake I've made in applying this technique is to focus on the wrong kinds of things to ask questions about. I tried applying this method to a book on computational neuroscience, and I ended up asking myself all sorts of detailed questions such as what was the firing rate of certain neuronal circuits or who proposed a specific theory. That wasn't intentional but rather a byproduct of lazily restating the factual content in the book as questions. What's harder and more useful is to restate the big idea of a chapter or section as a

question. Since this is often implicit, it requires some deeper thinking and not just adding a question mark to some notes you copied verbatim. One rule I've found helpful for this is to restrict myself to one question per section of a text, thus forcing myself to acknowledge and rephrase the main point rather than zoom in on a detail that will be largely irrelevant later.

Tactic 4: Self-Generated Challenges

The above tactics work best with retrieval of simple information, such as facts or summaries of broad ideas you might encounter in a book or lecture. However, if you're trying to practice a skill, not merely remember information, they might not be enough. For a programmer, it's not enough to know what an algorithm means, but be able to write it in code. In this case, as you go through your passive material, you can create challenges for yourself to solve later. You may encounter a new technique and then write a note to demonstrate that technique in an actual example. Creating a list of such challenges can serve as a prompt for mastering that information later in practice and can expand your library of tools that you are able to actually apply.

Tactic 5: Closed-Book Learning

Nearly any learning activity can become an opportunity for retrieval if you cut off the ability to search for hints. Concept mapping, the strategy that didn't work particularly well for students in Karpicke and Blunt's experiments, could be beefed up considerably by preventing yourself from looking at the book when generating your concept map. I suspect that had this been done in the original experiment, students using this form of closedbook concept mapping would likely have done better on the eventual test that relied on creating a concept map. Any practice, whether direct or a drill, can be cut off from the ability to look things up. By preventing yourself from consulting the source, the information becomes knowledge stored inside your head instead of inside a reference manual.

Revisiting Ramanujan

Ramanujan was smart, there's no denying it. However, his genius was aided immeasurably by two hallmarks of the ultralearner's tool kit: obsessive intensity and retrieval practice. As he worked on his slate from morning to night, trying to figure out Carr's sparsely written list of theorems was incredibly hard work. But it also created the desirable difficulties that allowed him to build a huge mental library of tools and tricks that would assist him in his later mathematical efforts.

Retrieval played an important role in Ramanujan's mathematical upbringing, but he is hardly the only one to take advantage of the tactic. In nearly every biography of great geniuses and contemporary ultralearners I have encountered, some form of retrieval practice is mentioned. Benjamin Franklin practiced his writing by reconstructing essays from memory. Mary Somerville worked through problems mentally when no candle was available for night reading. Roger Craig practiced trivia questions without looking at the answers. Retrieval is not a sufficient tool to create genius, but it may be a necessary one.

Trying to produce the answer rather than merely reviewing it is only half of a bigger cycle, however. To make retrieval really effective, it helps to know whether the answer you dredged up from your mind was correct. Just as we often avoid testing ourselves until we're ready because struggling with a test is uncomfortable, we often avoid seeking information about our skill level until we think it will be favorable. Being able to process that

information effectively, hearing the message it contains loud and clear, isn't always easy. Yet this is also why it is so important. This brings us to the next principle of ultralearning: feedback.

Chapter 9: Principle 6 Feedback: Don't Dodge the Punches

From a narrow staircase in the back, Chris Rock enters the stage just as his name is being announced. With sold-out shows and HBO specials, Rock is no neophyte to stand-up comedy. His performances feel like a rock concert. With an energetic and punctuated delivery, he's known for repeating the key phrase of a joke like the chorus of a song, the rhythm of it so precise that you get the feeling he would be able to make anything funny. And that's exactly the problem. When everything you do is funny, how do you know what really makes a joke good?

Far from the packed concert halls and jubilant crowds, Rock walks to the mic on the modest brick-backed stage at the Comedy Cellar in Greenwich Village, New York City. In his hand are scraps of cards on which he has scribbled bits of phrases, a trick for working out new material he learned from his grandfather, a cab driver who preached on weekends. Instead of his signature aggressive style, he slumps against the back wall. This is his laboratory, and he's going to perform comedy with the precision of an experiment.

"It's not going to be that good," Rock warns the crowd, who are stunned at his unannounced arrival on the small comedy stage. "Not at these prices," he adds, joking "At these prices, I could leave right now!" He envisions the reviews: "Chris came out and he left. It was good! He didn't tell any jokes—but it was good!" Notes in hand, Rock warns the audience playfully that this isn't going to be a typical Chris Rock performance. Instead, he wants to work out new material under controlled conditions. "They'll give you about six minutes because you're famous," he explains. "... then you're back to square one." He wants to know what's funny, when he's not trying to be funny.¹

Rock's method is not unique. The Comedy Cellar is famous for big-name drop-ins: Dave Chappelle, Jon Stewart, and Amy Schumer are just a few comedians who have tested out their material in front of small crowds here before performing it on prime-time specials and in concert-scale gigs. Why perform at a small club when you can easily draw large crowds and thousands of dollars from a huge performance? Why show up unannounced and then deliberately undersell your own comedic abilities? What Rock and these other famous comedians recognize is the importance of the sixth principle of ultralearning: feedback.

The Power of Information

Feedback is one of the most consistent aspects of the strategy ultralearners use. From the simple feedback of Roger Craig testing himself on Jeopardy! clues without knowing the answer to the uncomfortable feedback of Benny Lewis's approach of walking up to strangers to speak a language he only started learning the day prior, getting feedback was one of the most common tactics of the ultralearners I encountered. What often separated the ultralearning strategy from more conventional approaches was the immediacy, accuracy, and intensity of the feedback being provided. Tristan de Montebello could have taken the normal route of carefully preparing his script and then delivering a speech once every month or two, as is the case for most Toastmasters. Instead he dove straight in, speaking several times per week, jumping among different clubs to gather different perspectives on his performance. This deep dive into feedback was uncomfortable, but the rapid immersion also desensitized him to a lot of the anxiety that being onstage can create.

Feedback features prominently in the research on deliberate practice, a scientific theory of the acquisition of expertise initiated by K. Anders Ericsson and other psychologists. In his studies, Ericsson has found that the ability to gain immediate feedback on one's performance is an essential ingredient in reaching expert levels of performance. No feedback, and the result is often stagnation—long periods of time when you continue to use a skill but don't get any better at it. Sometimes the lack of feedback can even result in declining abilities. Many medical practitioners get worse with more experience as their accumulated knowledge from medical school begins to fade and the accuracy of their diagnoses is not given the rapid feedback that would normally promote further learning.²

Can Feedback Backfire?

The importance of feedback probably isn't too surprising; we all intuitively sense how getting information about what we're doing right and wrong can accelerate learning. More interestingly, the research on feedback shows that more isn't always better. Crucially, what matters is the type of feedback being given.

In a large meta-analysis, Avraham Kluger and Angelo DeNisi looked at hundreds of studies on the impact of providing feedback for learning.³

Though the overall effect of feedback was positive, it's important to note that in over 38 percent of cases, feedback actually had a negative impact. This leads to a confusing situation. On the one hand, feedback is essential for expert attainment, as demonstrated by the scientific studies of deliberate practice. Feedback also figures prominently in ultralearning projects, and it's difficult to imagine their being successful if their sources of feedback had been turned off. At the same time, a review of the evidence doesn't paint the picture of feedback being universally positive. What's the explanation?

Kluger and DeNisi argue that the discrepancy is in the type of feedback that is given. Feedback works well when it provides useful information that can guide future learning. If feedback tells you what you're doing wrong or how to fix it, it can be a potent tool. But feedback often backfires when it is aimed at a person's ego. Praise, a common type of feedback that teachers often use (and students enjoy), is usually harmful to further learning. When feedback steers into evaluations of you as an individual (e.g., "You're so smart!" or "You're lazy"), it usually has a negative impact on learning. Further, even feedback that includes useful information needs to be correctly processed as a motivator and tool for learning. Kluger and DeNisi noted that some of the studies that showed a negative impact of feedback occurred because the subjects themselves chose not to use the feedback constructively. They may have rejected the feedback, lowered the standards they expect from themselves, or given up on the learning task altogether. The researchers note that who is giving the feedback can matter, as feedback coming from a peer or teacher has important social dynamics beyond mere information on how to improve one's abilities.

I find two things interesting about this research. First, it is clear that although informative feedback is beneficial, it can backfire if it is processed inappropriately or if it fails to provide useful information. This means that when seeking feedback, the ultralearner needs to be on guard for two possibilities. The first is overreacting to feedback (both positive and negative) that doesn't offer specific information that leads to improvement.

Ultralearners need to be sensitive to what feedback is actually useful and tune out the rest. This is why, although all the ultralearners I met employed

feedback, they didn't act on every piece of possible feedback. Eric Barone, for instance, did not attend to every comment and critique on early drafts of his game. In many cases he ignored them, when the feedback conflicted with his vision. Second, when it is incorrectly applied, feedback can have a negative impact on motivation. Not only can overly negative feedback lower your motivation, but so can overly positive feedback. Ultralearners must balance both concerns, pushing for the right level of feedback for their current stage of learning. Though we all know (and instinctively avoid) harsh and unhelpful criticism, the research also supports Rock's strategy of disregarding the positive feedback that his celebrity automatically generates. The second interesting point about this research is that it explains why feedback-seeking efforts are often underused and thus remain a potent source of comparative advantage for ultralearners. Feedback is uncomfortable. It can be harsh and discouraging, and it doesn't always feel nice. Standing up on a stage in a comedy club to deliver jokes is probably one of the best ways to get better at stand-up comedy. But the act itself can be terrifying, as an awkward silence cuts deep. Similarly, speaking immediately in a new language can be painful, as the sense of your ability to communicate goes down precipitously from when you use your native tongue.

Fear of feedback often feels more uncomfortable than experiencing the feedback itself. As a result, it is not so much negative feedback on its own that can impede progress but the fear of hearing criticism that causes us to shut down. Sometimes the best action is just to dive straight into the hardest environment, since even if the feedback is very negative initially, it can reduce your fears of getting started on a project and allow you to adjust later if it proves too harsh to be helpful.

All of these acts require self-confidence, resolve, and persistence, which is why many self-directed learning efforts ignore seeking the aggressive feedback that could generate faster results. Instead of going to the source, taking feedback directly, and using that information to learn quickly, people often choose to dodge the punches and avoid a potentially huge source of learning. Ultralearners acquire skills quickly because they seek aggressive feedback when others opt for practice that includes weaker forms of feedback or no feedback at all.

What Kind of Feedback Do You Need?

Feedback shows up in many different forms for different types of learning projects. Getting good at stand-up comedy and learning to write computer programs involve very different kinds of feedback. Learning higher math and learning languages are going to use feedback in different ways. The opportunities for seeking better feedback will vary depending on what you're trying to learn. Rather than try to spell out exactly what feedback you need for your learning project, I think it's important to consider different types of feedback, along with how each one can be used and cultivated. By knowing what kind of feedback you're getting, you can make sure to use it best, while also recognizing its limitations. In particular, I want to consider three types of feedback: outcome feedback, informational feedback, and corrective feedback. Outcome feedback is the most common and in many situations the only type of feedback available. Informational feedback is also fairly common, and it's important to recognize when you can split apart outcomes to get feedback on parts of what you're learning and when feedback only on holistic outcomes is possible. Corrective feedback is the toughest to find but when employed well can accelerate learning the most.

Outcome Feedback: Are You Doing It Wrong?

The first type of feedback, and the least granular, is outcome feedback. This tells you something about how well you're doing overall but offers no ideas as to what you're doing better or worse. This kind of feedback can come in the form of a grade—pass/fail, A, B, or C—or it can come in the form of an aggregate feedback to many decisions you're making simultaneously. The applause Tristan de Montebello received (or the crickets he heard) after a speech is an example of outcome feedback. It could tell him if he was getting better or worse, but it couldn't really say why or how to fix it. Every entrepreneur experiences this kind of feedback when a new product hits the market. It may sell wildly well or abysmally, but that feedback comes in bulk, not directly decomposable into the various aspects of the product. Did the product cost too much? Was the marketing message not clear enough? Was the packaging unappealing? Customer reviews and comments can provide clues, but ultimately the success or failure of any new product is a complex bundle of factors.

This type of feedback is often the easiest to get, and research shows that even getting this feedback, which lacks a specific message about what you need to improve, can be helpful. In one study, feedback for a task involving visual acuity facilitated learning, even when it was delivered in blocks that were too large to get any meaningful information about which responses were correct and which were incorrect.⁴ Many projects that wholly lack feedback can easily be changed to get this broad-scale feedback. Eric Barone, for instance, provided a development blog to publish work on his game and solicit feedback from early drafts. It couldn't provide him with detailed information about what exactly to improve and change, but his simply being immersed in an environment that provided feedback at all was helpful. Outcome feedback can improve how you learn through a few different mechanisms. One is by providing you with a motivational benchmark against your goal. If your goal is to reach a certain quality of feedback, this feedback can give you updates on your progress. Another is that it can show you the relative merits of different methods you're trying. When you are progressing rapidly, you can stick to those learning methods and approaches. When progress stalls, you can see what you might be able to change in your current approach. Although outcome feedback isn't complete, it is often the only kind available and can still have a potent impact on your learning rate.

Informational Feedback: What Are You Doing Wrong?

The next type of feedback is informational feedback. This feedback tells you what you're doing wrong, but it doesn't necessarily tell you how to fix it. Speaking a foreign language with a native speaker who doesn't share a language with you is an exercise in informational feedback. That person's confused stare when you misuse a word won't tell you what the correct word is, but it will tell you that you're getting it wrong. Tristan de Montebello, in addition to the overall assessment of his performance by audience members at the end of a speech, can also get live informational feedback about how it's going moment to moment. Did that joke work? Is my story boring them? This is something you can spot in the distracted glances or background chatter throughout your speech. Rock's stand-up experiment is also a type of informational feedback. He can tell when a certain joke lands or doesn't, based on the reaction of the audience. However, they can't tell him what to do to make it funnier—he's the comedian, not them.

This kind of feedback is easy to obtain when you can get real-time access

to a feedback source. A computer programmer who gets error messages when her programs don't compile properly may not have enough knowledge to understand what she's doing wrong. But as errors increase or diminish, depending on what she does, she can use that signal to fix her problems. Self-provided feedback is also ubiquitous, and in some pursuits it can be almost as good as feedback from others. When painting a picture, you can simply look at it and get a sense of whether your brushstrokes are adding to or detracting from the image you want to convey. Because this kind of feedback often comes from direct interaction with the environment, it often pairs well with the third principle, directness.

Corrective Feedback: How Can You Fix What You're Doing Wrong?

The best kind of feedback to get is corrective feedback. This is the feedback that shows you not only what you're doing wrong but how to fix it. This kind of feedback is often available only through a coach, mentor, or teacher. However, sometimes it can be provided automatically if you are using the right study materials. During the MIT Challenge, I did most of my practice by going back and forth between assignments and their solutions, so that when I finished a problem, I was shown not only whether I had gotten it right or wrong but exactly how my answer differed from the correct one. Similarly, flash cards and other forms of active recall provide corrective feedback by showing you the answer to a question after you make your guess.

The educators Maria Araceli Ruiz-Primo and Susan M. Brookhart argue, "The best feedback is informative and usable by the student(s) who receive it. Optimal feedback indicates the difference between the current state and the desired learning state AND helps students to take a step to improve their learning."⁵

The main challenge of this kind of feedback is that it typically requires access to a teacher, expert, or mentor who can pinpoint your mistakes and correct them for you. However, sometimes the added edge of having corrective over merely informational feedback can be worth the effort needed to find such people. Tristan de Montebello worked with Michael Gendler to help him with his public speaking performance, and that helped him spot subtle weaknesses in his presentations that would have gone unnoticed by himself or by a less experienced audience member giving broader feedback. This type of feedback trumps outcome feedback, which can't indicate what needs improving, and informational feedback, which can indicate what to improve but not how. However, it can also be unreliable. Tristan de Montebello would often get conflicting advice after delivering a speech; some audience members would tell him to slow down, while others said to speed up. This can also be a situation in which paying for a tutor can be useful, because that person can spot the exact nature of your mistake and correct it with less struggle on your part. The self-directed nature of ultralearning shouldn't convince you that learning is best done as an entirely solitary pursuit.

Further Notes on Types of Feedback

A few things are worth noting here. First, you need to be careful when trying to "upgrade" feedback from a weaker form to a stronger form if it's not actually possible. To switch from outcome feedback to informational feedback, you need to be able to elicit feedback on a per element basis of what you're doing. If instead the feedback is being provided as a holistic assessment of everything you're doing, trying to turn it into informational

feedback can backfire. Game designers know to watch out for this, because asking play testers what they don't like about a game can often return spurious results: for example, they don't like the color of the character or the background music. The truth is, the players are evaluating the game holistically, so they often can't offer this kind of feedback. If their responses come from using it as a whole, not from each aspect individually, asking for greater specificity may lead to guesses from those giving feedback. Similarly, corrective feedback requires a "correct" answer or the response of a recognized expert. If there is no expert or a single correct approach, trying to turn informational feedback into corrective feedback can work against you when the wrong change is suggested as an improvement. De Montebello noted to me that the advice most people gave him wasn't terribly useful, but the consistency of it was. If his speech elicited wildly different reactions each time, he knew there was still a lot of work to do. When the speech started to get much more consistent comments, he knew he was onto something. This illustrates that ultralearning isn't simply about maximizing feedback but also knowing when to selectively ignore elements of it to extract the useful information. Understanding the merits of these different types of feedback, as well as the preconditions that make them possible, is a big part of choosing the right strategy for an ultralearning project.

How Quick Should Feedback Be?

An interesting question in the research on feedback is how quick it should be. Should you get immediate information about your mistakes or wait some period of time? In general, research has pointed to immediate feedback being superior in settings outside of the laboratory. James A. Kulik and Chen-Lin C. Kulik review the literature on feedback timing and suggest that "Applied studies using actual classroom quizzes and real learning materials have usually found immediate feedback to be more effective than delay."⁶ Expertise researcher K. Anders Ericsson agrees, arguing in favor of immediate feedback when it assists in identifying and correcting mistakes and when it allows one to execute a corrected version of their performance revised in response to the feedback.⁷

Interestingly, laboratory studies tend to show that delaying the presentation of the correct response along with the original task (delayed feedback) is more effective. The simplest explanation of this result is that presenting the question and answer again offers a second, spaced exposure to the information. If this explanation were correct, all it would mean is that that immediate feedback is best paired with delayed review (or further testing) to strengthen your memory compared with a single exposure. I'll cover more on spacing and how it impacts your memory in the next chapter on retention. Despite the superficially mixed results on the timing of feedback from the scientific literature, I generally recommend faster feedback. This enables a quicker recognition of mistakes. However, there's a possible risk that this recommendation might backslide into getting feedback before you've tried your best to answer the question or solve the problem at hand. Early studies on feedback timing tended to show a neutral or negative impact of immediate feedback on learning. In those studies, however, experimenters often gave subjects the ability to see the correct answer before subjects had finished filling out the prompt.⁸ That meant subjects could often copy the correct answer rather than try to retrieve it. Feedback too soon may turn your retrieval practice effectively into passive review, which we already know is less effective for learning. For hard problems, I suggest setting yourself a

timer to encourage you to think hard on difficult problems before giving up to look at the correct answer.

How to Improve Your Feedback

By now you see the importance of feedback to your learning efforts. I've explained why feedback, especially when delivered to others, can sometimes backfire. I've also showed how the three types—outcome, informational, and corrective—have different strengths and the preconditions that need to be in place in order to make them effective. Now I want to focus on some concrete tactics you can apply to get better feedback.

Tactic 1: Noise Cancellation

Anytime you receive feedback, there are going to be both a signal—the useful information you want to process—and noise. Noise is caused by random factors, which you shouldn't overreact to when trying to improve. Say you're writing articles that you post online, trying to improve your writing ability. Most of them won't attract much attention, and when they do, it's often because of factors outside of your control; for example, just the right person happens to share it, causing it to spill across social networks. The quality of your writing does drive these factors, but there's enough randomness that you need to be careful not to change your entire approach based on one data point. Noise is a real problem when trying to improve your craft because you need to do far more work to get the same information about how to write well. By modifying and selecting the streams of feedback you pay attention to, you can reduce the noise and get more of the signal.

A noise-cancelling technique used in audio processing is filtering. Sound engineers know that human speech tends to fall within a particular range of frequencies, whereas white noise is all over the spectrum. They can boost the signal, therefore, by amplifying the frequencies that occur in human speech and quieting everything else. One way to do this is to look for proxy signals. These don't exactly equal success, but they tend to eliminate some of the noisy data. For blog writing, one way to do so would be to use tracking code to figure out what percentage of people read your articles all the way to the end. This doesn't prove your writing is good, but it's a lot less noisy than raw traffic data.

Tactic 2: Hitting the Difficulty Sweet Spot

Feedback is information. More information equals more opportunities to learn. A scientific measure of information is based on how easily you can predict what message it will contain. If you know that success is guaranteed, the feedback itself provides no information; you knew it would go well all along. Good feedback does the opposite. It is very hard to predict and thus gives more information each time you receive it.

The main way this impacts your learning is through the difficulty you're facing. Many people intuitively avoid constant failure, because the feedback it offers isn't always helpful. However, the opposite problem, of being too successful, is more pervasive. Ultralearners carefully adjust their environment so that they're not able to predict whether they'll succeed or fail. If they fail too often, they simplify the problem so they can start noticing when they're doing things right. If they fail too little, they'll make the task harder or their standards stricter so that they can distinguish the success of different approaches. Basically, you should try to avoid situations that always make you feel good (or bad) about your performance.

Tactic 3: Metafeedback

Typical feedback is performance assessment: your grade on a quiz tells you

something about how well you know the material. However, there's another type of feedback that's perhaps even more useful: metafeedback. This kind of feedback isn't about your performance but about evaluating the overall success of the strategy you're using to learn.

One important type of metafeedback is your learning rate. This gives you information about how fast you're learning, or at least how fast you're improving in one aspect of your skill. Chess players might track their Elo ratings growth. LSAT studiers might track their improvements on mock exams. Language learners might track vocabulary learned or errors made when writing or speaking. There are two ways you can use this tool. One is to decide when you should focus on the strategy you're already using and when you should experiment with other methods. If your learning rate is slowing to a trickle, that might mean you're hitting diminishing returns with your current approach and could benefit from different kinds of drills, difficulties, or environments. A second way you can apply metafeedback is by comparing two different study methods to see which works better. During the MIT Challenge, I'd often split up questions from different subtopics before testing myself on an exam and try different approaches side by side. Does it work better to dive straight into trying to answer questions or to spend a little time to try to see that you understand the main concepts first? The only way you can know is to test your own learning rates.

Tactic 4: High-Intensity, Rapid Feedback

Sometimes the easiest way to improve feedback is simply to get a lot more of it a lot more often. This is particularly true when the default mode of learning involves little or infrequent feedback. De Montebello's strategy of improving public speaking relied largely on getting far more frequent exposure to the stage than most speakers do. Lewis's language immersion exposes him to information about his pronunciation at a point when most students still haven't uttered a word. High-intensity, rapid feedback offers informational advantages, but more often the advantage is emotional, too. Fear of receiving feedback can often hold you back more than anything. By throwing yourself into a high-intensity, rapid feedback situation, you may initially feel uncomfortable, but you'll get over that initial aversion much faster than if you wait months or years before getting feedback.

Being in such a situation also provokes you to engage in learning more aggressively than you might otherwise. Knowing that your work will be evaluated is an incredible motivator to do your best. This motivational angle for committing to high-intensity feedback may end up outweighing the informational advantage it provides.

Beyond Feedback

Receiving feedback isn't always easy. If you process it as a message about your ego rather than your skills, it's easy to let a punch become a knockout. Though carefully controlling the feedback environment so it is maximally encouraging may be a tantalizing option, real life rarely affords such an opportunity. Instead, it's better to get in and take the punches early so that they don't put you down for the count. Though short-term feedback can be stressful, once you get into the habit of receiving it, it becomes easier to process without overreacting emotionally. Ultralearners use this to their advantage, exposing themselves to massive amounts of feedback so that the noise can be stripped away from the signal.

Feedback and the information it provides, however, is useful only if you remember the lessons it teaches. Forgetting is human nature, so it is not

enough to learn; you also need to make the information stick. This brings us to the next principle of ultralearning, retention, in which we'll discuss strategies that will ensure the lessons you learn aren't forgotten.

Chapter 10- Principle 7: Retention: Don't Fill A Leaky Bucket

In the small Belgian city of Louvain-la-Neuve, Nigel Richards has just won the World Scrabble Championships. On its own, this isn't too surprising. Richards has won a championship three times before, and both his prowess with the game and his mysterious personality have made him something of a legend in competitive Scrabble circles. This time, however, is different: instead of the original English-language version of the famous crossword game, Richards has won the French World Championship. This is a much harder feat: most English dictionary versions have roughly 200,000 valid word entries; French, with its gendered nouns and adjectives and copious conjugations, has nearly double that with around 386,000 valid word forms.¹ To pull off such a feat is quite remarkable, even more so due to one simple fact: Richards doesn't speak French.

Richards, an engineer born and raised in Christchurch, New Zealand, is an unusual character. With his long beard and retro aviator sunglasses, he looks like a cross between Gandalf and Napoleon Dynamite. His skills at Scrabble, however, are no joke. A late starter to the game, his mother encouraged him to start in his late twenties, saying "Nigel, since you're no good at words, you won't be good at this game, but it will keep you occupied."² From those inauspicious beginnings Richards has gone on to dominate the competitive Scrabble scene. Some people even argue that he may be the greatest player of all time.

In case you've been living under a rock, Scrabble is based on forming crosswords. Each player has seven letter tiles, drawn from a bag, with which to form words. The catch is that the words must link up with the words already on the board. To be a good player requires a voluminous memory, not only of the words we use every day but of obscure words that are useful because of their length or the letters they contain. A decent casual player quickly learns all the valid two-letter words, including unusual ones such as "AA" (a type of lava) and "OE" (a windstorm in the Faroe Islands). To perform at tournament level, however, requires memorizing nearly all of the short words, as well as longer seven- and eight-letter words, since if a player uses up all seven tiles in one turn, there is an extra fifty-point bonus (or "bingo," in Scrabble jargon). Memory, however, isn't the only skill needed. Like other competitive games, tournament Scrabble uses a timing system, so skilled players must not only be able to construct valid words from a scrambled set of tiles but quickly find spaces and calculate which words will score the most points. In this regard, Richards is a master: given the tiles CDHLRN and one blank (which can be used for any letter), Richards ignored the obvious CHILDREN and instead linked up multiple crosswords to make the even higher scoring CHLORODYNE.

Richards's virtuosity is only intensified by the mystery that surrounds it. He is quiet and mostly keeps to himself. He refuses all interviews with reporters and seems completely uninterested in fame, fortune, or even providing explanations for how he does it. A fellow competitor, Bob Felt, bumping into Richards at a tournament noted his monklike serenity, telling him "When I see you, I can never tell whether you've won or lost." "That's because I don't care" was Richard's monotone response.³ Even his competing in Belgium, which briefly pulled him into the international media spotlight, was done as an excuse to do a cycling trip through Europe. In fact, prior to his victory, he had spent only nine weeks preparing. After he beat a

Francophone player, Schelick Ilagou Rekawe from Gabon, in the final match, he was given a standing ovation but needed a translator to thank the audience. What Is Nigel Richards's Secret?

The more I read about Nigel Richards, the more intrigued I became. Richards was as mysterious as he was incredible in his mnemonic abilities. He steadfastly ignores opportunities for interviews and is famously laconic in descriptions of his methods. After his victory in Louvain-la-Neuve, one reporter asked him if he had any special methods for memorizing all those words. "No" was Richards's monosyllabic response. Still, even if he wouldn't divulge his strategies publicly, perhaps some digging could reveal clues.

The first thing I discovered was that although Richards's victory in Belgium was astounding, it wasn't entirely without precedent. Other players of the game have won World Championships without being fluent in the language of competition. Scrabble is particularly popular in Thailand, for instance, and two former world champions, Panupol Sujjayakorn and Pakorn Nemitrmansuk, are not fluent in English. The reason is simple: remembering words in one's native language and remembering words in Scrabble are different mnemonic feats. In spoken language, the meaning of a word, its pronunciation, and its feel are important. In Scrabble, those things don't matter; words are just combinations of letters. Richards could win at French Scrabble without speaking French because the game wasn't much different from English; he just had to memorize different patterns of letters. A native speaker has an advantage, of course, since many spellings will already be familiar. But there will still be a large number of arcane and unfamiliar words to memorize, and the skill of rearranging the letters into valid board positions and calculating to achieve maximal points remains the same in every language in which Scrabble can be played.

The next piece of the puzzle I discovered was that Scrabble, it turns out, isn't the only activity in which Richards possesses a strange intensity. His other love is cycling. Indeed, in an early tournament in Dunedin, New Zealand, he got onto his bicycle after work finished, pedaled through the night from Christchurch to Dunedin, a distance of over two hundred miles, without sleeping, and started the tournament first thing in the morning. After he won, competitors he met at the tournament offered to give him a ride home. He politely declined, preferring to bicycle back the entire way home to Christchurch for another sleepless night before starting work again Monday morning.⁴ At first that felt like just another odd quirk in his profile, like his home-done haircuts and reluctance to be interviewed. Now, though, I believe it may hold some keys to unlocking some of his mystery.

Cycling, of course, isn't a great mnemonic technique. If it were, Lance Armstrong would have been a fierce contender. However, it does illustrate a common theme in Richards's personality that overlaps with that of other ultralearners I have encountered: an obsessive intensity that exceeds what is considered a normal investment of effort. Richards's cycling, it turns out, also lines up well with the only other clues I've been able to uncover about his methods: he reads lists; long lists of words, starting with two-letter words and then moving up. "The cycling helps," he explains, "I can go through lists in my mind."⁵ He reads the dictionary, focusing exclusively on combinations of letters, ignoring definitions, tenses, and plurals. Then, drawing from memory, he repeats them over and over again as he cycles for hours. This aspect also corresponds with a method that is common to other ultralearners

and that has shown up in other principles of learning so far: active recall and rehearsal. By retrieving words, Richards likely takes his already impressive memory and makes it unassailable through active practice.

There are other clues about Richards's performance: he focuses on memory, not anagramming (rearranging the tiles to create words); he works forward and backward, starting from small words, going on to big ones and back again; he claims to recall the words visually, as he cannot remember words when they're spoken. All of these clues provide glimpses into Richards's mind, but they leave out even more than they reveal. How many times does he have to read the words from his list before he can rehearse it mentally? Are the words organized in some way or just listed alphabetically? Is he a savant with exceptional abilities and lower-than-normal general intelligence or an all-round genius for whom memorizing Scrabble words is just one of many impressive abilities? Maybe his intelligence is quite average and his dominance in Scrabble represents his extreme dedication to the game. We might never know the answers to those questions.

I certainly can't rule out the theory that Richards's mind is simply hardwired differently or better for memory than my own. After all, nothing I've encountered so far about his method is so boldly original that serious Scrabble players would be unaware of it. Yet Richards has completely dominated his competition. Part of me suspects that his intense, obsessive personality, which enables him to cycle for hours reviewing lists mentally, might also form at least a partial explanation. Whatever gifts he might possess, he also seems to possess the ultralearner ethos I've described thus far in the book. For whatever it is worth, Richards himself argues for more of the latter than the former: "It's hard work, you have to have dedication to learn,"⁶ elsewhere adding "I'm not sure there is a secret, it's just a matter of learning the words."⁷

Scrabble words may not be important to your life. However, memory is essential to learning things well. Programmers must remember the syntax for the commands in their code. Accountants need to memorize ratios, rules, and regulations. Lawyers must remember precedents and statutes. Doctors need to know tens of thousands of factoids, from anatomical descriptions to drug interactions. Memory is essential, even when it is wrapped up in bigger ideas such as understanding, intuition, or practical skill. Being able to understand how something works or how to perform a particular technique is useless if you cannot recall it. Retention depends on employing strategies so the things you learn don't leak out of your mind. Before discussing strategies of retention, however, let's take a look at why remembering things is so difficult.

Why Is It So Hard to Remember Things?

Richards is an extreme case, but his story nonetheless illustrates many themes that are important for anyone who wants to learn something: How can you retain all of the things you learn? How can you defend against forgetting hard-won facts and skills? How can you store the knowledge you've acquired so that it can be easily retrieved exactly when you need it? In order to understand learning, you need to understand how and why you forget. Losing access to previously learned knowledge has been a perennial problem for educators, students, and psychologists. Fading knowledge impacts the work you do as well. One study reported that doctors give worse medical care the longer they have worked, as their stored knowledge from medical school is gradually forgotten, despite their working in the profession

full-time. Quoting from the original abstract:

Physicians with more experience are generally believed to have accumulated knowledge and

skills during years in practice and therefore to deliver high-quality care. However, evidence suggests that there is an inverse relationship between the number of years that a physician has

been in practice and the quality of care that the physician provides.⁸

Hermann Ebbinghaus, in one of the first psychological experiments in history, spent years memorizing nonsense syllables, much in the same way

Richards memorizes Scrabble words, and carefully tracking his ability to recall them later. From this original research, later verified by more

experimentally robust studies, Ebbinghaus discovered the forgetting curve.

This curve shows that we tend to forget things incredibly quickly after learning them, there being an exponential decay in knowledge, which is steepest right after learning. However, Ebbinghaus noted, this forgetting tapers off, and the amount of knowledge forgotten lessens over time. Our minds are a leaky bucket; however, most of the holes are near the top, so the water that remains at the bottom leaks out more slowly.

Over the intervening years, psychologists have identified at least three dominant theories to help explain why our brains forget much of what we initially learn: decay, interference, and forgotten cues. Though the jury is still out on the exact mechanism underlying human long-term memory, these three ideas likely form some part of explaining why we tend to forget things and, conversely, provide insight into how we might better retain what we've learned.

Decay: Forgetting with Time

The first theory of forgetting is that memories simply decay with time. This idea does seem to match common sense. We remember events, news, and things learned in the past week much more clearly than things from last month. Things learned this year are recalled with much greater accuracy than events from a decade ago. By this understanding, forgetting is simply an inevitable erosion by time. Like sands in an hourglass, our memories inexorably slip away from us as we become more distant from them.

There are flaws with this theory being the complete explanation, however.

Many of us can vividly recall events from early childhood, even if we can't remember what we ate for breakfast last Tuesday. There also seem to be patterns in which things are remembered and which are forgotten that go beyond the time since they were originally learned: vivid, meaningful things are more easily recalled than banal or arbitrary information. Even if there is a component to our forgetting that is simply decay, it seems exceedingly unlikely that this is the only factor.

Interference: Overwriting Old Memories with New Ones

Interference suggests a different idea: that our memories, unlike the files of a computer, overlap one another in how they are stored in the brain. In this way, memories that are similar but distinct can compete with one another. If you're learning programming, for instance, you may learn what a for loop is and remember it in terms of doing something repeatedly. Later, you may learn about while loops, recursion, repeat-until loops, and go-to statements. Now, each of these has to do with doing something repeatedly, but in different ways, so they may interfere with your ability to remember correctly what a for loop does. There are at least two flavors of this: proactive

interference and retroactive interference. Proactive interference occurs when previously learned information makes acquiring new knowledge harder. Think of this as if the “space” where that information wants to be stored is already occupied, so forming the new memory becomes harder. This can happen when you want to learn the definition of a word but have difficulty because that word already has a different association in your mind. Consider trying to learn the concept of negative reinforcement in psychology—here the word “negative” has the meaning “absent,” as opposed to “bad,” so negative reinforcement is when you encourage a behavior by removing something, say a painful stimulus. However, since the earlier meaning of negative as “bad” already exists, you may have difficulty remembering this and it becomes easy to incorrectly equate negative reinforcement with punishment. Retroactive interference is the opposite—where learning something new “erases” or suppresses an old memory. Anyone who has learned Spanish and later tried to learn French knows how tricky retroactive interference can be, as French words pop out when you want to speak Spanish again.

Forgotten Cues: A Locked Box with No Key

The third theory of forgetting says that many memories we have aren't actually forgotten but simply inaccessible. The idea here is that in order to say that one has remembered something, it needs to be retrieved from memory. Since we aren't constantly experiencing the entirety of our longterm memories simultaneously, this means there must be some process for dredging up the information, given an appropriate cue. What may happen in this case is that one of the links in the chain of retrieving the information has been severed (perhaps by decay or interference) and therefore the entire memory has become inaccessible. However, if that cue were restored, or if an alternative path to the information could be found, we would remember much more than is currently accessible to us.

This explanation also has some advantages. Intuitively it seems to be somewhat true, as we all know the tip-of-the-tongue experience, when we feel as though we should be able to remember a fact or word but we're not able to summon it up immediately. It might also suggest that relearning things is much faster than learning them initially, because relearning is closer to repair work, while original learning is a completely new construction.

Forgetting cues seems highly likely as a partial, if not complete, explanation of forgetting many things.

Cue forgetting as a complete explanation for our memory woes isn't without its problems, however. Many memory researchers now believe that the act of remembering is not a passive process. In recalling facts, events, or knowledge, we're engaging in a creative process of reconstruction. The memories themselves are often modified, enhanced, or manipulated in the process of remembering. It may be, then, that “lost” memories that are retrieved through new cues are actually fabrications. This seems especially likely in the case of “recovered” witness testimony from traumatic events, as experiments have shown that even highly vivid memories that feel completely authentic to the subject can be untrue.⁹

How Can You Prevent Forgetting?

Forgetting is the default, not the exception, so the ultralearners I encountered had devised various strategies for coping with this fact of life. These methods roughly divide into tackling two similar but different problems. The first set of methods deals with the problem of retention while undertaking the ultralearning project: How can you retain the things you learned the first

week, so that you don't need to relearn them by the last week? This is particularly important for memory-intensive ultralearning efforts such as Benny Lewis's language learning and Roger Craig's Jeopardy! trivia mastery. In these domains and many others, the volume of information to be learned is often so large that the forgetting becomes a practical obstacle almost immediately. The second set of methods, in contrast, has to do with the longevity of the skills and knowledge acquired after the project has been completed: Once a language has been learned to a level you're satisfied with, how can you keep yourself from forgetting it completely a couple years later? The ultralearners I encountered had devised differing methods for dealing with these two problems, which varied in effort and intensity. Some, like Craig, preferred elaborate electronic systems that can optimize memory with fancy algorithms, leaving little waste and inefficiency, if at the cost of introducing greater complexity. Others, like Richards, seem to prefer basic systems that succeed on their simplicity.

You need to pick a mnemonic system, which will both accomplish your goals and be simple enough to stick to. During intense periods of language learning, the sheer volume of vocabulary often meant that spaced-repetition systems were helpful for me. Other times, I preferred having conversations to maintain my speaking ability, even though this method is not quite as precise. With other subjects, I'm happier to allow for some degree of forgetting as long as I practice the skills I need to use continuously and have the ability to relearn.

My approaches may not reach a theoretical ideal, but they may end up working better because they have fewer possibilities for error and can be sustained more easily. Regardless of the exact system used, however, all systems seemed to work according to one of four mechanisms: spacing, proceduralization, overlearning, or mnemonics. Let's look at each of these mechanisms of retention first, in order to make sense of the quite different and idiosyncratic manifestations used in different ultralearning projects.

Memory Mechanism 1—Spacing: Repeat to Remember

One of the pieces of studying advice that is best supported by research is that if you care about long-term retention, don't cram. Spreading learning sessions over more intervals over longer periods of time tends to cause somewhat lower performance in the short run (because there is a chance for forgetting between intervals) but much better performance in the long run. This was something I needed to be careful about during the MIT Challenge. After my first few classes, I switched from doing one class at a time to doing a few in parallel, to minimize the impact that the crammed study time would have on my memory.

If you have ten hours to learn something, therefore, it makes more sense to spend ten days studying one hour each than to spend ten hours studying in one burst. Obviously, however, if the amount of time between study intervals gets longer and longer, the short-term effects start to outweigh the long-term ones. If you learn something with a decade separating study intervals, it's quite possible that you'll completely forget whatever you had learned before you reach the second session.

Finding the exact trade-off point between too long and too short has been a minor obsession for some ultralearners. Space your study sessions too closely, and you lose efficiency; space them too far apart, and you forget what you've already learned. This has led many ultralearners to apply what are known as spaced-repetition systems (SRS) as a tool for trying to retain the

most knowledge with the least effort. SRS was a major force behind Roger Craig's Jeopardy! trivia memorization, and I used the systems extensively when learning Chinese and Korean. Although you may not have heard of this term, the general principle is the backbone of many language-learning products, including Pimsleur, Memrise, and Duolingo. These programs tend to hide the spacing algorithm in the background, so you don't need to bother yourself with it. However, other programs, such as the open-source Anki, are the preferred tool of more extreme ultralearners who want to squeeze out a little more performance.

SRS is an amazing tool, but it tends to have quite focused applications. Learning facts, trivia, vocabulary words, or definitions is ideally suited for flash card software, which presents knowledge in terms of a question with a single answer. It's more difficult to apply to more complicated domains of knowledge, which rely on complex information associations that are built up only through real-world practice. Still, for some tasks, the bottleneck of memory is so tight that SRS is a powerful tool for widening it, even if there are some drawbacks. The authors of a popular study guide for medical students center their approach around SRS, because a medical student must remember so many things and the default strategy of forgetting and relearning is quite costly in terms of time.¹⁰

Spacing does not require complex software, however. As Richards's story clearly demonstrates, simply printing lists of words, reading them over, and then rehearsing them mentally without having them in front of you is an incredibly powerful technique. Similarly, semiregular practice of a skill is often quite helpful. After my year of learning languages, I wanted to ensure that I didn't forget them. My approach was fairly simple: schedule thirty minutes of conversation practice once a week, to be done over Skype using italki, an online service for tutoring and language exchange partners all over the world. I maintained this for one year, after which I dropped to once-permonth practice for another two years. I don't know whether this practice schedule was ideal, and I had other opportunities to practice that came up spontaneously in that time period that also helped, but I believe it was much better than doing nothing and letting the skills atrophy. When it comes to retention, don't let perfect become the enemy of good enough.

Another strategy for applying spacing, which can work better for more elaborate skills that are harder to integrate into your daily habits, is to semiregularly do refresher projects. I leaned toward this approach for the things I learned during the MIT Challenge, since the skill I wanted most to retain was writing code, which is tricky to do on only half an hour per week. This approach has the disadvantage of sometimes deviating quite a lot from optimal spacing; however, if you're prepared to do a little bit of relearning to compensate, it can still be a better approach than completely giving up practice. Scheduling this kind of maintenance in advance can also be helpful, as it will remind you that learning isn't something done once and then ignored but a process that continues for your entire life.

Memory Mechanism 2—Proceduralization: Automatic Will Endure

Why do people say it's "like riding a bicycle" and not "like remembering trigonometry?" This common expression may be rooted in deeper neurological realities than it first appears. There's evidence that procedural skills, such as riding a bicycle, are stored in a different way from declarative knowledge, such as knowing the Pythagorean Theorem or the Sine Rule for

triangles. This difference between knowing how and knowing that may also have different implications for long-term memory. Procedural skills, such as the ever-remembered bicycling, are much less susceptible to being forgotten than knowledge that requires explicit recall to retrieve.¹¹

This finding can actually be used to our advantage. One dominant theory of learning suggests that most skills proceed through stages—starting declarative but ending up procedural as you practice more. A perfect example of this declarative-to-procedural transition is typewriting. When you start typing on a keyboard, you must memorize the positions of the letters. Each time you want to type a word, you have to think in terms of its letters, recall each one's position on the keyboard, and then move your finger to that spot to press it. This process may fail; you may forget where a key is and need to look down to type it. However, if you practice more and more, you stop having to look down. Eventually you stop having to think about the letters' positions or how to move your fingers to meet them. You may even reach a point where you don't think of letters at all and whole words come out at a time. Such procedural knowledge is quite robust and tends to be retained much longer than declarative knowledge. A quick observation is enough to verify this: when you've gotten really good at typing and someone asks you to quickly say where on a keyboard the letter w is, you might need to actually put your hands in the keyboard position (or imagine you're doing so) and pretend to type the w to say definitively. This is exactly what happened to me as I was typing out this paragraph. What has happened is that what was originally the primary access point to knowledge, your explicit memory of the key location, has faded away and now needs to be recalled with the more durable procedural knowledge encoded in your motor movements. If you've ever had to enter a password or pin code you use often, you may be in a similar position, where you remember it by feel and not by its explicit combination of numbers and letters.

Because of the fact that procedural knowledge is stored for longer, this may suggest a useful heuristic. Instead of learning a large volume of knowledge or skills evenly, you may emphasize a core set of information much more frequently, so that it becomes procedural and is stored far longer. This was an unintentional side effect of my friend's and my language learning project. Being forced to speak a language constantly meant that a core set of phrases and patterns was repeated so often that neither of us will ever forget them. This may not hold true for a bunch of less frequently used words or phrases, but the starting points of conversations are nearly impossible to forget. The classic approach to language studies, in which students "move on" from beginner words and grammatical patterns to more complicated ones may sidestep this, so that those core patterns aren't sticky enough to last for years without repeated practice.

Failing to fully proceduralize core skills was a major flaw of my first major self-education effort, the MIT Challenge, which I was able to improve upon in my subsequent language-learning and portrait-drawing projects. Whereas the MIT Challenge did have core mathematical and programming skills that were often repeated, what ended up being proceduralized was more haphazard rather than reflecting a conscious decision to automate the most essential skills of applying computer science.

Most skills we learn are incompletely proceduralized. We may be able to do some of them automatically, but other parts require us to actively search our minds. You might, for instance, be able to easily move variables from

one side of an equation to the other in algebra without thinking. But you may have to think a bit more when exponents or trigonometry is involved.

Perhaps, owing to their nature, some skills cannot be completely automated and will always require some conscious thought. This creates an interesting mix of knowledge, with some things retained quite stably over longer periods of time and others susceptible to being forgotten. One strategy for applying this concept might be to ensure that a certain amount of knowledge is completely proceduralized before practice concludes. Another approach might be to spend extra effort to proceduralize some skills, which will serve as cues or access points for other knowledge. You may aim to completely proceduralize the process you use to start working on a new programming project, for example, so that you can get over that hump in the process of writing a new program. These strategies are somewhat speculative, but I think there are lots of potential ways the declarative-to-procedural transition of knowledge might be applied by clever ultralearners in the future.

Memory Mechanism 3—Overlearning: Practice Beyond Perfect

Overlearning is a well-studied psychological phenomenon that's fairly easy to understand: additional practice, beyond what is required to perform adequately, can increase the length of time that memories are stored.¹² The typical experimental setup is to give subjects a task, such as assembling a rifle or going through an emergency checklist, allowing them enough time to practice that they can do it correctly once. The time from zero to this point is considered the “learning” phase. Next, allow the subjects different amounts of “overlearning,” or practice that continues after the first correct application. Since subjects are already doing the skill correctly, performance doesn't improve past this point. However, the overlearning can extend the durability of the skill.

In the typical setting in which overlearning has been studied, the duration of the overlearning effects tends to be quite short; practicing a little longer in one session produces an additional week or two of recall. This may imply that overlearning is primarily a short-term phenomenon: something useful for skills like first aid or emergency response protocols, which are rarely practiced but need to be kept fresh in between regular training sessions. I suspect, however, that overlearning might have longer-term implications if it is combined with spacing and proceduralization over much longer projects. In my own personal experience drawing portraits, for instance, the thought process used for mapping out the facial features I learned from Vitruvian Studio was repeated so many times that it's hard to forget, even though my major practice time was only during one month. Similarly, certain reflexes of programming or mathematics I can still easily recall from my MIT Challenge days, even without practice in the interim, because they happened to be patterns that were repeated far more than was necessary to perform them adequately at the time (because they were components of more elaborate problems).

Overlearning dovetails nicely with the principle of directness. Because direct use of a skill frequently involves overpracticing certain core abilities, that kernel is usually quite resistant to forgetting, even years later. In contrast, academically learned subjects tend to distribute practice more evenly to cover the entire curriculum to a minimum level of competency in each area, regardless of the centrality of subtopics to practical applications. Many people I've known who have learned a language that I also speak but who

learned it through years of formal schooling have much more impressive vocabularies or knowledge of grammatical nuances than I do. However, those same people may trip over fairly basic phrases, because they learned every fact and skill evenly, rather than overlearning the smaller subset of very common patterns.

There seem to be two main methods I've encountered for applying overlearning. The first is core practice, continually practicing and refining the core elements of a skill. This approach often works well paired with some kind of immersion or working on extensive (as opposed to intensive) projects, after the initial ultralearning phase has been completed. The shift from learning to doing here may actually involve a deeper, subtler form of learning, which shouldn't be discounted as simply applying previously learned knowledge.

The second strategy is advanced practice, going one level above a certain set of skills so that core parts of the lower-level skills are overlearned as one applies them in a more difficult domain. One study of algebra students demonstrated this second strategy.¹³ Most students who had taken an algebra class and were retested years later had forgotten huge amounts of what they had learned. This could have been either because the information was truly lost or simply because forgotten cues rendered the majority of it inaccessible. Interestingly, this rate of forgetting was the same for better- and poorer-performing students; better students retained more than weaker ones, but the rate at which they had forgotten was the same. One group, however, did not show such a steep decline in forgetting: those who had taken calculus. This suggests that moving up a level to a more advanced skill enabled the earlier skill to be overlearned, thus preventing some forgetting.

Memory Mechanism 4—Mnemonics: A Picture Retains a Thousand Words

The final tool common to many ultralearners I encountered was mnemonics. There are many mnemonic strategies, and covering them all is outside the scope of this book. What they have in common is that they tend to be hyperspecific—that is, they are designed to remember very specific patterns of information. Second, they usually involve translating abstract or arbitrary information into vivid pictures or spatial maps. When mnemonics work, the results can be almost difficult to believe. Rajveer Meena, the Guinness World Record holder for memorizing digits of the mathematical constant pi, knows the number to 70,000 decimal places.¹⁴ Master mnemonicists, who compete in championships of memory, can memorize the order of a deck of cards in under sixty seconds and can repeat a poem verbatim after only a minute or two of studying. These feats are quite impressive, and even better, they can be learned by anyone patient enough to apply them. How do they work? One common, and useful, mnemonic is known as the keyword method. The method works by first taking a foreign-language word and converting it into something it sounds like in your native language. If I were doing this with French, for example, I might take the word *chavirer* (to capsize) and convert it into “shave an ear,” to which it is close enough in sound for the latter to serve as an effective cue for recalling the original word. Next I create a mental image that combines the sounds-like version of the foreign word and an image of its translation in a fantastical and vivid setting that is bizarre and hard to forget. In this case, I could imagine a giant ear shaving a long beard while sitting in a boat that capsizes. Then, whenever I need to remember what “capsize” is in French, I think of capsizing, recall my elaborate picture, which

links to “shaving an ear” and thus . . . chavirer. This process sounds needlessly complicated and elaborate at first, but it benefits from converting a difficult association (between arbitrary sounds and a new meaning) into a few links that are much easier to associate and remember. With practice, each conversion of this type may take only fifteen to twenty seconds, and it really does help with remembering foreign-language words. This particular kind of mnemonic works for this purpose, but there are others that work for remembering lists, numbers, maps, or sequences of steps in a procedure. For a good introduction to this topic, I highly recommend Joshua Foer’s book *Moonwalking with Einstein: The Art and Science of Remembering Everything*.

Mnemonics work well, and with practice, anyone can do them. Why, then, are they not front and center in this chapter, instead of at the end? I believe that mnemonics, like SRS, are incredibly powerful tools. And as tools, they can open new possibilities for people who are not familiar with them. However, as someone who has spent much time exploring them and applying them to real-world learning, their applications are quite a bit narrower than they first appear, and in many real-world settings they simply aren’t worth the hassle.

I believe there are two disadvantages to mnemonics. The first is that the most impressive mnemonics systems (like the one for memorizing thousands of digits of the mathematical constant pi), also require a considerable up-front investment. After you’re done, you can memorize digits easily, but this isn’t actually a very useful task. Most of our society adapts around the fact that people generally cannot memorize digits, so we have paper and computers do it for us. The second disadvantage is that recalling from mnemonics is often not as automatic as directly remembering something. Knowing a mnemonic for a foreign-language word is better than failing to remember it entirely, but it’s still too slow to allow you to fluently form sentences out of mnemonically remembered words. Thus mnemonics can act as a bridge for difficult-to-remember information, but it’s usually not the final step in creating memories that will endure forever.

Mnemonics, therefore, are an incredibly powerful if somewhat brittle tool. If you are doing a task that requires memorizing highly dense information in a very specific format, especially if the information is going to be used over a few weeks or months, they can enable you to do things with your mind that you might not have thought possible. Alternatively, they can be used as an intermediate strategy to smooth initial information acquisition when the information is quite dense. I’ve found them useful for language learning and terminology, and, paired with SRS, they can form an effective bridge from feeling as though there’s no way you can possibly remember everything to remembering it so deeply that you can’t possibly forget. Indeed, in a world before paper, computers, and other externalized memories, mnemonics were the main game in town. However, in the modern world, which has developed excellent coping mechanisms for the fact that most people cannot remember things as a computer can, I feel that mnemonics tend to serve more as cool tricks than as a foundation you should base your learning efforts on. Still, there is a devoted subset of ultralearners who are fiercely committed to applying these techniques, so my word shouldn’t be the final verdict.

Winning the War Against Forgetting

To retain knowledge is ultimately to combat the inevitable human tendency to forget. This process occurs in all of us, and there’s no way to avoid it

completely. However, certain strategies—spacing, proceduralization, overlearning, and mnemonics—can counteract your short- and long-term rates of forgetting and end up making a huge difference in your memorization.

I opened this chapter by discussing Nigel Richards's mysterious Scrabble mastery. How he is able to recall so many words so quickly and see them in a set of scrambled tiles will likely remain an enigma. What we do know about him fits the picture of other ultralearners who have dominated memory-intensive subjects: active recall, spaced rehearsal, and an obsessive commitment to intense practice. Whether you or I have the will to go as far as Richards does is an open question, but with hard work and a good strategy, it seems likely to me that the battle against forgetting need not be a losing one. Though Richards's Scrabble practice may give him the benefit of memorizing words he doesn't know the meaning of, real life tends to reward a different kind of memory: one that integrates knowledge into a deep understanding of things. In the next principle, we'll look at going from memory to intuition.

Chapter 11: Principle 8: Intuition: Dig Deep Before Building Up

To the world, he was an eccentric professor and Nobel Prize–winning physicist; to his biographer, he was a genius; but to those who knew him, Richard Feynman was a magician. His colleague the mathematician Mark Kac once posited that the world holds two types of geniuses. The first are ordinary geniuses: “Once we understand what they have done we feel certain that we, too, could have done it.” The other type are magicians, whose minds work in such inscrutable ways that “Even after we understand what they have done, the process by which they have done it is completely dark.” Feynman, by his reckoning, was “a magician of the highest caliber.”¹

Feynman could take problems others had worked on for months and immediately see the solution. In high school, he competed in mathematics tournaments, where he would often get the correct answer while the problem was still being stated. While his competitors had just begun to compute, Feynman already had the answer circled on the page. In his college days, he competed in the Putnam Mathematics Competition, with the winner receiving a paid scholarship to Harvard. This competition is notoriously difficult, requiring clever tricks rather than straightforward application of previously learned principles. Time is also a factor, and some examination sessions have a median score of zero, meaning the typical competitor didn’t get even one right. Feynman walked out of the exam early. He scored first place, with his fraternity brothers later being amazed at the drastic gap between Feynman’s score and the next four on the list. During his work on the Manhattan Project, Niels Bohr, then one of the most famous and important living physicists, asked to speak with Feynman directly, to run his ideas by the young grad student before talking with the other physicists. “He’s the only guy who’s not afraid of me” was Bohr’s explanation. “[He] will say when I’ve got a crazy idea.”²

Nor was Feynman’s magic restricted to physics. As a child he went around fixing people’s radios, in part because paying an adult for repairs in the Depression was too costly but also because the radio owners marveled at his process. Once, while he was lost in thought trying to figure out why a radio was producing an awful noise as it started up, the owner of the radio got impatient. “What are you doing? You come to fix the radio, but you’re only walking back and forth!” “I’m thinking!” came the reply, at which the owner, startled at the boldness for which Feynman would later become famous, laughed. “He fixes radios by thinking!”

As a young man during the construction of the atomic bomb in the Manhattan Project, he occupied his free time picking the locks of his supervisors’ desks and cabinets. He once broke into a senior colleague’s filing cabinet, where the secrets for building a nuclear bomb were kept, as a practical joke. Another time, he demonstrated his technique to a military official, who, instead of fixing the security flaw, decided the proper course was to warn everyone to keep Feynman away from their safes! Later, upon meeting a locksmith, he found that his reputation had grown to the point where the professional said, “God! You’re Feynman—the great safecracker!” He also created the impression of being a human calculator. On a trip to Brazil, he went toe to toe against an abacus salesman, computing difficult figures such as the cube root of 1,729.03. Not only did Feynman get the right answer, 12.002, but he got it to more decimal places than the abacus salesman, who was still furiously calculating to get to 12 when Feynman

displayed his five-digit result. This ability impressed even other professional mathematicians, to whom he argued that he could, within one minute, get the answer to any problem that could be stated in ten seconds to within 10 percent of the correct number. The mathematicians threw questions at him such as “e to the power of 3.3” or “e to the power of 1.4,” and Feynman managed to spit back the correct answer almost immediately.

Demystifying Feynman's Magic

Feynman was certainly a genius. Many people, including his biographer James Gleick, are satisfied to leave it at that. A magic trick, after all, is most dazzling when you don't know how it is done. Perhaps this is why many accounts of the man have focused on his magic instead of his method.

Though Feynman was quite smart, his magic had its gaps. He excelled in math and physics but was abysmal in the humanities. His college grades in history were in the bottom fifth of his class, in literature in the bottom sixth, and his fine arts grades were worse than those of 93 percent of his fellow students. At one point, he even resorted to cheating on a test to pass. His intelligence, measured while he was in school, scored 125. The average college graduate has a score of 115, which puts Feynman only modestly higher. Perhaps, as has been argued afterward, Feynman's genius failed to be captured in his IQ score, or it simply was a poorly administered test.

However, for someone so celebrated for a mind beyond comprehension, these facts remind us that Feynman was mortal.

What about Feynman's mental calculus? In this case, we have Feynman's words himself for how he could compute so much faster than the abacus salesman or his mathematician colleagues. The cube root of 1,729.03? Feynman explained, “I happened to know that a cubic foot contains 1728 cubic inches, so the answer is a tiny bit more than 12. The excess, 1.03, is only one part in nearly 2000, and I had learned in calculus that for small fractions, the cube root's excess is one-third of the number's excess. So all I had to do was find the fraction 1/1728, and multiply by 4.” The constant e to the power of 1.4? Feynman revealed, “because of radioactivity (mean-life and half-life), I knew the log of 2 to the base e, which is .69315 (so I also knew that e to the power of .7 is nearly equal to 2).” To go to the power of 1.4, he'd just have to multiply that number against itself. “[S]heer luck,” he explained.³ The secret was his impressive memory for certain arithmetic results and an intuition with numbers that enabled him to interpolate. However, the lucky picks of his examiners allowed him to leave an impression of a magical ability to calculate.

How about the famous lock picking? Once again, it was magic, in the same sense as a magician performing well-practiced tricks. He obsessed over figuring out how combination locks worked. One day he realized that by fiddling with a lock when it was open, he could figure out the last two numbers on the safe. He would write them down on a note after he left the person's office and then could sneak back in, crack the remaining number with some patience, and leave ominous notes behind.

Even his magical intuition for physics had its explanation: “I had a scheme, which I still use today when somebody is explaining something that I'm trying to understand: I keep making up examples.” Instead of trying to follow an equation, he would try to imagine the situation it described. As more information was given, he'd work it through on his example. Then whenever his interlocutor made a mistake, he could see it. “As they're telling me the conditions of the theorem, I construct something which fits all the conditions.

You know, you have a set (one ball)—disjoint (two balls). Then the balls turn colors, grow hairs, or whatever, in my head as they put more conditions on. Finally they state the theorem, which is some dumb thing about the ball which isn't true for my hairy green ball thing, so I say, 'False!'"⁴

Magic, perhaps, Feynman did not possess, but an incredible intuition for numbers and physics he certainly did. This might downplay the idea that his mind worked in a fundamentally different way from yours or mine, but it doesn't negate the impressiveness of his feats. After all, even knowing the logic behind Feynman's sleight of hand, I'm certain I wouldn't have been able to calculate the numbers he did so effortlessly or follow some complex theory in my mind's eye. This explanation doesn't provide the satisfying "Aha!" that it would have had the magician's trick been revealed as something trivial. Therefore, we need to dig deeper to an understanding of how someone such as Feynman could develop this incredible intuition in the first place.

Inside the Mind of the Magician

Psychological researchers have investigated the problem of how intuitive experts, such as Feynman, think differently about problems than novices do. In a famous study, advanced PhDs and undergraduate physics students were given sets of physics problems and asked to sort them into categories.⁵ Immediately, a stark difference became apparent. Whereas beginners tended to look at superficial features of the problem—such as whether the problem was about pulleys or inclined planes—experts focused on the deeper principles at work. "Ah, so it's a conservation of energy problem," you can almost hear them saying as they categorized the problem by what principles of physics they represented. This approach is more successful in solving problems because it gets to the core of how the problems work. The surface features of a problem don't always relate to the correct procedure needed to solve it. The students needed much more trial and error to home in on the correct method, whereas the experts could immediately start with the right approach.

If the principles-first way of thinking of problems is so much more effective, why don't students start there instead of attending to superficial characteristics? The simple answer may be that they can't. Only by developing enough experience with problem solving can you build up a deep mental model of how other problems work. Intuition sounds magical, but the reality may be more banal—the product of a large volume of organized experience dealing with the problem.

Another study, this time comparing chess masters and beginners, offered an explanation of why this might be so.⁶ The memory for chess positions of experts and novices was tested by showing them a particular chess setup and then asking them to re-create it on an empty board. The masters could recall far more than the beginners. The new players needed to put down pieces one by one and were often unable to fully remember all the details of the position. The masters, in contrast, remembered the board in larger "chunks" with several pieces corresponding to a recognizable pattern put down at the same time. Psychologists theorize that the difference between grand masters and novices is not that grand masters can compute many more moves ahead but that they have built up huge libraries of mental representations that come from playing actual games. Researchers have estimated that having around 50,000 of these mental "chunks" stored in long-term memory is necessary to reach expert status.⁷ These representations allow them to take a complex

chess setup and reduce it to a few key patterns that can be worked with intuitively. Beginners, who lack this ability, have to resort to representing each piece as a single unit and are therefore much slower.*

This facility of chess grand masters, however, is limited to the patterns that come from real chess games. Give beginners and experts a randomized chess board (one that doesn't arise from normal play), and the experts no longer display the same marked advantage. Without the library of memorized patterns at their disposal, they have to resort to the beginner's method of remembering the board piece by piece.

This research gives us a glimpse into how the mind of a great intuitionist such as Feynman operated. He, too, focused on principles first, building off examples that cut straight to the heart of what the problem represented rather than focusing on superficial features. His ability to do this was also built off an impressive library of stored physics and math patterns. His mental calculation feats seem impressive to us but were trivial to him, because he happened to know so many mathematical patterns. Like chess grand masters, when given real physics problems he excelled because he had built a huge library of patterns from real experiences with physics. However, his intuition, too, would fail him when the subject of his study wasn't built on those assumptions. Feynman's mathematician friends would test him on counterintuitive theorems from mathematics. His intuition there would fail when properties of the procedure (such as that an object can be cut into infinitely small pieces) defied the normal physical limitations that aided his intuition elsewhere.

Feynman's magic was his incredible intuition, coming from years of playing with the patterns of math and physics. Could emulating his approach to learning enable someone else to capture some of that magic? Let's look at some of Feynman's hallmark approaches to learning and solving problems and try to reveal some of the magician's secrets.

How to Build Your Intuition

Simply spending a lot of time studying something isn't enough to create a deep intuition. Feynman's own experience demonstrates this. On numerous occasions, he would encounter students who memorized solutions to a particular problem but failed to see how they applied outside the textbook domain. In one story, he tricked some of his classmates into believing that a French curve (a device for drawing curved lines) was special because, no matter how you hold it, the bottom is tangent to a horizontal line. This, however, is true of any smooth shape, and it is an elementary fact of calculus that his fellow classmates should have realized. Feynman saw this as an example of a particularly "brittle" way of learning things, since students didn't really think about relating what they had learned to problems outside the textbook.

How, then, can someone avoid a similar fate—spending a lot of time learning something without really developing the flexible intuition for it that made Feynman famous? There's no precise recipe for doing so, and a healthy dose of experience and smarts certainly helps. However, Feynman's own account of his learning process offers some useful guidelines for how he did things differently.

Rule 1: Don't Give Up on Hard Problems Easily

Feynman was obsessed with solving problems. Starting in his childhood days of tinkering with radios, he would work stubbornly on a problem until it yielded. Sometimes, when the owner of the radio would get impatient, he

recalled, “If [he] had said, ‘Never mind, it’s too much work,’ I’d have blown my top, because I want to beat this damn thing, as long as I’ve gone this far.”⁸ This tendency carried over into mathematics and physics. He’d often eschew easier methods, such as the Lagrangian technique, forcing himself to painstakingly calculate all the forces by hand, simply because with the latter method he came to understand it better. Feynman was a master at pushing farther on problems than others expected of him, and this itself might have been the source of many of his unorthodox ideas.

One way you can introduce this into your own efforts is to give yourself a “struggle timer” as you work on problems. When you feel like giving up and that you can’t possibly figure out the solution to a difficult problem, try setting a timer for another ten minutes to push yourself a bit further. The first advantage of this struggle period is that very often you can solve the problem you are faced with if you simply apply enough thinking to it. The second advantage is that even if you fail, you’ll be much more likely to remember the way to arrive at the solution when you encounter it. As mentioned on the chapter on retrieval, difficulty in retrieving the correct information—even when the difficulty is caused by the information not being there—can prime you to remember information better later.

Rule 2: Prove Things to Understand Them

Feynman told a story of his first encounter with the work by the physicists T. D. Lee and C. N. Yang.⁹ “I can’t understand these things that Lee and Yang are saying. It’s all so complicated,” he declared. His sister, lightly teasing him, remarked that the problem wasn’t that he couldn’t understand it but that he hadn’t invented it. Afterward, Feynman decided to read through the papers meticulously, finding that they weren’t actually so difficult but that he had simply been afraid to go through them.

Though this story illustrates one of Feynman’s quirks, it is also revealing because it illustrates a major point in his method. Feynman didn’t master things by following along with other people’s results. Instead, it was by the process of mentally trying to re-create those results that he became so good at physics. This could be a disadvantage at times, since it caused him to repeat work and reinvent processes that already existed in other forms. However, his drive to understand things by virtue of working through the results himself also assisted in building his capacity for deep intuition.

Feynman was not alone in this approach. Albert Einstein, as a child, built his intuitive powers by trying to prove propositions in math and physics. One of Einstein’s earliest mathematical forays was trying to prove the Pythagorean Theorem on the basis of similar triangles.¹⁰ What this approach indicates is that both men had a tendency to dig much deeper before they considered something to be “understood.” Feynman’s scoffing at not understanding Lee and Yang wasn’t because there was no understanding; indeed, he was familiar with much of the background work on the problem. Instead, it was probably because his notion of understanding was much deeper and more based on demonstrating results himself, rather than merely nodding along while reading.

The challenge of thinking you understand something you don’t is unfortunately a common one. Researcher Rebecca Lawson calls this the “illusion of explanatory depth.”¹¹ At issue here is the notion that we judge our own learning competency, not directly but through various signals. Assessing whether or not we know a factual matter, such as what is the capital of France, is quite easy—either the word “Paris” comes up in your mind, or it

doesn't. Asking whether you understand a concept is a lot harder because you may understand it a little, but not enough for the purposes at hand.

Here's a perfect thought experiment to help you understand the problem.

Get out a piece of paper, and try, briefly, to sketch how a bicycle looks. It doesn't need to be a work of art; just try to place the seat, handles, tires, pedals, and bike chain in the right place. Can you do it?

Don't cheat by just trying to visualize the bicycle. Actually see if you can draw it. If you don't have a pencil or paper handy, you can simulate it by saying which things connect to what. Have you tried it?

Interestingly, Rebecca Lawson's study asked participants to do exactly this. As the illustrations clearly show, most participants had no idea how the machines were assembled, even though they used them all the time and believed they understood them quite well. The illusion of understanding is very often the barrier to deeper knowledge, because unless that competency is actually tested, it's easy to mislead yourself into thinking you understand more than you do. Feynman's and Einstein's approach to understanding propositions by demonstrating them prevents this problem in a way that's hard to do otherwise.¹²

Were you one of the lucky ones who managed to put the chains on correctly? Try the exercise again, except this time with a can opener. Can you explain how it works? How many gears are there? How does it cut the lid open? This one is much harder, yet most of us would say we understand can openers!

Rule 3: Always Start with a Concrete Example

Human beings don't learn things very well in the abstract. As the research on transfer demonstrates, most people learn abstract, general rules only after being exposed to many concrete examples. It's not possible to simply present a general principle and expect that you can apply it to concrete situations. As if presaging this observation, Feynman himself would supply concrete examples even when they were not given. Working through an explicit example in his mind's eye, he could follow along and see what the math was trying to demonstrate.

This process of following along with one's own example forces a deeper level of processing the material as it is being presented. A finding from the literature on memory, known as the levels-of-processing effect, suggests that it isn't simply how much time you spend paying attention to information that determines what you retain but, crucially, how you think about that information while you pay attention to it. In one study of this effect, participants were asked to review a list of words; half of them were told it would be for a test (and thus they were motivated to learn it), while the others were simply told to review the list.¹³ Within each group, participants were again split by what orienting technique they used to review the list. Half were asked to notice whether or not the words contained the letter e, a relatively shallow level of processing, while the others were asked if the word was pleasant or not, a deeper processing of the meaning of the word, not merely its spelling. The result was that motivation played no difference; telling students to study for a test didn't impact how much they retained. However, the orienting technique did make a large difference. Those who processed the words deeply remembered almost twice as much as those who simply scanned their spelling.¹⁴

Feynman's habit of developing a concrete instance of a problem can be seen as an example of this deeper form of processing, which not only

enhances later retention but also fosters an intuitive understanding. This technique also enables some feedback, because when it's not possible to imagine an appropriate example, that's evidence that you don't understand something well enough and would benefit from going back a few steps and learning the material better before continuing. Using feedback-rich processes to test whether or not he knew something was a hallmark of Feynman's learning style.

Rule 4: Don't Fool Yourself

"Don't fool yourself" was one of Feynman's most popular aphorisms, to which he added, "and you're the easiest person to fool." He was deeply skeptical of his own understanding. He presaged the current replication crisis in psychology, attacking what he perceived as many social scientists fooling themselves into believing they had discovered something they had not. I suspect that part of this insight arose from the fact that he had cultivated such rigorous standards for what he counted as knowing.

The Dunning-Kruger effect occurs when someone with inadequate understanding of a subject nonetheless believes he or she possesses more knowledge about the subject than the people who actually do.¹⁵ This can occur because when you lack knowledge about a subject, you also tend to lack the ability to assess your own abilities. It is true that the more you learn about a subject, the more questions arise. The reverse also seems to be true, in that the fewer questions you ask, the more likely you are to know less about the subject.

One way to avoid this problem of fooling yourself is simply to ask lots of questions. Feynman took this approach himself: "Some people think in the beginning that I'm kind of slow and I don't understand the problem, because I ask a lot of these 'dumb' questions: 'Is a cathode plus or minus? Is an anion this way, or that way?'"¹⁶ How many of us lack the confidence to ask "dumb" questions? Feynman knew he was smart and had no problem asking them. The irony is that by asking questions with seemingly obvious answers, he also noticed the not-so-obvious implications of the things he studied.

The opposite tendency, to avoid asking questions in the vain attempt to appear knowledgeable, has considerable costs. While lecturing in Brazil, Feynman's students would often complain when he asked simple questions that they knew the answers to already, instead of just lecturing. Why waste valuable classroom time on such exercises? The answer, Feynman eventually realized, was that they didn't know the answers but didn't want to admit it in front of everyone else in the class, wrongly assuming that they were the only ones who didn't know it. Explaining things clearly and asking "dumb" questions can keep you from fooling yourself into thinking you know something you don't.

The Feynman Technique

When I first read about Feynman, I was inspired to try to formulate many of these different observations into a concrete method I could apply to my own studies. What resulted was something I named the Feynman Technique and applied extensively during my MIT Challenge. The purpose of using this technique is to help develop intuition about the ideas you are learning. It can be used when you don't understand an idea at all or simply when you understand something a little but really want to turn it into a deep intuition.

The method is quite simple:

1. Write down the concept or problem you want to understand at the top of a piece of paper.

2. In the space below, explain the idea as if you had to teach it to someone else.

1. If it's a concept, ask yourself how you would convey the idea to someone who has never heard of it before.

2. If it's a problem, explain how to solve it and—crucially—why that solution procedure makes sense to you.

3. When you get stuck, meaning your understanding fails to provide a clear answer, go back to your book, notes, teacher, or reference material to find the answer.

The crux of this method is that it tries to dispel the illusion of explanatory depth. Since many of our understandings are never articulated, it's easy to think you understand something you don't. The Feynman Technique bypasses this problem by forcing you to articulate the idea you want to understand in detail. Just as drawing a bicycle quickly confirms whether you have a basic grasp of how it is put together, using this technique will quickly reveal how much you really understand of your subject. Now any gaps in your understanding will become obvious as you struggle to explain key parts of the idea.

The technique itself has some nuances and can be applied in a few different ways that might be helpful, depending on your specific intuitive deficit.

Application 1: For Things You Don't Understand at All

The first way to use this approach is when you don't understand something at all. In this case, the easiest way is to do it with the book in hand and go back and forth between your explanation and the one in the book. This lacks the benefits of retrieval practice, but it can often be essential when the explanation you've been given baffles you. Feynman himself did something similar when presented with what he saw to be philosophical gobbledygook:

I had this uneasy feeling of "I'm not adequate," until finally I said to myself, "I'm going to stop,

and read one sentence slowly, so I can figure out what the hell it means."

So I stopped—at random—and read the next sentence very carefully. I can't remember it precisely, but it was very close to this: "The individual member of the social community often

receives his information via visual, symbolic channels." I went back and forth over it, and translated. You know what it means? "People read."¹⁷

Although Feynman's method was aimed more at illustrating the deliberately confusing nature of the prose rather than trying to understand a nuanced meaning, the same method can help whenever you're learning anything that goes over your head.

I used this technique when taking a class on machine vision during the MIT Challenge. I didn't understand photogrammetry, a technique of determining the 3D shape of an object based on a series of 2D pictures taken under different lighting conditions. It involved some tricky concepts, so I wasn't quite sure how it worked. With my textbook at my side, I wrote a few pages of notes, trying to sketch out the broad strokes of the idea so I could get the general gist of it.¹⁸

Application 2: For Problems You Can't Seem to Solve

A second way to apply this is for solving a difficult problem or mastering a technique. In this instance, it's very important to go through the problem step by step alongside the explanation you generate, rather than simply summarizing it. Summarizing may end up skipping over the core difficulties

of the problem. Going deeper may take time, but it can help you get a strong grasp over a new method in one go, rather than needing numerous repetitions to memorize the steps.

I applied this to a class in computer graphics for a technique I was struggling with called grid acceleration. This is a method of speeding up the performance of ray-traced rendering systems by avoiding analyzing objects that “obviously” won’t be on the part of the screen you’re drawing. To get a better handle on this, I walked through the problem with the technique, drawing a little snowman that I imagined rendering, with lines shooting out of an eyeball representing the camera.¹⁹

Application 3: For Expanding Your Intuition

A final way to apply this method is to ideas that are so important that it would really help if you had a great intuition about them. In this application of the method, instead of focusing on explaining every detail or going along with the source material, you should try to focus on generating illustrative examples, analogies, or visualizations that would make the idea comprehensible to someone who has learned far less than you have. Imagine that instead of trying to teach the idea, you are being paid to write a magazine article explaining the idea. What visual intuitions would you use to pin down the abstractions? Which examples would flesh out a general principle? How could you make something confusing feel obvious?

I applied this to understanding the concept of voltage in an early class on electromagnetism during the MIT Challenge. Though I was comfortable using the concept in problems, I didn’t feel that I had a good intuition of what it was. It’s obviously not energy, electrons, or flows of things. Still, it was hard to get a mental image of an abstract concept on a wire. Going through this technique and comparing the equations to the ones for gravity, it’s clear that voltage is to the electrical force as height is to the gravitational force. Now I could form a visual image. The wires were like troughs of water at different heights. Batteries were like pumps, moving the water up. Resistors were like hoses dropping down, of various widths to impede the flow of water draining down. Although this picture of troughs and hoses wasn’t necessary for solving the equations, it stuck with me and helped me reason my way out of new situations more easily than if voltage had just been an abstract quantity.

Demystifying Intuition

When many people look at a genius like Richard Feynman, they’re inclined to focus on his seemingly effortless intuitive leaps. In his playful style and rebellious impulses, he may seem to defy the stereotype that learning requires hard work. However, as we go beneath the surface, it becomes clear that he shared much in common with the other ultralearners I’ve studied. He worked hard on understanding things, and he put incredible amounts of his spare time into mastering the methods that made his intuition work. In his early days in college, he and a friend went back and forth over the early books on quantum mechanics, racing ahead of their classmates to understand it. He even made a meticulous timetable to allocate hours to his many intellectual pursuits. Even in his trivial obsessions, he displayed a streak for aggressive methods; while learning lock picking, for example, he trained himself to go through all the possible combinations, practicing them repeatedly: “I got it down to an absolute rhythm so I could try the 400 possible back numbers in less than half an hour. That meant I could open a safe in a maximum of eight hours—with an average time of four hours.”²⁰

When people hear about geniuses, especially the iconoclastic ones such as Feynman, there's a tendency to focus on their gifts and not their efforts. I have no doubt that Feynman possessed gifts. But perhaps his greatest one was his ability to merge tenacious practice and play. He approached picking locks with the same enthusiasm for solving puzzles that he did for unraveling the secrets of quantum electrodynamics. It's this spirit of playful exploration that I want to turn to in the final principle of ultralearning: experimentation.

Chapter 12: Principle 9: Experimentation: Explore Outside Your Comfort Zone

If you were to read his story without seeing his art, Vincent van Gogh would be the last person you would expect to become one of the most famous painters of all time. He started at a late age, twenty-six. Art is a field of precocity, and famous masters typically display their gifts early. Pablo Picasso's cubist style, for example, came out of his already being able to paint realistically as a child, allowing him to boldly declare that it had taken him "four years to paint as Rafael, but a lifetime to paint like a child." Leonardo da Vinci was apprenticed as a painter in his teens. One story has him, as a youth, painting a monster on a peasant's shield only to have it resold to the duke of Milan. Salvador Dalí had his first exhibit before his fourteenth birthday, already showcasing the talent that would make him famous. Van Gogh, in contrast, was delayed and did not possess any obvious signs of ability. It was only after failing as an art dealer and minister that he picked up the brush. An art seller and family friend, H. G. Tersteeg, believed his artistic aspirations were put on to mask his laziness. "You started too late," he declared. "Of one thing I am sure, you are no artist. . . . This painting of yours will be like all the other things you started, it will come to nothing."¹

Worse than the fact that he started late, however, was that van Gogh simply wasn't very good at drawing. His drafting was crude and childlike. When he finally convinced models to sit for portraits—no small task in light of the Dutchman's famously difficult personality—it took him many attempts to get anything resembling a likeness. While in a brief stint at a Parisian atelier, he even studied next to future leaders of the Post-Impressionist movement, such as Henri de Toulouse-Lautrec. However, unlike the effortless quality with which Toulouse-Lautrec captured the likeness of a scene with a few flicks of his wrist, van Gogh struggled. "We considered his work too unskillful," one classmate recalled. "His drawings had nothing remarkable about them."² In the end, his inability to fit in with his classmates, lack of talent, and off-putting manners had him leaving the studio after less than three months.

His late start and lack of obvious talent were compounded by his temperament. Nearly everyone who entered his life would eventually reject him, as his manic enthusiasm and fraternal solidarity would inevitably sour into bitter fights with nearly every person he met. Near the end of his life, he was routinely placed in mental asylums, varying diagnosed with disorders from "acute mania with generalized delirium" to "a kind of epilepsy." His outbursts, or "attacks," as he referred to them, alienated him from people who could potentially serve as his peers, mentors, and teachers. As a result, despite having attempted formal schooling, van Gogh was largely self-taught, capturing only brief moments of more traditional education in the moments during which he could hold on to friendships before pushing people away. It was van Gogh's mysterious and untimely death that cut short the artistic career that was so late to begin. At thirty-seven, he died of a bullet wound to the stomach. Although his death was suspected to be a suicide, his biographers Steven Naifeh and Gregory White Smith consider accident or foul play more likely; he may possibly even have been shot by one of the village youths who played pranks on him and called him the *fou roux*, or

“crazed redhead.”

In spite of all this, van Gogh has become one of the most famous painters of all time. The *Starry Night*, *Irises*, and *Vase with Fifteen Sunflowers* have become icons. On four separate occasions, a van Gogh piece has become the most expensive painting ever sold, including his *Portrait of Dr. Gachet*, which was sold for more than \$82 million.³ Van Gogh’s signature swirls of color, thick impasto application, and strong outlines have made many people consider his paintings some of the greatest of all time.

How can we explain these discrepancies? How does someone who starts late, with no obvious talent and many handicaps, nonetheless become one of the world’s greatest artists, with one of the most recognizable and distinctive styles? To understand van Gogh, I want to turn to the ninth and final principle of ultralearning: experimentation.

How van Gogh Learned to Paint

Put yourself in van Gogh’s shoes for a moment. You’ve failed miserably as an art dealer, despite your family connections. You’ve failed as a preacher. Now you’re embarking on a new profession—painting—even though you have difficulties in drawing things accurately. What would you do? Van Gogh’s response to this challenge was a pattern that would repeat throughout his life. First, he would identify a learning resource, method, or style and pursue it with incredible vigor, creating dozens, if not hundreds, of works in that direction. After this burst of intensity, aware of his still-existing deficiencies, he would apply himself to a new resource, method, or style and start again. Although there’s no evidence van Gogh thought of the connection, I see a parallel between this pattern and the one used by successful scientists: hypothesis, experiment, results, repeat. Perhaps inadvertently, van Gogh’s aggressive, experimental strides into painting allowed him to mature into not merely a proficient painter but an unforgettably unique one.

Van Gogh’s experimentation began when he was first trying to become an artist. The normal route to an artistic career in those days was to attend an art school or apprentice in a studio. Van Gogh, due to the fact that others did not see him as possessing much talent and his odd temperament, did not have much luck with those traditional avenues. Therefore he turned to selfeducation, pursuing home-study courses that promised to teach him the basics of drawing. In particular, he made heavy use of Charles Bargue’s *Exercices au fusain* (Charcoal Exercises) and *Cours de dessin* (Drawing Course), as well as Armand Cassagne’s *Guide de l’alphabet du dessin* (Guide to the ABCs of Drawing). They were thick books with graduated exercises on which aspiring artists could work step by step to improve their drawing skill. According to his biographers, van Gogh “devoured these big books . . . page by page, over and over.” Van Gogh himself reported to his brother, Theo, “I have now finished all sixty sheets,” adding “I worked almost a whole fortnight, from early morning until night.”⁴ Copying was another strategy van Gogh employed early on that he would continue late into his artistic career. Jean-François Millet’s *The Sower* was one of his favorite pictures to copy, which he did again and again. He also applied himself to sketching from life early, in particular models for portraits, which he struggled with due to his difficulties with drafting accurately.

Van Gogh studied from other artists, friends, and mentors. Anthon van Rappard convinced him to try out reed pen and ink and adopt the mature artist’s style of short and fast strokes. Another artist, Anton Mauve,

persuaded him to try a variety of different media: charcoal and chalk, watercolor, and Conté crayon. Often those attempts were not successful. During their stay together at the house where van Gogh would later cut off his ear, Paul Gauguin pushed the Dutchman to paint from memory, mute his colors, and adopt new materials for different effects. Those tactics didn't work for van Gogh, whose weaknesses in drafting were exacerbated by not having the scene directly in front of him, and the different materials went against the style that would later make him famous. Experiments, however, needn't always be successful to have value, and van Gogh had many opportunities for trying new techniques.

Van Gogh experimented not just with materials and methods but also with the philosophies that underpinned his art. Although he is most famous for strong, vibrant colors, that wasn't his initial intention. Originally, he leaned toward the profundity of muted, grayer tones, as witnessed in an early work *The Potato Eaters*. "Scarcely any color is not gray," he argued. "In nature one really sees nothing else but those tones or shades."⁵ He was fully convinced of that and based his work on it accordingly. However, he would later switch to the exact opposite: bright, complementary colors, often imposed on a scene rather than being brought out from nature. His stance on contemporary artistic movements flitted about; at first he preferred traditional painting to the new Impressionist style, and later he shifted to the avantgarde, opting for bold forms rather than verisimilitude.

There are two important things to note about van Gogh's experiments in art. The first is the variety of methods, ideas, and resources he applied. Since he struggled with many aspects of painting, I believe that variation was important to his eventually finding a style that would work for him—one that would take advantage of his strengths and diminish the significance of his weaknesses. Although virtuoso talents might be able to latch on to the first style of instruction they are presented with and follow it to completion, others require a great deal of experimentation before the right method sticks. The second important thing to note is his intensity. Like all the ultralearners I've discussed so far, van Gogh was tenacious in his efforts to become an artist. Despite receiving much negative feedback and discouragement, he pursued his art relentlessly, sometimes producing as much as a new painting every day. These two factors, variation and aggressive exploration, enabled him to push through his early obstacles and produce some of the most iconic and brilliant works ever painted.

Experimentation Is the Key to Mastery

When starting to learn a new skill, often it's sufficient simply to follow the example of someone who is further along than you. In discussing the principles of ultralearning, metalearning comes first. Understanding how a subject breaks down into different elements and seeing how others have learned it previously, thus providing an advantageous starting point.

However, as your skill develops, it's often no longer enough to simply follow the examples of others; you need to experiment and find your own path.

Part of the reason for this is that the early part of learning a skill tends to be the best trodden and supported, as everyone begins at the same place. As your skills develop, however, not only are there fewer people who can teach you and fewer students you could have as peers (thus lowering the total market for books, classes, and instructors), but you also start to diverge from those you're learning from. Whereas two complete novices have quite similar knowledge and skills, two experts might have quite different sets of skills that

they've already acquired, thus making improving those skills an increasingly personalized and idiosyncratic adventure.

A second reason for the value of experimentation as you approach mastery is that abilities are more likely to stagnate after you've mastered the basics. Learning in the early phases of a skill is an act of accumulation. You acquire new facts, knowledge, and skills to handle problems you didn't know how to solve before. Getting better, however, increasingly becomes an act of unlearning; not only must you learn to solve problems you couldn't before, you must unlearn stale and ineffective approaches for solving those problems. The difference between a novice programmer and a master isn't usually that the novice cannot solve certain problems. Rather, it's that the master knows the best way to solve a problem, which will be the most efficient and clean and cause the fewest headaches later on. As mastery becomes a process of unlearning over accumulation, experimentation becomes synonymous with learning as you force yourself to go outside your comfort zone and try new things.

A final reason for the increasing importance of experimentation as you approach mastery is that many skills reward not only proficiency but originality. A great mathematician is one who can solve problems others cannot, not merely a person who can solve previously solved problems easily. Successful business leaders are those who can spot opportunities others cannot, not merely those who can copy the style and strategy of those before them. In art, it was not only van Gogh's skill but his originality that made him one of the most celebrated painters to have ever lived. As creativity becomes valuable, experimentation becomes essential.

Three Types of Experimentation

In experimentation you can see different levels play out, both in van Gogh's path as an artist and as a model for your own explorations:

1. Experimenting with Learning Resources

The first place to experiment is with the methods, materials, and resources you use to learn. Van Gogh did this extensively at the beginning of his artistic career, trying out different artistic media, materials, and learning techniques: following home-study courses, watching fellow artists, sketching from life and in the studio, and more. This kind of experimentation is useful in helping you discover the guides and resources that work best for you. It's important, however, that your impulse to experiment be matched with a drive to do the necessary work. Although van Gogh tried many different approaches when he first started teaching himself to draw and paint, he also produced an enormous quantity of work based on each of those methods.

A good strategy to take is to pick a resource (maybe a book, class, or method of learning) and apply it rigorously for a predetermined period of time. Once you apply yourself aggressively to that new method, you can step back and evaluate how well it is working and whether you feel it makes sense to continue with that approach or try another.

2. Experimenting with Technique

In the beginning, experimentation tends to focus on materials. However, in most domains of learning, the options for what to learn next expand faster and faster, so the question becomes not "How can I learn this?" but "What should I learn next?" Languages are a prime example. The same basic set of vocabulary and phrases dominates most beginner resources. As you improve, however, the amount of things you could possibly learn next becomes larger and larger. Should you learn to read literature? Converse fluently on a

professional topic? Read comic books? Have business discussions? The specialized vocabulary, phrases, and cultural knowledge in each field multiply, so it becomes necessary to choose what to master.

Once again, experimentation plays a pivotal role. Pick some subtopic within the skill you're trying to cultivate, spend some time learning it aggressively, and then evaluate your progress. Should you continue in that direction or pick another? There's no "right" answer here, but there are answers that will be more useful to the specific skill you're trying to master.

3. Experimenting with Style

After you've matured in your learning a bit, the difficulty often switches from which resources to learn from or which techniques you'd like to master to the style you'd like to cultivate. Although there are some skills that have one and only one "correct" way of doing things, this is not true of most. Writing, design, leadership, music, art, and research all involve developing certain styles, which have different trade-offs. Once you master the basics, there is no longer one "right" way to do everything but many different possibilities, all of which have different strengths and weaknesses. This affords another opportunity for experimentation. Van Gogh tried out many different styles for producing art, varying from those of traditional painters such as Millet, to Japanese woodblock prints, and studied the techniques used by his artist friends such as Gauguin and Rappard. There is no one correct answer, although, like van Gogh, you may find that certain styles work better than others with your unique combination of strengths and weaknesses.

The key to experimenting with different styles is to be aware of all the different styles that exist. Once again van Gogh provides a good model, as he spent an enormous amount of time studying and discussing the works of other artists. That gave him a large library of possible styles and ideas he could adapt to his own work. Similarly, you might want to identify masters in your own line of study and dissect what makes their styles successful to see what you can emulate or integrate into your own approach.

In each level of experimentation, the choices broaden and the possible options to explore go up exponentially. There's a tension, therefore, between spending time trying out different resources, techniques, and styles, and concentrating your efforts on a single approach long enough to become proficient at it. This tension often resolves itself as you cycle through exploring a new avenue in learning and then buckling down to learn it deeply before moving on to something else. Whatever else his failings, it was this pattern of trying out an idea and working on it aggressively that van Gogh applied brilliantly.

The Mindset of Experimentation

There are parallels between the mindset required to experiment and what the Stanford psychologist Carol Dweck refers to as growth mindset.⁶ In her research, she distinguishes between two different ways of looking at one's own learning and potential. In a fixed mindset, learners believe that their traits are fixed or innate and thus there's no point in trying to improve them. In a growth mindset, in contrast, learners see their own capacity for learning as something that can be actively improved. In some ways, these two types of mindsets become self-fulfilling prophecies. Those who think they can improve and grow, do; those who think they are fixed and immutable remain stuck.

The parallel with the mindset required for experimentation is clear.

Experimenting is based on the belief that improvements are possible in how

you approach your work. If you think your learning styles are fixed or that you have certain immutable strengths and weaknesses that will keep you from trying out different ways to approach your skills, you won't be able to experiment at all.

I see the experimental mindset as an extension of the growth mindset: whereas the growth mindset encourages you to see opportunities and potential for improvement, experimentation enacts a plan to reach those improvements. The experimental mindset doesn't just assume that growth is possible but creates an active strategy for exploring all the possible ways to reach it. To get into the right mental space for experimenting, you need not only to see your abilities as something you can improve but understand that there is a huge number of potential avenues to do this. Exploration, not dogmatism, is the key to realizing that potential.

How to Experiment

Experimenting sounds simple but can be quite tricky to implement in practice. The reason is that a flurry of random activity doesn't usually translate into mastery. In order to work, experimenting requires understanding what learning problems you're facing and coming up with possible ways to resolve them. Here are a few tactics that can help you integrate experimentation into your ultralearning projects.

Tactic 1: Copy, Then Create

This is the first strategy for experimenting, which we can see in van Gogh's work. Though van Gogh is best known for his original pieces, he also spent a lot of time copying drawings and paintings he liked by other artists. Copying simplifies the problem of experimentation somewhat because it gives you a starting point for making decisions. If you're learning to paint, as van Gogh did, the possibilities of what kinds of art you can create and techniques you can apply are so vast that it can be difficult or impossible to decide among them. However, if you start by emulating another artist, you can use that foothold to venture further in your own creative directions.

This strategy has another advantage beyond simplifying the choices available to you. In attempting to emulate or copy an example you appreciate, you must deconstruct it to understand why it works. This can often highlight things that the other person does exceptionally well that weren't obvious from the beginning. It may also dispel illusions you may have had about an aspect of the work you thought was important but upon emulating the other person's work you realize was not.⁷

Tactic 2: Compare Methods Side-by-Side

The scientific method works by carefully controlling conditions so that the difference between two situations is limited to the variable being studied. You can apply this same process to your experiments in learning by trying two different approaches and varying only a single condition to see what the impact is. By applying two different approaches side by side, you can often quickly get information not only about what works best but about which methods are better suited to your personal style.

I applied this to learning French vocabulary. I wasn't sure how effective mnemonics would be so, for a month, I would find a list of fifty new words every day, put together from my regular reading or random encounters with the language, and for half I would simply look them over with their translations I got from the dictionary. With the other half, I made an effort to use a visual mnemonic to link the two meanings. Then I compared how many of the words I remembered from each list on a later test, with words picked

randomly from each side. The result is something you would probably expect after reading the chapters on retrieval and retention: I remembered the words I used mnemonics for at almost twice the rate of those I didn't. That showed that even if creating the mnemonics took a bit more time, they were worth it. There are two advantages to doing split tests. The first is that as in scientific experiments, you will get much better information about which method works best if you limit the variation to only the factor you want to test. The second is that by solving a problem multiple ways or applying multiple solution styles to it, you will increase your breadth of expertise. Forcing yourself to try different approaches encourages experimentation outside your comfort zone.

Tactic 3: Introduce New Constraints

The challenge of learning in the beginning is that you don't know what to do. The challenge of learning in the end is that you think you already know what to do. It's this latter difficulty that causes us to rerun old routines and old ways of solving problems that are encouraged through habit, not always because the old way is actually best. A powerful technique for pushing out of those grooves of routine is by introducing new constraints that make the old methods impossible to use.

It's practically an axiom of design that the best innovations come from working within constraints. Give a designer unlimited freedom, and the solution is usually a mess. On the other hand, creating specific constraints in how you can proceed encourages you to explore options that are less familiar to you and sharpens your underlying skills. How can you add limitations to force yourself to develop new capacities?

Tactic 4: Find Your Superpower in the Hybrid of Unrelated Skills

The traditional path to mastery is to take a well-defined skill and practice it relentlessly until you have become insanely good at it. This is the path taken by many athletes, who train for decades to perfect their shot, jump, kick, or throw. However, for many areas of creative or professional skills, another, more accessible, path is to combine two skills that don't necessarily overlap to bring about a distinct advantage that those who specialize in only one of those skills do not have. For instance, you might be an engineer who becomes really good at public speaking. You may not be the best possible engineer or the best possible presenter, but combining those two skills could make you the best person to present on engineering topics for your company at conferences, thus giving you access to new professional opportunities. Scott Adams, the creator of Dilbert, likened his own success to following this strategy by combining his background as an engineer with an MBA and a cartoonist.⁸

This level of experimentation often plays out over multiple ultralearning projects. After I completed my MIT Challenge, I could apply the programming knowledge I had obtained to write scripts to automatically generate flash cards for learning Chinese. Such synergies become possible once you start exploring how one skill you've already acquired can impact another.

Tactic 5: Explore the Extremes

Van Gogh's art pushed well outside normal conventions along many dimensions. His thick application of paint was far away from the thin layers of glazes used by Renaissance masters. His quick application was far more rapid than the careful brushstrokes of other painters. His colors were bold,

often garish, instead of subtle. If you were to draw a chart that mapped out van Gogh's style compared with those of other painters, you would probably see that he lay along the extreme in many dimensions.

An interesting result from mathematics is that as you get to higher and higher dimensions, most of the volume of a higher-dimensional sphere lies near its surface. For instance, in two dimensions (a circle), just under 20 percent of its mass lies in the outer shell described by a tenth of the radius. In three dimensions (a sphere), that number rises to almost 30 percent. In ten dimensions, almost three-quarters of the mass is in that outermost layer. You can imagine learning a complex subject as akin to trying to find an optimal point in a region of higher-dimensional space—except that instead of length, width, and height, those dimensions might be the qualitative dimensions of work, such as van Gogh's complementarity of colors, application of paint, or some other aspect of skill that can be applied in some varying degree of intensity. What this means is that the more complicated a domain of skill is (i.e., the more dimensions it contains), the more space will be taken up by applications of that skill that are extreme across at least one of those dimensions. This suggests that for many skills, the best option is going to be extreme in some way, since so many more of the possibilities are themselves extreme. Sticking to the middle and playing it safe isn't the correct approach because that allows you to explore only a small subset of the total possibilities for your work.

Pushing out to an extreme in some aspect of the skill you're cultivating, even if you eventually decide to pull it back to something more moderate, is often a good exploration strategy. This allows you to search the space of possibilities more effectively, while also giving you a broader range of experience.

Experimentation and Uncertainty

Learning is a process of experimenting in two ways. First, the act of learning itself is a kind of trial and error. Practicing directly, getting feedback, and trying to summon up the right answers to problems are all ways of adjusting the knowledge and skills you have in your head to the real world. Second, the act of experimenting also lies in the process of trying out your learning methods. Try out different approaches, and use the ones that work best for you. The principles I've tried to articulate in this book should provide good starting points. But they are guidelines, not iron rules; starting points, not destinations. Only by experimenting will you be able to find the right tradeoffs between different principles—for instance, when directness is more important and when you should focus on drills or whether retention or intuition is the main obstacle to learning. Experimenting will also help you decide among small differences in approach that no list of principles could possibly cover exhaustively.

Having a mindset of experimentation will also encourage you to explore beyond what you feel most comfortable doing. Many people stick to the same routines, the same narrow set of methods, they apply to learning everything. As a result, there are a lot of things they struggle to learn because they don't know the best way to do so. Copying exemplars, running tests, and pushing to extremes are all ways to push outside your ingrained habits and try out something different. That process will teach you not just abstract learning principles but concrete tactics that will accommodate your personality, interests, strengths, and weaknesses. Are you better off learning a language through practicing speaking or engaging in lots of input through movies and

books? Are you better off learning programming by building your own game or working on open-source projects? These questions don't have a single correct answer, and people have achieved success using a wide variety of different methods.

My own experience with learning has been one of constant experimentation. In university, I focused a lot on making associations and connections. During the MIT Challenge, I switched to making practice the foundation. In my first experience learning a language, I was sloppy, speaking English most of the time. In the second round, I experimented with going to another extreme, to see if I could avoid that sticking point. While doing projects, I've had to adjust my methods frequently. Even though it was only thirty days long, my portrait-drawing challenge involved a lot of trial and error from starting by doing sketches and, when my progress using that approach slowed, trying to do sketches even faster to get more feedback. When that, too, had reached its limits, I spent some time learning a different technique altogether to achieve greater accuracy.

Embedded in my successes are many failures—times where I thought I could get something to work and it ended up failing miserably. Early on in learning Chinese, I thought I could use some kind of mnemonic system to remember the words, with colors for tones and memorized symbols for the syllables. That was because my normal sounds-like method for visual mnemonics wasn't working with the words, which all sounded so different from English. The result was a total failure, and it didn't work at all! Other times, my experiments with new methods worked out great. Most of the techniques I've shared in this book thus far started as ideas I wasn't sure would pan out.

Experimentation is the principle that ties all the others together. Not only does it make you try new things and think hard about how to solve specific learning challenges, it also encourages you to be ruthless in discarding methods that don't work. Careful experimentation not only brings out your best potential, it also eliminates bad habits and superstitions by putting them to the test of real-world results.

Chapter 13: Your first Ultra-learning Project

Step 1: Do Your Research

The first step in any project is to do the metalearning research required to give you a good starting point. Planning ahead will avoid a lot of problems and prevent you from having to make drastic changes to your learning plan before you've even started making progress. Research is a bit like packing a suitcase for a long voyage. You may not bring the right items, or you may forget something and need to buy it on the road. However, thinking ahead and packing your bags correctly will prevent a lot of fumbling later. Your ultralearning "packing" checklist should include, at a minimum:

1. WHAT TOPIC YOU'RE GOING TO LEARN AND ITS APPROXIMATE SCOPE.

Obviously, no learning project can begin unless you figure out what you want to learn. In some cases, this is obvious. In others, you may need to do further research to identify which skill or knowledge would be most valuable. If your goal is to learn something instrumentally (to start a business, get a promotion, do research for an article), learning what you need to learn is important and will suggest how wide and deep you need to go. I suggest starting with rather a narrow scope, which can expand as you proceed. "Learning enough Mandarin Chinese to hold a fifteenminute conversation on simple topics" is a lot more constrained than "Learn Chinese," which may include reading, writing, studying history, and more.

2. THE PRIMARY RESOURCES YOU'RE GOING TO USE. This includes books, videos, classes, tutorials, guides, and even people who will serve as mentors, coaches, and peers. This is where you decide what your starting point will be. Examples: "I'm going to read and complete the exercises in a book on Python programming for beginners" or "I'm going to learn Spanish through online tutoring via italki.com" or "I'm going to practice drawing by making sketches." In some subjects, static materials will determine how you proceed. In others, they will be supports to back up your practice. In any case, they should be identified, purchased, borrowed, or enrolled in before you begin.

3. A BENCHMARK FOR HOW OTHERS HAVE SUCCESSFULLY LEARNED THIS SKILL OR SUBJECT. Almost any popular skill has online forums where those who have learned the skill previously can share their approaches. You should identify the things other people who have learned the skill have done to learn it. This doesn't mean you need to follow exactly in their footsteps, but it will prevent you from completely missing something important. The Expert Interview Method in [chapter 4](#) provides a good method for following up on this.

4. DIRECT PRACTICE ACTIVITIES. Every skill and subject you're learning will be used somewhere eventually, even if it's as simple as using it to learn something else. Thinking about how you might use the skill can enable you to start finding opportunities to practice it as early as possible. If direct practice is impossible, you should nonetheless identify opportunities for practice that mimic the mental requirements of using the skill.

5. BACKUP MATERIALS AND DRILLS. In addition to the principal materials and methods you'll be using, it's a good idea to look at possible drills and backup materials you may want to use. Backup materials are often

good if you recognize that a certain tool or set of materials might be useful but you don't want to be overwhelmed in the beginning.

Step 2: Schedule Your Time

Your ultralearning project doesn't need to be an intensive, full-time endeavor to succeed. However, it will require some time investment, and it's better to decide on how much time you are willing to devote to learning in advance than simply hope that you'll find the time later. There are two good reasons for planning your schedule ahead of time. The first is that this way you subconsciously prioritize your project by setting it down on your calendar ahead of other things. The second is that learning is often frustrating and it is almost always easier to click over to Facebook, Twitter, or Netflix. If you don't set aside time to learn, it will be a lot harder to summon up the motivation to do so.

The first decision you should make is how much time you're going to commit. This is often dictated by your schedule. You may have a gap in employment that allows intensive learning, but only for a month.

Alternatively, you may have a full schedule that permits you to devote only a few hours per week to learning something new. Whatever time you can commit, decide on it in advance.

The second decision you need to make is when you are going to learn.

During a few hours on Sunday? By waking up an hour earlier and putting in the time before work? In the evening? During lunch breaks? Once again, the best thing is to do whatever makes it easiest based on your schedule. I recommend setting a consistent schedule that is the same every week, rather than trying to fit in learning when you can. Consistency breeds good habits, reducing the effort required to study. If you have absolutely no choice, an ad hoc schedule is better than none, but it will require more discipline to sustain. If you do have some flexibility in your schedule, you may want to optimize it. Shorter, spaced time chunks are better for memory than crammed chunks are. However, some types of tasks, such as writing and programming, have a long warm-up time that may benefit from longer uninterrupted time chunks. The best way to find out what is best for you is to practice; if you find it takes a long time to warm up, opt for longer spaces in your schedule. If you find you can get to work within a few minutes of starting, shorter chunks of time spread out will be helpful for long-term retention.

The third decision you need to make is the length of time for your project.

I generally prefer shorter commitments to longer ones because they are easier to stick with. An intensive project that lasts a month has fewer potential interruptions from life or from your motivation changing and waning. If you have a big goal you want to accomplish that can't be done in a short time frame, I suggest breaking it up into multiple smaller ones of a few months each.

Finally, take all this information and put it into your calendar. Scheduling all the hours of work on the project in advance has important logistical and psychological benefits. Logistically, this will help you spot potential conflicts in your schedule due to vacations, work, or family events. Psychologically, it will help you remember and act on your initial plan better than if it were written on a piece of paper tucked into a desk drawer. What's more, the act of scheduling demonstrates your seriousness about doing the project.

I can clearly remember writing down my hypothetical studying schedule before starting the MIT Challenge. It had me up and studying by 7 a.m. and working until 6 p.m., with only a short break for lunch. Although my actual

schedule, in practice, rarely reached that ideal (even in my most intensive early days, I almost never got in eleven hours straight), the mere act of writing down the schedule helped prepare me psychologically for the project ahead. If you're unwilling to put time into your calendar, you're almost certainly unwilling to put in time to study. If you're waffling at this stage, that's a good sign your heart isn't really in the right place to get started. As a bonus step, for those who are embarking on longer projects of six months or more, I strongly recommend doing a pilot week of your schedule. This is simple: test your schedule for one week before you commit to it. This will give you firsthand knowledge of how difficult it will be and prevents overconfidence. If you already feel burned out after the first week, you may need to make adjustments. There's no shame in going back and retooling your plan to make it fit your life better. Making this kind of adjustment is a lot better than giving up midway because your plan was doomed from the start.

Step 3: Execute Your Plan

Whatever plan you started with, now is the time to do it. No plan is perfect, and you may realize that what you're doing for learning departs from the ideal, as established by the ultralearning principles. You may notice that your plan relies too much on passive reading rather than retrieval practice. You may see that the way you're practicing is a winding detour away from where you will actually want to use it. You may feel as though you're forgetting things or memorizing them without really understanding them. That's okay. In some cases, you won't be able to have the perfect learning approach because the resources to do so don't exist. However, becoming sensitive to how the way you're learning isn't aligned with the principles is a good way to feel out changes you can make to improve it.

Here are some questions to ask yourself to determine whether you're slipping from the ideal:

1. **METALEARNING.** Have I done research into what are the typical ways of learning this subject or skill? Have I interviewed successful learners to see what resources and advice they can recommend? Have I spent about 10 percent of the total time on preparing my project?
2. **FOCUS.** Am I focused when I spend time learning, or am I multitasking and distracted? Am I skipping learning sessions or procrastinating? When I start a session, how long does it take before I'm in a good flow? How long can I sustain that focus before my mind starts to wander? How sharp is my attention? Should it be more concentrated for intensity or more diffuse for creativity?
3. **DIRECTNESS.** Am I learning the skill in the way I'll eventually be using it? If not, what mental processes are missing from my practice that exist in the real environment? How can I practice transferring the knowledge I learn from my book/class/video to real life?
4. **DRILL.** Am I spending time focusing on the weakest points of my performance? What is the rate-limiting step that is holding me back? Does it feel as though my learning is slowing down and that there's too many components of the skill to master? If so, how can I split apart a complex skill to work on smaller, more manageable components of it?
5. **RETRIEVAL.** Am I spending most of my time reading and reviewing, or am I solving problems and recalling things from memory without looking at my notes? Do I have some way of testing myself, or do I just assume I'll remember? Can I successfully explain what I learned

yesterday, last week, a year ago? How do I know if I can?

6. FEEDBACK. Am I getting honest feedback about my performance early on, or am I trying to dodge the punches and avoid criticism? Do I know what I'm learning well and what I'm not? Am I using feedback correctly, or am I overreacting to noisy data?

7. RETENTION. Do I have a plan in place to remember what I'm learning long term? Am I spacing my exposure to information so it will stick longer? Am I turning factual knowledge into procedures that I'll retain? Am I overlearning the most critical aspects of the skill?

8. INTUITION. Do I deeply understand the things I'm learning, or am I just memorizing? Could I teach the ideas and procedures I'm studying to someone else? Is it clear to me why what I'm learning is true, or does it all seem arbitrary and unrelated?

9. EXPERIMENTATION. Am I getting stuck with my current resources and techniques? Do I need to branch out and try new approaches to reach my goal? How can I go beyond mastering the basics and create a unique style to solve problems creatively and do things others haven't explored before?

Together these principles serve as directions, not destinations. In each case, look at how you're currently progressing through your materials, and see what you could do differently. Do you need to switch resources? Do you need to stick to the same resources but spend more time on a different kind of practice? Should you seek out new environments for feedback, directness, or immersion? These are all subtle adjustments you can make along the way.

Step 4: Review Your Results

After your project is finished (or if you end up putting it on pause for some reason), you should spend a little time analyzing it. What went right? What went wrong? What should you do next time to avoid making those same mistakes?

Not all of your projects will be successful. I've had ultralearning projects that I felt good about. I've had others that didn't work out as well as I had hoped. Although the tendency is to blame willpower and motivation, very often the problems with projects can be traced back to their conception. I worked on one project devoted to improving my Korean, after my trip, by investing five hours per week. It wasn't as successful as I had hoped because I didn't invest enough time in focusing on immersive, direct practice from the get-go. Instead, my study method depended a lot on textbook exercises, which were boring and didn't transfer too well to the real world. If I had thought a little more about it, I would have spent a week or two ahead of time trying to find places to practice, instead of trying to pivot midway, when I was already losing some motivation. This struggle illustrates that mastering the principles is a lifelong process. Even after many experiences learning languages, and knowing what works well, I slipped into a less effective approach because I didn't plan my project adequately. In other cases a project might not work out as you had hoped, but that lesson will still be valuable. I started with a project to learn cognitive science more deeply, going from a book list. Eventually, however, a lot of that project morphed into a desire to do research for this book, which put me into contact with a lot of science, now combined with an outlet for a more direct way to apply it.

Even your successful projects are worth analyzing. They can often tell you more than your failures because the reasons a successful project succeeded are the very elements you want to retain and replicate for the future. With

ultralearning, as with all self-education, the goal isn't merely to learn one skill or subject but to hone and enhance your overall learning process. Each successful project can be refined and improved for the next one.

Step 5: Choose to Maintain or Master What You've Learned

After you've learned your skill and analyzed your efforts, you have a choice to make. What do you want to do with the skill? With no plan in place, most knowledge eventually decays. This can be alleviated somewhat by following the principles of ultralearning. However, all knowledge decays without any form of intervention, so the best time to make a choice about how you're going to handle that is right after you learn something.

Option 1: Maintenance

The first option is to invest enough practice to sustain the skill but without any concrete goal of getting it to a new level. This can often be accomplished by setting up a habit of regular practice, even if it is a minimal one. As mentioned in the chapter on retention, one of the worries I had after the year without English project was that learning languages so intensively over a short period of time might lead not just to rapid learning but to rapid forgetting. As a result, I made an effort to continue practice after the trip finished, spending thirty minutes a week on each language in the first year and thirty minutes a month on each language in the year after that.

Another option is to try to integrate the skill into your life. This is how I maintain my programming skills, where I write Python scripts to handle work tasks that would otherwise be cumbersome or annoying. This kind of practice is more sporadic, but it ensures that I will keep it up enough to make it usable. This kind of lightweight usage is far from the deep math and algorithms I learned from my MIT coursework, but it is enough to keep a foot in the door if I want to embark on a bigger project at a later time.

Forgetting, as was discovered by Hermann Ebbinghaus more than a hundred years ago, falls off with an exponentially decaying curve. That means that memories that are retained for longer are less and less likely to be forgotten when you follow up at a later date. This pattern suggests that maintenance practice, too, can fall off on a decaying rate, so that the bulk of the knowledge you've acquired will be preserved. This means you might want to start with a habit of more serious practice but reduce the time spent on it a year or two after your project is finished to still get most of the benefit, as I did with the languages I studied.

Option 2: Relearning

Forgetting isn't ideal, but for many skills the costs of relearning the skill later are smaller than the costs of keeping it continuously sharp. There are a couple reasons for this. First, you may have learned more than you actually need, so if some of that knowledge selectively decays due to disuse, it is automatically going to be the less important knowledge that you acquired. I studied a lot of MIT subjects that I don't think I'll ever use again, although understanding the gist of them might come in handy later. Therefore, keeping my ability to prove theorems of modal logic, for example, up to date has only marginal value. Knowing what modal logic is and where I might apply it in case I want to learn something that requires it is probably enough.

Relearning is generally easier than first-time learning. Although performance on tests drops off dramatically, the knowledge is likely inaccessible rather than completely forgotten. This means that doing a refresher course or practice series can be enough to reactivate most of it in a

fraction of the time it took to learn it initially. This may be the optimal strategy for subjects that you need to use infrequently and for which situations for using them won't pop up without warning. Often, recognizing that a certain domain of knowledge is helpful for a particular problem type is more important than the details of solving the problem, since the latter can be relearned but forgetting the former will cut you off from solving those problems.

Option 3: Mastery

The third option, of course, is to dive deeper into the skill you have learned. This can be done through continued practice at a lighter pace or by following up with another ultralearning project. A common pattern I've noticed in my own learning is that an initial project covers a wider territory and some basics and exposes new avenues for learning that were previously obscured. You might identify a subtopic or branch of skill within the domain you were learning before that you want to follow up. Otherwise, you may decide to transfer a skill learned in one place to a new domain. One of my goals after returning from my trip to China was to learn to read Chinese better, which had been only an incidental goal while I was traveling there.

Mastery is a long road that extends far beyond a single project. Sometimes the barriers you overcome in your initial effort are enough to clear the way for a slow process of accumulation to reach eventual mastery. In many domains, getting started is quite frustrating, so it's difficult to practice without a certain amount of effort. After that threshold is reached, however, the process switches to being one of accumulating huge swaths of knowledge and therefore can proceed at a more patient pace. On the other hand, some projects will get stuck, and you will need to spend time unlearning and push through your frustrations again to get ahead. Those kinds of projects benefit more from the precise and aggressive methods of ultralearning to reach eventual mastery.

Alternatives to Ultralearning: Low-Intensity Habits and Formal Instruction

At the start of this book, I pointed out that ultralearning is a strategy. Being a strategy implies that it is good for solving certain problems. Given that the practice is somewhat uncommon, I wanted to spend the book focused on this strategy, rather than try to give a diffuse description of all possible ways you can learn effectively. However, now that I've done that, I think it's worthwhile to touch on two other strategies that can work with ultralearning, in different contexts.

None of the ultralearners I encountered approaches learning the same way for every kind of learning they do. Benny Lewis, for example, does do intensive learning projects for languages, but he has learned most of his languages over repeat visits to the countries they are spoken in, digging deeper into languages he previously established in intense bursts. Roger Craig did learn aggressively to win at Jeopardy!, but he also engaged in more leisurely acquisition of trivia when his appearance on the game show wasn't imminent. Being an ultralearner doesn't imply that everything one learns has to be done in the most aggressive and dramatic fashion possible. I want to briefly consider the two main alternative strategies to ultralearning to see how they fit into a bigger picture of lifelong learning.

Alternative Strategy 1: Low-Intensity Habits

Low-intensity habits work well when engaging in learning is spontaneous, your frustration level is low, and learning is automatically rewarding. In these

cases, when the barriers to learning are fairly low, all you need to do is show up. No fancy project, principles, or effort is required. Once you reach a conversational level in a language, for instance, it's often fairly easy to travel and live in a country where it is spoken, accumulating more and more vocabulary and knowledge over a longer period of time. Similarly, once you become good enough at programming to use it for your job, the job itself will push you to learn new things at a regular pace. If you've mastered the basics of a subject so that you can read denser books about it, reading books on the topic is mostly a matter of putting in time, not developing ingenious learning strategies.

Of course, there's a spectrum of habits, from zero-effort, spontaneous engagement to the high-effort, rapid skill acquisition of ultralearning. Most habits are somewhere in between, necessitating a bit of effort but perhaps not the full-scale intensity of an ultralearning project. You may have learned enough Excel to create your own spreadsheet macros, but you don't always find opportunities or time to use it, so you need to push yourself a little to practice. You may have learned public speaking well, but it still takes some guts to go onstage. The decision of whether the right step forward is to set up long-term habits or to create a concentrated ultralearning project is often not crystal clear and may depend more on your personality and life constraints than a hard-and-fast rule.

Habits tend to work best when the act of learning is mostly a process of accumulation, adding new skills and knowledge. Ultralearning and more deliberate efforts are better suited to when improvement in a field requires unlearning ineffective behaviors or skills. Increasing your vocabulary in a foreign language is often a slow process of accumulation; you are learning words you didn't know before. Improving your pronunciation, on the other hand, is an act of unlearning. You're training yourself to use different muscular movements that aren't natural to you. Ultralearning also tends to be better for areas in which learning has greater frustration barriers and psychological obstacles that make any form of practice too great an effort to be an easily established habit.

Throughout this book, we've explored the trade-off that occurs between doing what's effective for learning and what's easy and enjoyable.

Sometimes what's the most fun isn't very effective, and what's effective isn't easy. This trade-off may push you to opt for easier, more enjoyable forms of learning that sacrifice some effectiveness. However, in my own experience, I've noticed that enjoyment tends to come from being good at things. Once you feel competent in a skill, it starts to get a lot more fun. Therefore, although a tension between the two can exist in the short term, I think pursuing aggressive ultralearning projects is often the surer way to enjoy learning more, as you're more likely to reach a level where learning automatically becomes fun.

Alternative Strategy 2: Formal, Structured Education

In the beginning of this book, I explained that ultralearning is self-directed, although not necessarily solitary. Being self-directed is about who is making decisions, not about whether other people are involved. Therefore, there is no contradiction in pursuing ultralearning within a school or university. That might be the best way to learn the skills you want to acquire. Just treat it like any other resource.

That distinction notwithstanding, I think it's worth talking about other reasons you might want to pursue formal education rather than ultralearning.

The most obvious is to acquire credentials. If those are necessary or recommended for your chosen line of work, you might need to be satisfied with making sacrifices for your learning in order to acquire them. The message of this book isn't that you should drop out of school to learn on your own but that you should take control over your own learning, wherever that may be. Another reason to pursue formal education is that it creates a learning environment that may be beneficial. Although many aspects of school are woefully indirect and ineffective, others fare much better. Design and art schools often function like apprenticeships. Some programs allow for team projects that are difficult to start on your own. Finally, the postgraduate levels of academia create communities where immersion is possible, so that you acquire not only the ideas that are written down in books and papers but those that are communicated indirectly between experts in their fields.

Ultralearning isn't a rejection of those opportunities, and I would be disappointed if I were to be misread as arguing that they don't exist or are better replaced with a solitary learning effort. The correct mindset to cultivate isn't a rejection of anything slower or standardized but a recognition that the possibilities for learning anything are considerably broader than they might first appear.

Lifelong Learning

The goal of ultralearning is to expand the opportunities available to you, not narrow them. It is to create new avenues for learning and to push yourself to pursue them aggressively rather than timidly waiting by the sidelines. This is not going to be a method suitable for everyone, but for those who feel inspired to use it, I hope it provides a start.

Chapter 14: An Unconventional Education

Judit Polgár is widely considered to be the best female chess player of all time. At age seven, she won her first game against a chess master while blindfolded. At twelve, she was ranked fifty-fifth of all chess players in the world by the Fédération Internationale des échecs (FIDE) (World Chess Federation). By fifteen, she had become the youngest-ever grand master, beating the illustrious Bobby Fischer's previous record by one month. At her peak, Polgár was ranked eighth in the world and competed in the World Chess Championship, the only woman ever to have done so.

Chess is a game dominated by adult men. Thus a young girl competing was bound to arouse both the curiosity and the prejudice of her competitors. Grand master Edmar Mednis, facing off against the young Polgár, noted that he was very careful to play his best against the young prodigy, noting that "Grandmasters don't like to lose to 10-year-old girls, because then we make the front page of all the papers."¹ Some of her competitors celebrated the obvious genius of Polgár's play. Grand master Nigel Short said Polgár might be one of the "three or four great chess prodigies in history."² Mikhail Tal, a former world champion, suggested when Polgár was still twelve that she might eventually be a contender for world champion.

Garry Kasparov was less convinced. The former world champion has been considered by many to be the best chess player of all time. He is most famous for his matches against IBM's Deep Blue chess computer, winning against the machine in 1996 and losing in 1997, marking the transition to machine dominance in a game that had historically been considered one of the highest expressions of human creativity and intelligence. Kasparov was less than enthusiastic about the young Polgár's chances. "She has fantastic chess talent, but she is, after all, a woman. It all comes down to the imperfections of the feminine psyche. No woman can sustain a prolonged battle."³

That casual prejudice erupted into a full-blown controversy during their first match. Polgár, then only seventeen, sat across from the chess legend and former world champion, playing in a tournament in Linares, Spain. Although chess is often viewed as being coldly rational, as both players calculate moves with precision to reach their final outcome, the psychological effect of sitting opposite the dominant Russian can't be understated. Given that incredible tension, it was almost unbelievable when Kasparov, on move thirty-four, placed his knight and, after briefly lifting his fingers from the piece, changed his mind and moved it to a better square. Polgár was stunned. According to chess rules, once a player stops touching a piece, the move is done; no changes are allowed. Half in disbelief, she glanced at the referee, expecting him to indicate that Kasparov had cheated. Yet the referee didn't challenge the grand master. Reeling from the move, Polgár lost the game.

Asked why she hadn't challenged the illegal move herself, Polgár explained, "I was playing the World Champion and didn't want to cause unpleasantness during my first invitation to such an important event. I was also afraid that if my complaint was overruled I would be penalized on the clock when we were in time pressure."⁴ Still, after the game had concluded, she was incensed. She confronted Kasparov later in the hotel bar, demanding "How could you do this to me?"⁵ "She publicly accused me of cheating," Kasparov said when defending himself against the accusation. "I think a girl of her age should be taught some good manners."⁶ It would be years before

the two spoke again, but whereas Kasparov was already well established in the chess world, Polg r was just getting started.

Polg r is singular, not only for her prowess in the male-dominated game but also for how she learned to play. Unlike other famous players, such as Bobby Fischer, who spontaneously developed an obsession for the game, Polg r's chess genius was no accident. Instead, it started with one man's mission to raise genius children.

The Making of a Genius

Years before Judit faced down the legendary grand master, before her meteoric rise in chess or even her first game, her father, L szl Polg r, had made a decision: he was going to raise a genius. While studying intelligence in college, he had begun contemplating his project before having children or even a wife. "A genius is not born but educated and trained," he maintained. ⁷ Studying the biographies of hundreds of great intellectuals, he was convinced that genius could be manufactured. "[W]hen I looked at the stories of geniuses," he later remarked, "I found the same thing. . . . They all started at a young age and studied intensively." ⁸

But first, he had to find a partner for his pedagogical experiment. He found it in Kl ra, a Ukrainian foreign-language teacher. Far from your normal love letters, he first corresponded to her by explaining his idea to raise genius children. After agreeing to his proposal, the two met and were married in the Soviet Union before moving back to his native Hungary. Together the couple had three children, Zsuzsa, Zs fia, and Judit. Although Judit ended up becoming the most intensely competitive and famous, all three became world-class chess players, with Zsuzsa also becoming a grand master and Zs fia reaching the status of international master.

Living modestly in a cramped apartment, L szl and his wife decided to devote themselves full-time to their project of raising genius children. Their strategy was to begin the girls' educations early, at age three, and move on to specialization in one domain no later than six. They would start by introducing the girls to that subject slowly, in short bursts, and turn it into play so that they would actively want to practice rather than feel coerced into doing so. That strategy, however, didn't specify a topic. L szl and Kl ra considered many different possible study topics for their daughters, from foreign languages to mathematics. Eventually they settled on chess, because it was objective and progress in it was easy to measure. No doubt the preeminence of chess intellectually in the socialist countries in those years added weight to their decision to focus on the game.

Despite the emphasis on chess, L szl did not believe that such specialization needed to come at the sacrifice of the broader education of his girls. All three learned foreign languages (Zsuzsa, the eldest, learned eight), as well as mathematics, table tennis, swimming, and other subjects. The decision to focus on chess with all three girls was made for a practical reason: given the intense devotion both parents would need to have, in both resources and time, spreading their effort over three different disciplines would have been more than their budget or schedule could bear.

Zsuzsa was first to start. She began playing at age four. Six months later, she was going with her father to the smoke-filled chess clubs of Budapest, playing against elderly men—and winning. By the time it was Judit's turn, she was already motivated to begin her training. Zsuzsa and Zs fia played chess in a small room L szl had devoted to the game, and she didn't want to be left out.

Soon the three girls were a team, traveling around to compete against much older, usually male players. Their shared mission created camaraderie rather than jealousy in playing a game that very often pushed back against their unusual status. The Hungarian Chess Federation's policy was for women to compete in women-only chess events. However, L szl was strongly against the idea. "Women are able to achieve results similar, in fields of intellectual activities, to that of men," he felt. "Chess is a form of intellectual activity, so this applies to chess. Accordingly, we reject any kind of discrimination in this respect."⁹ Discrimination had already prevented Zsuzsa from obtaining the grand master title at fifteen. As the youngest, by the time Judit approached some of these barriers, her elder sisters had already broken them down a bit, allowing her to forgo competing in the women-only tournaments.

Although their education was the same and all three reached impressive heights in chess, the girls' prowess was not identical. Zs fia was the weakest of the three; although reaching the impressive grade of international master, she later decided to retire from chess to focus on art and her family. Zsuzsa had specialized a little less in chess from an early age, learning eight languages, which her father admits might have distracted her from reaching her maximum chess potential. Judit started more slowly, according to Zsuzsa, but she had the strongest work ethic, being "obsessed" with chess to a degree unusual even for her family.

Rematch with Kasparov

Eight years after her controversial defeat by Kasparov, Judit had another opportunity to face down the legendary grand master. In the 2002 Russia Versus the Rest of the World match in Moscow, Judit faced off against Kasparov in a game of rapid chess, with only twenty-five minutes allocated to each player. Judit played the Ruy Lopez, or Spanish game, named after the sixteenth-century Spanish bishop and chess strategist. This uses one of the most common openings in chess, moving the knight and bishop out to good squares on the second and third moves. Kasparov countered with the Berlin Defense, moving a second knight to the board while ignoring the potential danger created by his opponent's bishop; this was known to be a solid counter, often leading to draws. Kasparov wasn't taking any chances. After a flurry of exchanged pieces, both positions were quite close. Judit, as white, had castled her king into safety. Kasparov, as black, in losing the opportunity for the same safety had retained both the light-square and dark-square bishop pair, a powerful combination that can often be decisive in winning a game. Judit calmly pushed forward, cornering one of Kasparov's bishops and neutralizing his advantage. Slowly but surely, her moves continued to improve her position while Kasparov's looked increasingly questionable. Eventually, the small positional advantages Judit had accumulated over the midgame were threatening to win. Two pawns down and facing looming threats of checkmate, Kasparov resigned.

Following his defeat, Kasparov revised his earlier assessment of Judit's ability and indeed the idea of women competing against men at the highest levels of the game. "The Polg rs showed that there are no inherent limitations to their aptitude—an idea that many male players refused to accept until they had unceremoniously been crushed by a twelve-year-old with a ponytail."¹⁰

The Aftermath of an Experiment

L szl Polg r's conviction that he could turn any healthy child into a genius is the kind of assertion that would make him seem like a crackpot if he hadn't actually been successful. Nonetheless, a careful reader will note that, as far as

experiments go, L szl 's has plenty of holes that keep it from becoming a model of scientific purity. There was no control group, for starters. All three of the Polg r sisters received the same education. There was no fourth sister who went to school the normal way and missed L szl 's special training. There was no randomization. L szl didn't adopt a random child to raise in his unusual system but taught his own. This also means that the influence of genetics can't be ignored. The success of all three children may be owing to hereditary, rather than acquired, talents. There was also no blinding. All the Polg rs knew they were part of something special, a unique mission that set them apart from other families. Therefore, in the ongoing debate between nature and nurture, the success of the Polg r sisters might be suggestive of the role that unorthodox education can play, but it is far from definitive. Despite its failings as a purely scientific experiment, the Polg rs' work is certainly a window into what might be possible. All three girls achieved enormous results in chess. Although we cannot know for certain, it seems likely that they could have succeeded in any number of other domains as well. Similarly, although L szl 's methods were strange, it does not seem as though the girls suffered, either in their broader education or in their emotional well-being. They were self-confident and happy and grew up to be successful, emotionally stable adults with loving families of their own. When asked whether his strange pedagogical methods had robbed his girls of a normal childhood, L szl argued the opposite, that it is a normal, mediocre education that often leads to unhappiness. Interviewer Endre Farkas, who worked with Polg r on his book *Raise a Genius!*, asked, "Have they been educated too narrowly, deprived of a carefree childhood? I was able to observe the Polg rs. . . . One can clearly see that they are happy."¹¹

Educating Ultralearners?

Prior to doing the research for this book, all of the ultralearners I had met were ambitious self-starters. I was convinced that ultralearning was something that held great potential for the individual. However, owing to the intensity and commitment required by the learners themselves, I was skeptical that ultralearning would have any direct implications for the educational system at large. Children already struggle against onerous studying conditions, and it seemed to me that increasing the intensity of study would only increase their stress and anxiety.

Psychologists recognize a large difference between goals that people pursue intrinsically, based on their own interests, decisions, and targets, and goals that they pursue extrinsically, pushed by overbearing parents, punishing curricula, or demanding employers. The latter type, because the motivation for conforming to them comes primarily from outside social pressures, are the cause of much misery. Tales of depression, anxiety, and even suicide are distressingly common in environments where the pressure to perform on standardized tests is ratcheted up to an uncomfortable degree. Ultralearning, because it is a self-driven quest, not an externally imposed obligation, doesn't need to be this way. However, because of its very nature, it was unclear to me whether it was something that could be taught.

The Polg r sisters are an unusual case, then, because although they were trained from a very early age and worked incredibly hard, they don't seem to have been harmed psychologically by the pressure. In contrast to the stereotypical "tiger" parent, their parents encouraged their unusual specialization through play and positive feedback, not authority and punishment. The Polg r sisters all continued to play chess well into

adulthood at the competitive level. The obsession into chess, therefore, was clearly something fostered, rather than imposed. At the same time, their participation in the experiment wasn't exactly voluntary. L szl had dreamed up his goal of raising geniuses before knowing whether his children would consent to the program, so it was not a case of each daughter discovering for herself that she wanted to devote herself to an intense regimen of chess practice. That feature of the Polg r experiment interested me the most, because it seemed as if L szl and Kl ra had found a loophole in the normal expectation that pushing others to study intensely necessarily leads to misery.

How to Raise an Ultralearner

L szl Polg r wrote a book entitled *Raise a Genius!*, documenting his unorthodox approach to education.* In the book, he outlined his strategy for turning any normal, healthy child into a genius, provided the parents are willing to go to the extremes he and his wife dedicated to the task.

The first step is to start early. The child's education should begin no later than three, and specialization should begin no later than six. Although the exact extent to which learning becomes harder as we age is unclear, there is evidence from fields such as music and languages that children's brains are more plastic and flexible when younger. L szl took this idea to the extreme, encouraging training far earlier than is typical for early-childhood education.

The second step is to specialize. Although the Polg r sisters did learn languages, mathematics, sports, and other subjects, their focus was always on chess. L szl noted that "starting from 4–5 they played chess 5 or 6 hours a day."¹² That specialization seems to have had two roles in his strategy for raising geniuses. The first is that it took advantage of any hypothetical flexibility that younger children possess to learn new subjects easily. The second is that by specializing in one subject, the children could reach proficiency at a much younger age. Winning against older and more experienced opponents in chess built their confidence and competitive spirit, so that they actively wanted to practice more to improve themselves. Had the girls spread their intellectual appetites too broadly, they might not have developed the self-confidence that leads to intense practice.

The third step was to make practice into play. Chess, being a game, is naturally suited to play. However, L szl was insistent on introducing all subjects to the girls as forms of play. When the girls would become distracted or get up and wander around while playing a game, they weren't punished but encouraged to let their minds wander as they sought a solution. Keeping the game fun and light, especially when the children were young, was a key stepping-stone to developing the drive and self-confidence that would support more serious efforts later. However, it is important to keep in mind as L szl insisted that "play is not the opposite of work" and "a child does not need play separate from work, but meaningful action," adding "learning presents them with more enjoyment than a sterile game."¹³ Play and work combined in the Polg rs' approach to learning, with no rigid boundary between them.

Fourth, L szl was careful to create positive reinforcement to make chess a pleasant, rather than frustrating, experience. "Failure, suffering, and fearfulness decrease achievement. Following a number of successive failures, even a damaging inhibitory complex can be created," he explained.¹⁴ Starting with the behaviorists, psychologists have known in detail that having a positive experience, such as winning a game, can create a desire to repeat the behaviors that led to the experience. Negative experiences, from losing, becoming confused, or experiencing frustration against a stronger opponent

to facing an opponent who is too easy and robs the player of the satisfaction of pulling off an impressive victory, reduce enthusiasm. L szl carefully established the cycles of positive feedback early on. In the beginning, when he was still a stronger player than the girls, he would adjust his play so that they would be challenged but still win enough of the time to find the game enjoyable. “We should make sure not to always win against the child; we should let them win sometimes so that they feel they are also capable of thinking,” he wrote, adding “At the start it is most important to awake interest. . . . We should get the child to love what they do—to such a degree that they do it almost obsessively.”¹⁵

Finally, L szl was entirely against coercing learning. Self-discipline, motivation, and commitment, he felt, must come from the girls themselves. He explained, “One thing is certain: one can never achieve serious pedagogical results, especially at a high level, through coercion.”¹⁶ He also felt that “one of the most important educational tasks is to teach selfeducation.”

¹⁷ This final step of his process was particularly important for his daughters, as they quickly outpaced their father’s ability. Had they not been encouraged to develop their own abilities to teach themselves and adjust their learning, they might have become decent chess players but certainly not grand masters.

In addition to these basic principles, L szl and Kl ra devoted themselves intensely to providing every opportunity for the advancement of their daughters, cultivating a database of more than two hundred thousand matches, buying every chess textbook they could find, and recruiting chess tutors for their daughters. The girls lacked no opportunity to study and improve at the game. The Polg r house, with diagrams of chess positions hanging on the walls, became a temple devoted to the practice of the ancient game. For L szl and Kl ra, raising their children was more than a full-time job as they fostered the girls’ talents by both assembling resources and schooling them at home.

Ultralearning Principles in Action

In addition to Polg r’s principles of raising genius children, I found it interesting that all of the principles of ultralearning I’ve discussed this far were present in their approach to learning.

1. Metalearning

Polg r devoted himself full-time to understanding how people learn chess and under what conditions his daughters would thrive. He created a huge library of chess positions, strategies, and lists of games, which, in the days before widespread internet, was no small feat. He also articulated a plan for coaching the girls in the game when they were still very young, starting by teaching them first to name the squares on the board and later to know how the pieces moved. That slow progression allowed the girls to pick up the game even before their other cognitive abilities had developed.

2. Focus

L szl considered “the ability to handle monotony, the capability to sustain interest and persistent attention” as key traits he aimed to instill in his daughters. The girls twice took part in twenty-four-hour chess marathons when they were fifteen, nine, and eight years old, respectively, needing to complete one hundred matches in the time period. Chess is a game not merely of flickers of brilliance but of endurance and stamina. Training focus was a large part of L szl ’s system for his daughters, as he encouraged them to focus their minds on the problem and not get distracted.

3. Directness

L szl took his daughters to games with men when they were as young as four, showing them how the game was to be played against opponents who would really offer a challenge. The girls played many, many games of chess, which formed the backbone of their abilities. That allowed them to learn not only how to play the game well but also to deal with variables such as time pressure and the psychological insecurities of playing against older, more intimidating opponents. By using chess timers even for casual games, the girls practiced in an environment that more closely matched the one they would face in tournaments.

4. Drill

L szl varied the approaches to studying the game, starting his daughters off with memorizing first the names of the squares, then the movements of key pieces. Chess puzzles, hanging from the walls of the house, became the girls' homework, as they had to solve the different tactical positions and come up with creative solutions. Blitz and blindfolded games allowed the girls to get better at thinking more quickly and mentally simulating the game.

5. Retrieval

For retrieval, L szl explained, "We should not tell them everything; we should try to get the child to say something!" Using what he described as the "Socratic method" for chess, posing questions his girls must answer instead of telling them to remember a presolved solution, he was using the right method to encourage the expansion of their memory and understanding. Blindfolded games, once again, formed a powerful component of the girls' strategy. By practicing without looking at the board, it forced them to cultivate the ability to follow positions in their head, which was useful not only for retaining key chess patterns long term but also for honing the ability to simulate moves on the board that an opponent might play.

6. Feedback

L szl encouraged considerable play with real opponents but was careful to select "suitable partners, who have a generally similar playing ability." Interestingly, the feedback here was carefully controlled, not only to provide the girls with enough challenge (the Polg rs' insistence on playing in men's tournaments in order to face such a challenge was an example of this) but also to avoid too great a challenge when their abilities were still nascent. Cultivating positive feedback was important early on, and L szl was ever ready to adjust the flow of the game to make sure it was at a level that would stimulate further play.

7. Retention

L szl focused on having the girls recall chess patterns from memory and increased the speed of games to make elements of their play more automatic and less susceptible to forgetting. Memorizing chess patterns is a large part of playing the game successfully, and this was aided both by spaced practice and through specialized drills such as blitz and blindfolded games.

8. Intuition

Mirroring the Feynman Technique, L szl encouraged his girls to write articles about chess, explaining, "If one writes an article, one considers a matter more deeply than without a goal, thinking alone or speaking with someone about it." The girls were also encouraged to come up with creative solutions to problems. Play, not merely in the sense of chess being a game but also in the sense of an unconstructed, goalless activity, was part of the teaching strategy. Coming up with interesting solutions and challenging the

girls to think of tricks and new insights allowed them to explore outside what could be offered by memorizing past results.

9. Experimentation

As the Polg r sisters eclipsed their father in chess ability, their impetus to continue mastering the game increasingly had to come from within themselves. Each of the girls had to cultivate her own unique style and approach. Judit chose to focus on tricks and tactics, writing that “opening preparation was not at all important at that time. This may be a reason why, even today, my strongest area remains the middlegame.”¹⁸ The girls’ varying choices show that chess, like any creative skill, involves not merely a mastery of patterns but also choices about what skills and styles to cultivate within a vast range of possibilities.

Finally, the Polg rs embodied the idea of ultralearning at its broadest, with L szl arguing, “In my opinion, we should disseminate the idea of intensive learning in every field.” The success of the Polg rs follows the same pattern as that of most of the ultralearners I have met: aggressive, enthusiastic selfeducation following the key principles of learning.

Fostering Ultralearning in the Home, School, and Workplace

How can you foster ultralearning as a parent or educator or in an organization? Is it possible to help others self-confidently tackle difficult learning projects of their own design? Can you teach students not just the material they need to study but how to learn on their own, so they will be self-sufficient outside the classroom? Can you lead the individuals in your organization to learn more aggressively, filling gaps in their competency and achieving their full potential? These are all intriguing questions to which we don’t yet have definitive answers.

In reading the scientific literature on learning and following up with the ultralearners’ stories, I was struck not only by how much is known about learning already but by how many open questions exist for which researchers and autodidacts are still hazarding hypotheses. The complications expand exponentially once you introduce the social environment as well. Now it’s no longer a question simply of individual cognition but of the emotions, culture, and relationships that start to influence learning in complex and unexpected ways. From this perspective, therefore, I’d like to cautiously suggest some starting points for fostering an environment that will support ultralearning, at home, in the school, or in the workplace. These suggestions aren’t rules, but they can be seen as starting points for enabling others to capture the ultralearning spirit.

Suggestion 1: Create an Inspiring Goal

Better yet, allow people to design their own learning goals that inspire them. Inspiration is an essential starting point in the process of ultralearning. There must be something very compelling for a person to summon up the energy and self-discipline needed to learn. Sometimes that is the promise of a new skill bringing career opportunities. Coding boot camps, which have sprung up in the wake of high-paying programming jobs, push students through at a brutal pace, sometimes approaching eighty hours a week. The goal, however, is compelling enough to justify this investment: complete a rigorous program over the course of a few weeks, and you can rise up the ladder of high-salaried tech jobs in Silicon Valley and elsewhere. The process is intense, but the motive is compelling.

In other cases, the motivation for ultralearning comes from an intrinsic

interest that becomes amplified. My own MIT Challenge started with feeling I had missed out by not studying computer science in school. Normally, that wouldn't have led to any large, structured effort to learn a lot of computer science. It was only when the idea of doing an entire degree in a shortened period of time, along with the research that made me think it might be possible, that my initial interest become a passionate commitment. Roger Craig, with his Jeopardy! exploits, was always interested in trivia competitions. It was only when he recognized that there might be a chance to appear on the famous television show that his interest became an obsession. Eric Barone took his love of a childhood video game and expanded it into an effort to create a better version. Seeking out people's natural interests for ultralearning means encouraging the sparks that already exist, rather than merely imposing on them the topics you feel would be most beneficial. Once people see the structure of an ultralearning project, they can start thinking for themselves what would be most interesting, exciting, and useful for them to work on. Tristan de Montebello started with the idea of ultralearning and only later chose to craft a public speaking project around it.

Suggestion 2: Be Careful with Competition

The Polg rs' example clearly indicates that early self-confidence can create an enthusiasm that leads to continued investment. You don't need to feel as though you're good at something to invest energy into learning. After all, becoming good at something is what learning is. However, you need to feel that you could be good at it. People tend to make their perceptions of inadequacy into immutable destinies: "I'm no good at math," "I can't draw anything but stick figures," "I don't have the language gene." Although there likely do exist real differences in innate ability, so that these pronouncements aren't completely false, they tend to ignore an important factor: motivation. When you see yourself as lacking the potential to be good at something or believe that you'll always be behind everyone else no matter how hard you work, it robs you of the motivation to work hard. Thus, although there are differences in ability among all of us, they can often be exacerbated by the affective dimension they create in how we feel about learning. Feel as though you're lousy at doing something, and you're robbed of the motivation to change.

The reference group you compare yourself to can have a powerful influence. I find it interesting that many, but not all, ultralearners aimed at projects that were so unusual that they made it hard to compare them to a normal reference group. De Montebello's public speaking competition certainly pitted himself against excellent public speakers. That might have created a feeling of inferiority, except that de Montebello could always explain to himself any perceived deficits as coming from trying such an ambitious project with so little prior experience. Had it been the case that instead of an individual ultralearning project, he had been pitted against a dozen other competitors with exactly the same prior experience, he might instead have rationalized any perceived inadequacy as his simply not being good enough. This suggests that the competitiveness of the project cuts both ways: When you have a natural talent and thus perform much better than the easily identifiable reference group, you'll have more motivation to practice and learn with intensity. However, if you come up short, it may rob you of the motivation to practice. The Polg rs used competition to their advantage. Because the girls' training started unusually young, they were always seen as precocious and the competitive environment enhanced their motivation. Had

they started late or been put into a school where they weren't guaranteed to be star performers, their motivation might have been sapped.

To me, such motivational effects, coming from implicit comparison to a reference group, suggest adopting a twofold approach. If a person in whom you want to encourage an ultralearning spirit has a natural aptitude, competition is probably good. Seeing him- or herself do well in direct comparison with others may encourage a commitment to further improvement. For a person who either is of moderate ability or is behind other people, such as learning a skill in a domain in which he or she has no experience, or who is starting to learn a new skill later in life, you should make an effort to make the project unique. This will encourage the person to frame his or her progress by comparing to his or her past self, not due to competition with others. Sometimes a project can start out being unique, thus sheltered from the harsh light of unfavorable comparison, and move to a more competitive environment once confidence has been established. For example, you might start learning programming by creating a game that is hard to compare to others but enter coding competitions as you begin to feel more competent.

Suggestion 3: Make Learning a Priority

Outside school, learning is usually seen as a by-product of doing a job, not the core goal. Though organizations often give lip service to ongoing training and education, it's usually in the form of workshops or seminars that one sits through passively before getting back to the real job at hand. Ultralearning, by encouraging direct, intensive practice, provides the opportunity for a kind of fusion project—one that accomplishes real objectives but is also designed to teach something new.

The normal protocol for assigning a project is to find the best person for the job and give them the task. A learning-driven approach would suggest instead that people who are not yet capable of doing the task might be assigned to the project. An ultralearning-driven work environment might consist of employees' spending a majority of their time on projects that are within or near their competency levels but devoting a specific fraction of their time to working on projects that are a leap above their current abilities.

Although this is purely hypothetical, I imagine two benefits of this approach. First, it will create a culture of learning within an organization where people are always willing to try to solve problems they don't yet know how to solve, instead of expecting someone else to know the answer already. Second, it will help reveal talent by giving people challenges they can rise to. If mentorship opportunities and difficult projects are assigned only on a whim by managers, they will likely miss a lot of people who may have the ability to succeed in difficult positions but are never given the opportunity to do so.

At the highest levels, an ultralearning-driven culture also allows learning to go into areas where perhaps nobody else has a particular skill. Although going between established levels of skill is important, it is when one learns to do something that nobody else can do that learning becomes truly valuable.

Conclusion

In many ways, writing this book has been an ultralearning project. Although a writer researching for a book is hardly unique, not all ultralearning projects need to be one of a kind to matter to the person doing them. Sitting in my den at home are stacks of binders filled with thousands of pages of printed journal articles. My bookshelf now has dozens of obscure, out-of-print monographs on thin slices of the question of how people learn. Recordings of calls with

various researchers helped me realize how much nuance there is to even simple questions such as “Is feedback helpful?” and “Why do people forget?” I’ve poured over numerous biographies of famous intellectuals, entrepreneurs, and scientists to try to arrive at an understanding of how they approached learning. In many ways, the process of writing this book was a reflection of its subject—an ultralearning project to write a book about ultralearning. Although I had a strong interest in the subject of learning and had browsed textbooks, articles, and biographies before I began research into this book, it was only after I started this structured project that I really began to dig deep.

Beyond research, this book was a challenge for me as a writer. My writing experience comes from blogging, not authoring books. Striking the right tone in a book is hard, and it’s quite different from the casual daily missives in a blog. I knew from the start that I wanted to share the stories of others and their exploits, not just recount my own experiences. That was initially quite challenging. Most biographies and published stories don’t focus on learning methods. Even when learning is the central theme of the story, most biographers are satisfied to be in awe of talent, rather than dig into the specific details of how a person did a particular thing. My research efforts frequently involved scouring a five-hundred-page biography for the several paragraphs in which concrete details about learning methods were mentioned in passing. Although this created challenges, it also forced me to develop new skills as a writer. I had to improve my research and writing skills in ways that more than a decade of penning blog articles never had. Even the style of the book created a skill-challenging project for myself. I’ll leave it to you, the reader, to judge whether I was successful.

The metaproject of ultralearning to write a book about ultralearning also illustrates some important ideas. For one, although I’ve made enormous improvements in my writing ability and knowledge of cognitive science and stories of famous learning exploits, there is still far more to learn. Digging into the science, for instance, one can quickly develop a sense of vertigo standing atop the mountain of papers, theories, ideas, and experiments, all loosely connected to the topic of learning. Similarly, for every biography I read, there were hundreds I could not. For every ultralearning story I encountered, there were likely dozens more my searches didn’t reveal. It is a profound error to claim that learning is about replacing ignorance with understanding. Knowledge expands, but so does ignorance, as with a greater understanding of a subject also comes a greater appreciation for all the questions that remain unanswered.

In the face of this, one must simultaneously have confidence and deep humility. Without the belief that progress in one’s own knowledge and skill is possible, one cannot undertake the project required to generate it. This kind of confidence may be mistaken for arrogance by outsiders, as it can seem that an effort to learn something quickly and intensely is somehow an assertion that the subject is trivial or that, having learned something, one has learned everything. Instead, this confidence must be paired with deep humility. In every project I’ve undertaken, including this one, my thoughts upon concluding it were not to think I had finished but to suddenly become aware of how much further I could have gone. Before I started my MIT Challenge, I imagined that covering an undergraduate degree’s worth of computer science concepts would be plenty. After I had finished, I could see how each topic I had learned could be multiplied into a doctorate’s worth of research or a

lifetime spent coding to fully understand it. My experience in learning languages to a level where I could hold conversations made me realize how many more words, expressions, nuances of culture, and difficult communication situations were left to explore. Finishing a project, therefore, isn't usually accompanied by a sense of finishing learning but by the creation of a feeling of possibility as one's eyes are opened to all the things left to learn.

It's this aspect of learning that I find most interesting. Many pursuits in life have a kind of saturation point, after which the longing for more of a thing eventually diminishes as you get more of it. A hungry person can eat only so much food. A lonely person can have only so much companionship. Curiosity doesn't work this way. The more one learns, the greater the craving to learn more. The better one gets, the more one recognizes how much better one could become. If you finish reading this book and have been encouraged to try your own project, this would be my greatest hope—not that you'd be successful at your project but that your ending would be a beginning. That by opening a small crack in all the possibly knowable things there are in the world, you might peer through and find there is far, far more than you had ever imagined.

Step 194 - How To Become Straight A Student

Efficiency. The simple truth is that the brute force techniques used by most students are incredibly inefficient. When it comes to exam preparation, passive review is not an effective way to learn complicated concepts. It's also mentally draining, which further diminishes the rate at which you can absorb and internalize information. For paper writing, this same problem holds. When you approach the task without proper preparation, it becomes incredibly tiring and you can end up spinning your wheels. After a while, even the formation of coherent sentences becomes difficult and time intensive. In contrast, the techniques I came up with were so streamlined that I could learn more material than my classmates and actually spend less time studying. By eliminating stupid habits and wasted effort, I transformed exam prep and paper writing from a dreaded chore to a targeted activity. You will learn how to:

- Manage your time and deal with the urge to procrastinate.
- Take targeted notes in class.
- Handle reading assignments and problem sets with ease.
- Prepare efficiently for exams.
- Master the art of exam-taking.
- Write incisive critical analysis essays.
- Conduct thorough research.
- Write standout term papers.

A big part of the solution is timing—they gain efficiency by compressing work into focused bursts. To understand the power of this approach, consider the following simple formula:

work accomplished = time spent x intensity of focus

With this formula in mind, you can begin to understand why many straight-A students actually study less than their classmates: They replace long, low-intensity stretches of work with a small number of short, high intensity sessions. Of course, this is not the whole story behind their success; what straight-A students actually do in these short bursts is also crucial—technique is just as important as timing. Part Two (Quizzes and Exams) and Part Three (Essays and Papers) of this book are dedicated to these technical details. But learning how to follow an efficient schedule, and banishing pseudo-work from your college experience for good, is a crucial first step toward your academic overhaul.

Quizzes vs. Exams

If the test is worth less than 15 percent of your final grade, it's a quiz; otherwise, it's an exam. If the test is worth only 5 percent or less of your grade, designate this a tiny quiz. Don't spend too much time on tiny quizzes. Even if you fail one, it still probably won't change your final letter grade. And if you're attending classes and keeping up with your reading, you should be able to score above average with little to no preparation.

Step 1

Take Smart Notes

Gather the Right Materials When I was a freshman, less than half of my class brought a laptop to campus. The year I graduated, over 95 percent of incoming freshmen brought laptops. By the time you read this, laptops will more or less be the de facto standard for undergraduates across the country, and this is a great advancement for the cause of collegiate note-taking. Why? I think David, another Dartmouth student, put it best: "Use your laptop. Seriously! You will be overwhelmed by the quality and legibility of your notes... it's really a no-brainer."

Take Smart Notes in Nontechnical Courses (What's the Big Idea?)

The key to doing well in these courses is straightforward: Identify the big ideas. That's what it all comes down to. Exams in nontechnical courses focus entirely on big ideas—they require you to explain them, contrast them, and reevaluate them in the light of new evidence. If you are aware of, and understand, all of the big ideas presented in the course, these tasks are not so difficult, and strong grades will follow. As you would expect, lectures are a major source of these big ideas. Identifying them, however, is not a trivial task.

Professors ramble. And they rarely start a class by clearly identifying the big ideas that will be explored. Instead, they tend to dive right in, leaving the poor student to separate on his own the interesting conclusions from the digressions.

Format Your Notes Aggressively

When it comes to formatting the text itself, the basic rule to follow is that anything that makes the information easier to read is fair game. You don't need a consistent scheme. Don't be afraid to use aggressive text formatting to help emphasize important points. On a computer, smart students often make use of bold fonts and lists to help organize their thoughts. Capture Big Ideas by Using the Question/Evidence/Conclusion Structure Keep in mind that professors don't always state the question. Often they jump right into the evidence and leave it to you to deduce the question being discussed. Don't be afraid to jot down "QUESTION:" and then leave the rest of the line blank as you begin recording evidence. Once you figure out what the professor's talking about, you can go back and fill in this blank.

The same holds true for conclusions. Professors will sometimes hint at a conclusion but not come right out and present a neat endpoint for the current discussion. In this case, it will be up to you to synthesize the question, evidence, and professor's hints into a conclusion of your own. This is the important part. When you formulate a conclusion, you are cementing a big idea. If you can't finalize a conclusion before the professor moves on to the next question, simply jot down "CONCLUSION:" and plan to come back later during a lull in the lecture, or immediately following class, to fill in the blank.

Step 2

Demote Your Assignments

Work Constantly

Most college students depend on “day-before” assignment planning, meaning they never start an assignment until the day before it’s due. This might be the simplest scheduling decision, but it creates many problems. Large assignments will quickly transform from potentially interesting to tedious to painful when tackled in one monolithic, last-minute chunk of time. And, if two or more assignments happen to be due on the same day (which will happen often), you will be forced into a frenzied work marathon that will produce lackluster results at best. Smart students avoid these issues by working constantly on assignments, in small chunks, every day. “I try to sit down every Sunday night and plan out the week,” explains Simon, a straight-A student from Brown. “My goal is to make sure that I don’t have too much work on busy days and that I do at least a little bit each day.” For example, if you have a problem set due every week, complete one problem a day, one hour at a time. Don’t spend five hours the night before. The same goes for reading assignments—knock off a chapter a day, and you’ll never find yourself spending a lonely night with a textbook and a six-pack of Red Bull.

Bear in mind that even if you get caught up on all of your assignments for a given class, you should continue to work. For example, if it’s Sunday morning and you have already finished your reading for Monday’s history class, and you have time to spare, break out a book and do a little of the reading for Wednesday’s history class. This doesn’t mean that you should study like crazy twenty-four hours a day. Don’t stay up until 2 A.M. Sunday night trying to finish the entire week’s load. But on days where you happen to be ahead of schedule, and you have already put aside time to work on a certain class, take advantage of this fortuitous situation to get ahead. Once you get used to working a little bit every day, you’ll be surprised by how often this situation might arise.

Don't Read Everything

For example, in most college courses there are one or two sources that show up on the reading list for almost every lecture. We will call these favored sources— they're usually a textbook or a course reader, and they provide the basic structure for the course by outlining key facts and arguments in a condensed form. Always read the assignments from favored sources.

Professors usually augment these favored sources with a variety of supplemental readings that provide context or analyze certain arguments and events in more detail. These supplemental readings are often academic papers, transcripts of speeches, or chapters from books —and they are typically fascinating. But they are also typically expendable, and you should not plan on reading them all. Instead, if your time is limited during a particular week, then your strategy should be to select only the most important supplemental readings for review. So how do you decide which supplemental readings to review, which to skim, and which to skip? Straight-A students follow this simple hierarchy: Readings that make an argument are more important than readings that describe an event or person, which are more important than readings that only provide context (i.e., speech transcripts, press clippings).

Confirming Your Decisions

You should always use the lecture itself to confirm your choice about what to read and what to skip. If the professor emphasizes the importance of a work that you dismissed (which will happen occasionally—this system isn't perfect), then make a note that you will need to go back and cover this reading in more detail before the next exam. A smart technique is to simply write these skipped readings right onto your syllabus as an assignment for a later class. Choose a day with a light reading load, and treat the assignment as if it was given to you by your professor. If you don't explicitly schedule a time to cover this material, you will invariably procrastinate and then find yourself with a huge reading list to cover right before the exam.

Take Smart Notes on Your Favored

Reading Assignments

We've discussed which readings to ignore or skim. But the logical next question is what to do with the favored sources that you decide to read carefully. In this situation, how you take notes on the reading makes a big difference. If you write down very little, the assignment can be completed fast, but the time will be wasted because you won't have bothered to extract the big ideas in a way that makes them accessible when it comes time to study. If, on the other hand, you take detailed notes on every paragraph, your assignments will take way too long to complete. The best compromise is to use a strategy similar to the one outlined earlier for taking lecture notes. To refresh your memory, the core of this strategy is that all big ideas can be reduced to a question, evidence, and conclusion. This approach can work wonderfully for reading assignments as well. Apply it as follows:

First, as with lectures, try to take notes on your computer. They will be more organized and easier to computer. They will be more organized and easier to follow later on, when you use them for review. In addition, typing makes it easier to record more and finish faster. Next, carefully read the beginning of the assignment. Look for the question being answered by the author. Note that this is different than a thesis statement. For example, "Why did the Clinton health care plan fail?" is a question. "The Clinton health care plan failed because of resistance from commercial health care providers" is a thesis. In a reading assignment, the question can usually be found in the title or perhaps explained in the first few sentences. Record this in your notes, and label it clearly. Next, look for the

author's conclusion (the thesis statement). This is perhaps the most difficult part, since academics are known to propose complicated answers to their questions, especially when writing. So it may take some serious consideration to figure out what's being suggested. Search the first few paragraphs; this is typically where the conclusion is hidden. Also check the final few paragraphs. Often a thesis is proposed at the beginning of an article but then refined slightly at the end once all of the supporting evidence has been presented. When you feel confident in your understanding of the conclusion, record it carefully in your notes. Don't worry if it takes several sentences to capture the point—err on the side of being thorough. Now comes the easy part: Skim the entire reading. Now comes the easy part: Skim the entire reading. Don't take notes yet. Instead, use a pencil to make checkmarks next to important paragraphs that jump out at you. Because you are reading fast, you may miss some points—don't worry. "Just get the gist of the author's message and how he is supporting that message with evidence, then move on," explains Jason, a straight-A student from the University of Pennsylvania. You don't need to capture everything. Your goal is simply to mark a few solid examples that justify the conclusion as the answer to the question. Once you have skimmed through the entire reading, go back and find your check marks. For each mark, record in your notes a concise summary of the corresponding point. Label each point in your notes with the page number where you found it. This shouldn't take long. Don't worry about being formal or grammatically correct. Just dump these pieces of evidence into your notes. When you're done, your notes should contain a clearly labeled question followed by a half-dozen or so bullet-pointed pieces of evidence, then a clearly labeled conclusion.

Don't Work Alone on Problem Sets

Perhaps the most important rule for taming the problem sets assigned in technical courses is to follow our earlier rule and work on them constantly. As Ryan, a straight-A student from Dartmouth, explains: "You can work on problem sets in small pieces while you're between classes or activities." Concentrating on only one or two problems a day will help you avoid mental fatigue. Once your brain gets tired, it's easy to stall—but if you spread out your work, you will end up spending fewer hours on the assignment than if you tried to do it all at once.

Even with a smart schedule, however, you will probably still get stuck occasionally. When this happens, use all the available resources to help you get unstuck. If you're allowed to collaborate with your classmates, which is often the case in technical courses, definitely take advantage of this opportunity. As Greta from Dartmouth explains, working in groups "can drastically cut the time required to finish a really hard problem set." Identify one or two students who share a similar skill level. Identify one or two students who share a similar skill level as you and then construct a regular schedule for working together on the class assignments. Set your meeting dates for two or three days before the deadlines; this gives you time to first try the problems on your own and identify the ones that give you the most trouble. Then, when you meet with your problem set group, your energy will be focused where it's needed most. However, don't meet the day before your deadline. It's important to have at least one day before handing in the assignment so you can review all of your answers and fix any small mistakes. You should also take advantage of office hours. Most technical courses hold office hours once a week, usually run by a teaching assistant (TA). These meetings are meant to clarify complicated concepts from class and to be a source of help on hard problems. Always go to office hours, if you have time, and arrive knowing which homework problems pose the biggest challenge to you. Don't be afraid to ask for help. You will learn a lot during these weekly sessions, since the TAs will be able to walk you through the more difficult concepts—which will ultimately save you a lot of time and frustration.

Solve Problems on the Go

First, set aside a little block of time to familiarize yourself with a couple of problems, and make sure you understand exactly what is being asked. You may need to review your notes to refamiliarize yourself with the relevant concepts. Next, try to solve the problem in the most obvious way possible. This, of course, probably won't work, because most difficult problems are tricky by nature. By failing in this initial approach, however, you will have at least this initial approach, however, you will have at least identified what makes this problem hard. Now you are ready to try to come up with a real solution. The next step is counterintuitive. After you've primed the problem, put away your notes and move on to something else. Instead of trying to force a solution, think about the problem in between other activities. As you walk across campus, wait in line at the dining hall, or take a shower, bring up the problem in your head and start thinking through solutions. You might even want to go on a quiet hike or long car ride dedicated entirely to mulling over the question at hand.

Write Solutions Right the First Time

Another important time-saving tip for problem set work is to record solutions formally the first time you write them down. Many students first jot down their answers informally and then return later to reformat them into something neat enough for submission. There is no reason to include both steps. You are, for no good reason, adding a lot of extra time to the process. Instead, go slowly and deliberately the first time. Write your answer carefully, and clean it up immediately until it is of submission quality. Then you can cross the assignment off your list and it will be one less thing to worry about.

Step 3

Marshal Your Resources

Smart students understand that if you're studying hard, then you've done something wrong. Preparing for a test should not be painful. And it should not require a lot of time. If you have been putting Steps #1 and #2 into practice, taking smart notes and handling assignments effectively, studying should not be a big deal for you either. In fact, when faced with a looming quiz or exam, you have to do only two things. First, organize your material intelligently. Second, perform a targeted review of this material. This section will teach you how to accomplish the former. Don't worry—organizing your material properly is not a difficult task, but it is important that you do it right. Many students neglect this step, eager to dive right into the review, but by doing so they condemn themselves to hours of unnecessary work. You don't want to be like these students. Pay attention to the advice that follows and you will experience a significant reduction to the difficulty of your study experience.

Define the Challenge

Before you can conduct any meaningful studying, you must first define the scope of the exam. As Simon from Brown puts it: "You need to know what kind of information the professor wants you to know." To accomplish this goal, answer the following questions:

- Which lectures and reading assignments (or problem sets) are fair game?
- What type of questions will there be, and how many of each? As Christine from Harvard explains: "It's helpful to know in advance what kind of knowledge will be asked for on the exam—IDs, dates, broad syntheses of the texts' major arguments?"
- Is the exam open note or open book?
- For a technical class, will formulas be provided or do they need to be memorized?
- How much time will be available? Does the professor expect the exam to be easy to complete during the test period or a challenge?

Some professors offer answers to these questions without being prompted. Many, however, do not. If it's two weeks before the exam, and the professor hasn't mentioned any details yet, you should ask. If you're shy, ask after class. But get the information as early as possible—it's crucial to your success. Build a Study Guide (Organizing Nontechnical Course Material) "I have always been a big fan of making a study guide," admits Ryan from Dartmouth. This is a technique that popped up again and again in my

straight-A interviews. Each student, of course, had his or her own variation on study guide creation, but they all followed, more or less, this same general approach:

For a nontechnical course, once you find out which lectures and reading assignments are fair game for the exam, print out the corresponding notes that you've typed up or gather the pages you've written on (don't be afraid to deconstruct your notebook). Cluster these pages into piles, separated by general topic. Clearly label each of these piles with its topic and fasten them together with a paper clip so you can easily transport them without mixing up the pages. This final step is important, since you will be moving to and from your various isolated study spaces once you begin your review. For simplicity, we will refer to these topic-themed piles as "chapters." Your final study guide, therefore, should contain a chapter, consisting of reading and lecture notes, for each general topic that might be covered on the exam.

Construct a Mega-Problem Set (Organizing Technical Course Material)

For a technical course, many students follow a variant of the study guide approach that focuses on sample problems. It works as follows: Your problem set assignments are the key to your review process. Start a pile for each problem set that covers material that might appear on the exam. Next, you'll need to supplement each problem set with sample problems from your lecture notes. For each lecture relevant to the upcoming exam, do the following:

1. Match the lecture to the problem set that covers the same material.
2. Copy sample problems from these lecture notes onto a blank sheet of paper. You don't have to copy the steps or the answers, just the questions.
3. Label the blank sheet of paper with the date of the lecture. This will help you later figure out where these problems came from (and more important, where their answers can be found).
4. Fasten this sheet with a paper clip to the problem set you matched it to in step one. In other words, this process transforms your problem sets into mega-problem sets by adding extra problems drawn from your lecture notes. Pretty simple.

Finally, you must augment your mega-problem sets with technical explanation questions. What are these?

For every major topic covered in a particular megaproblem set, jot down a question that asks you to explain the basics of the topic. For example, as Greta from Dartmouth recounts, in an “economics course, I would make study sheets and then add a general question such as: what happens when a government increases spending and lowers interest rates?” Or, for a chemistry class, you might have a problem set containing many questions that require you to draw the molecular structure of specific chemical compounds. In this case, you could add a technical explanation question along the lines of: “Explain the general procedure for drawing a molecular structure, why this is useful, and what special cases must be kept in mind.” It’s important that you add these technical explanation questions in addition to your regular sample problems, since they will reveal whether or not you understand the underlying concepts or if you’ve just memorized the steps for some particular problems. One last note: If your professor makes a practice exam available, then print out a copy of it and store it with your mega-problem sets. For technical courses, sample exams are a great review tool, and you will definitely want to have them handy when it comes time to study.

Prepare Memorization Aids

Both technical and nontechnical courses sometimes require you to do some memorization—formulas, chemical equations, artwork, dates, or chronologies—and the most efficient way to memorize this information is by using flash cards. Almost every straight-A student interviewed for this book used flash cards to help with rote memorization. Fortunately, this technique is easy. Buy a stack of index cards, put the prompt on one side and the answer on the other. Constructing these flash cards, however, can take longer than you might imagine, so start early. If possible, start writing up your cards at least a week before the first day you plan to actually study. The activity is mindless—you can write flash cards while watching TV—so it shouldn’t be too hard to get them done, in advance, bit by bit.

Schedule Your Organization Wisely

Don't try to organize and study in the same day. This is a crucial tactic used by many straight-A students. When you review, you want your brain at full power. If you organize your materials the same day that you review them, your brain will be too tired to accomplish both effectively. So keep these two tasks separate and you'll end up working more effectively, which reduces the total time spent and produces better results.

Step 4 Conquer the Material

This is the step students most commonly identify with exam preparation. It's also the step that most students misguidedly spend the majority of their time on. You're not most students—at least not anymore. All of the work you put in up to this point was meant to make this one step as small and painless and insignificant as possible. So don't worry. There are no all-nighters in your future. What follows are powerful techniques for taking your imposing piles of study material and imprinting the key ideas on your mind as efficiently as possible. These techniques are quick but ruthlessly effective. Use them with confidence. They get the job done, and they get it done fast.

1. James March: The Ambiguities of Experience

How do our experiences help us learn? We're often told that experience is the best way to learn. We might see this play out when someone gives us advice which we ignore, until experience teaches us the same lesson.

In his book, The Ambiguities of Experience, James March explores the role of experience in creating intelligence.

Our attitudes to experience can be mixed. On the one hand, we often describe it as the ultimate teacher. On the other hand, we assume those who need to learn from it, instead of the wisdom of others, are not the smartest. After all, why learn everything yourself when you can just listen to others?

It's clear that there's a disconnect between our different attitudes to learning from experience.

"Since experience in organizations often suffers from weak signals, substantial noise, and small samples, it is quite likely that realized history will deviate considerably from underlying reality."

— James March

Individuals and organizations are often eager to learn from their experiences. But the inferences they make are often misguided. The properties of experience confound learning. 'Experience,' March concludes, 'may possibly be the best teacher, but it is not a particularly good teacher.'

Here are some of my notes from the book:

- Intelligence normally entails two interrelated but somewhat different components. The first involves effective adaptation to an environment. The second: the elegance of interpretations of the experiences of life.
- Since experience in organizations often suffers from weak signals, substantial noise, and small samples, it is quite likely that realized history will deviate considerably from the underlying reality.
- Agencies write standards because experience can be a poor teacher.
- Constant exposure to danger without its realization leaves human beings less concerned about what once terrified them, and therefore experience can have the paradoxical effect of having people learn to feel more immune than they should to the unlikely dangers that surround them.
- Generating an explanation of history involves transforming the ambiguities and complexities of experience into a form that is elaborate enough to elicit interest, simple enough to be understood, and credible enough to be accepted. The art of storytelling involves a delicate balancing of those three criteria
- Humans have limited capabilities to store and recall history. They are sensitive to reconstructed memories that serve current beliefs and desires. They conserve belief by being less critical of evidence that seems to confirm prior beliefs than of evidence that seems to disconfirm them. They destroy both observations and beliefs in order to make them consistent. They prefer simple causalities, ideas that place causes and effects close to one another and that match big effects with big causes.
- The key effort is to link experience with a pre-existent accepted storyline so as to achieve a subjective sense of the understanding.
- Experience is rooted in a complicated causal system that can be described adequately only by a description that is too complex for the human mind. The more accurately reality is reflected, the less comprehensible the story, and the more comprehensible the story, the less realistic it is.

- Storytellers have their individual sources and biases, but they have to gain acceptance of their stories by catering to their audiences.
- Despite the complications in extracting reality from experience, or perhaps because of them, there is a tendency for the themes of stories of management to converge over time.
- Organizational stories and models are built particularly around four main mythic themes: rationality (the idea that the human spirit finds definitive expression through taking and justifying action in terms of its future consequences for prior values); hierarchy (the ideas that problems and actions can be decomposed into nested sets of subproblems and sub-actions such that interactions among them can be organized within a hierarchy); individual leader significance (the idea that any story of history must be related to a human project in order to be meaningful and that organizational human history is produced by the intentions of specific human leaders); and historical efficiency (the idea that history follows a path leading to a unique equilibrium defined by antecedent conditions and produced by competition).
- Underlying many of these myths is a grand myth of human significance: the idea that humans can, through their individual and collective intelligence actions, influence the course of history to their advantage.
- The myth of human significance produces the cruelties and generosityes stemming from the human inclination to assign credit and blame for events to human intention.
- There is an overwhelming tendency in American life to lionize or pillory the people who stand at the helms of our large institutions -to offer praise or level blame for outcomes over which they may have little control.
- An experienced scholar is less inclined to claim originality than is a beginner.
- ...processes of adaptation can eliminate sources of error but are inefficient in doing so.
- Knowledge is lost through turnover, forgetting, and misfiling, which assure that at any point there is considerable ignorance. Something that was once known is no longer known. In addition, knowledge is lost through its incomplete accessibility.
- A history of success leads managers to a systematic overestimation of the prospects for success in novel endeavors. If managers attribute their success to talent when they are, in fact, a joint consequence of talent and good fortune, successful managers will come to believe that they have capabilities for beating the odds in the future as they apparently have had in the past.
- In a competitive world of promises, winning projects are systematically projects in which hopes exceed reality
- The history of organizations cycling between centralization and decentralization is a tribute, in part, to the engineering difficulty of finding an enduring balance between the short-run and local costs and the long-run and more global benefits of boundaries.
- The vividness of direct experience leads learners to exaggerate the information content of personal experience relative to other information.
- The ambiguities of experience take many forms but can be summarized in terms of five attributes: 1) the causal structure of experience is complex; 2) experience is noisy; 3) history includes numerous examples of endogeneity, causes in which the properties of the world are affected by actions adapting to it; 4) history as it is known is constructed by participants and observers; 5) history is miserly in providing experience. It offers only small samples and thus large sampling error in the inferences formed.
- Experience often appears to increase significantly the confidence of successful managers in their capabilities without greatly expanding their understanding.

2. Donald Norman on the Two Types of Knowledge

An interesting excerpt from Donald Norman's book The Design of Everyday Things on two types of knowledge.

People function through their use of two kinds of knowledge: knowledge of and knowledge how.

...Knowledge how [is] what psychologists call procedural knowledge.

...Procedural knowledge is difficult or impossible to write down and difficult to teach. It is best taught by demonstration and best learned through practice. Even the best teachers cannot usually describe what they are doing. Procedural knowledge is largely subconscious.

In a way, Norman's quote reminds me of this excerpt from Matthew Crawford's Shop Class as Soulcraft: An Inquiry into the Value of Work on thinking by doing.

The current educational regime is based on a certain view about what kind of knowledge is important: "knowing that," as opposed to "knowing how." This corresponds roughly to universal knowledge versus the kind that comes from individual experience. If you know that something is the case, then this proposition can be stated from anywhere. In fact such knowledge aspires to a view from nowhere. That is, it aspires to a view that gets at the true nature of things because it isn't conditioned by the circumstances of the viewer. It can be transmitted through speech or writing without loss of meaning, and expounded by a generic self that need not have any prerequisite experiences. Occupations based on universal, propositional knowledge are more prestigious, but they are also the kind that face competition from the whole world as book learning becomes more widely disseminated in the global economy. Practical know-how, on the other hand, is always tied to the experience of a particular person. It can't be downloaded, it can only be lived.

Some incomplete thoughts:

Knowledge of is knowing some fact. The world is full of people who 'know' stuff. These are the people that can recite facts. They know what something is called. They know the ten ways to write. They know calculus. But they often have difficulty understanding these things at a deeper level. Often, they are domain dependent. That is, they know something only in the context in which they learned it and experience difficulty applying it outside of that context.

We often end up knowing what something is called without really understanding. This is the illusion of knowledge.

The famous physicist Richard Feynman expands on the difference between knowing the name of something and knowing something.

As Charlie Munger says "You may have noticed students who just try to remember and pound back what is remembered. Well, they fail in school and in life. You've got to hang experience on a latticework of models in your head."

3. Alignment: The Key to Success Nobody Ever Taught You

I spend a lot of time thinking about this simple idea: The person who aligns themselves with the general principles of the world goes further and faster than the person who doesn't.

What the pupil must learn, if he learns anything at all, is that the world will do most of the work for you, provided you cooperate with it by identifying how it really works and aligning with those realities. If we do not let the world teach us, it teaches us a lesson.

— Joseph Tussman

The way to align yourself with the world is to take simple ideas seriously.

Consider compounding.

We know that spending less than we make, investing the difference in index funds, and waiting for a long time creates financial independence. Yet how many people follow this principle? Not many. Most of us know what works but fail to align ourselves with it.

Compounding applies to relationships too. Not just with your partner, but with your colleagues, friends, and even your customers. For relationships to compound, they must be win-win. But how many people take a consistent win-win approach? Not many. Again, we know what works, but fail to align ourselves with it.

Outcome over Ego

Here's the trick to seeing things differently: put your energy into *being* right, not *feeling* right. While that sounds simple, it's far from easy.

If you want to be right, you have to change your mind. When the evidence indicates the approach isn't working, change the approach. This is easy with something like math, where the answers are black and white, but harder with more subjective things.

Often the hardest things to change our minds about are the things that require us to understand that just because we can't see the results immediately doesn't mean they are not moving us closer or further from the outcome we want. For instance, eating a full pizza once won't make you unhealthy, but repeating that choice daily for years certainly will.

Feeling right, on the other hand, often requires you to believe you are an exception. You know the path to financial independence, but that takes too long. It's boring. Instead, you'd rather try the latest incarnation of a get-rich-quicker scheme that promises the outcome sooner. When it inevitably fails to produce the desired results, rather than tell yourself you made a mistake you chalk it up to the world not working as it should. It's as if that little voice in your head says, "You're not wrong; the world is."

Most of us would rather bargain with how the world works than accept how it does work, cooperate with it, and move forward. This happens in a lot of areas of life. Consider the general concept of health.

A lot of people think they don't have to take care of their health. They get too little sleep. They drink too much. They eat incredible amounts of processed food. They get little to no exercise. While they know health is important, at some level they think they are the exception. Acceptance is knowing you must care for your health because it is the foundation for everything else. Without health, everything else multiplies by zero.

We are tempted to believe we're the exception because it's the easy path.

Aligning with the world often requires you to pre-pay now for a result later. A little bit of pain today for gain tomorrow. And we don't like the sounds of that.

However, if you can align yourself with the world despite what those around you do, you'll quickly discover that it tends to do most of the work for you. It just won't take the first step for you. You have to take that one for yourself.

4. Learning Effectively From Experience: Distinguishing High from Low Performers

High performers learn from both success and failure making small adjustments.

Conversely, low performers learned more from success.

Learning effectively from experience is a daunting task for any organism. For every good or bad outcome, there are an immense number of potential causes and associations to be considered. For many decisions, it can be nearly impossible to pick out the few relevant factors from the many irrelevant factors, even with extensive experience. A major stumbling block for learning in these multi-dimensional environments is the tendency to form spurious beliefs: i.e., to attribute a causal role to factors that have no actual bearing on the outcome.

The formation of spurious beliefs is universal, from Skinner's observations of superstitious pigeons [1] to an athlete's belief in a lucky hat. In some situations, these beliefs are essentially harmless; by-products of learning mechanisms, but in other settings their impact can be severe. For example, spurious associations can have literal life-or-death consequences when they affect the complex decisions made by physicians. These expert decision-makers must extract and distill relevant features from a myriad of tests, symptoms, and personal histories, and employ these features to make critical medical decisions. Consequently, it is important to understand how spurious associations form and how they can bias subsequent decisions.

Spurious learning and false belief formation happens when the dorsolateral prefrontal cortex fails to distinguish correctly between important and unimportant associations.

The authors conclude:

High performers learned from both successes and failures, and made smaller rule adjustments after feedback. Conversely, low performers learned disproportionately from successes, and made larger rule adjustments ...

Taken together, the behavioral and neuroimaging results suggest that success-chasing and confirmation bias may underlie the relative pervasiveness of premature, asymmetric learning and the resultant poor performance of the majority of physician subjects in the present study. The general human bias towards confirmation over disconfirmation in hypothesis-testing has been extensively documented in a variety of non-medical contexts, such as the Wason Card Task. Conversely, the necessity for disconfirmation learning in empirical investigations is a key principle identified by the philosopher of science, Karl Popper [28]. Conceivably, providing medical professionals with formal training in disconfirmation learning could improve their ability to learn effectively from clinical experience in real-world settings. Exploring this possibility would be an important area for future research.

In conclusion, the results of this study show distinct patterns of learning, both behaviorally and neurally, between effective and ineffective learners among physicians making decisions in a medically framed learning task. The tendency to chase successes and ignore failures provides a simple computational model of how spurious beliefs might be formed, and how different individuals seeing similar data might learn very different sets of associations. The neural differences observed could conceivably be developed into useful biomarkers for essential differences in individual learning styles. These may in turn prove useful in identifying those individuals who can resist the impulse to chase successes, and hence learn most effectively from experience. Finally, we note that although this study focused upon the specific case of medical decision-making, the findings may be also be relevant to many other fields in which experts must make high-stakes decisions by drawing upon personal experience.

Abstract:

Accurate associative learning is often hindered by confirmation bias and success-chasing, which together can conspire to produce or solidify false beliefs in the decision-maker. We performed functional magnetic resonance imaging in 35 experienced physicians, while they learned to choose between two treatments in a series of virtual patient encounters. We estimated a learning model for each subject based on their observed behavior and this model divided clearly into high performers and low performers. The high performers showed small, but equal learning rates for both successes (positive outcomes) and failures (no response to the drug). In contrast, low performers showed very large and asymmetric learning rates, learning significantly more from successes than failures; a tendency that led to sub-optimal treatment choices. Consistently with these behavioral findings, high performers showed larger, more sustained BOLD responses to failed vs. successful outcomes in the dorsolateral prefrontal cortex and inferior parietal lobule while low performers displayed the opposite response profile. Furthermore, participants' learning asymmetry correlated with anticipatory activation in the nucleus accumbens at trial onset, well before outcome presentation. Subjects with anticipatory activation in the nucleus accumbens showed more success-chasing during learning. These results suggest that high performers' brains achieve better outcomes by attending to informative failures during training, rather than chasing the reward value of successes. The differential brain activations between high and low performers could potentially be developed into biomarkers to identify efficient learners on novel decision tasks, in medical or other contexts.

5. Does Experience Make You an Expert?

In Experience and validity of clinical judgment: The illusory correlation, Robyn Dawes explores the relationship between experience and accuracy.

There is research about the relationship between experience and diagnostic and predictive accuracy, and about the validity of interviewing people to find out what they are like. Garb has recently summarized the research on experience and accuracy. There is no relationship between years of clinical experience and accuracy of judgment. A report of a task force of the American Psychological Association convened in the early 1980s noted that there was no evidence that professional competence is related to years of professional experience.

And yet we seek experienced people to be our teachers, executives, and political leaders. Ben Franklin is oft quoted as saying “experience is the best teacher,” the second clause reads “and fools will learn from no other.” Only Franklin didn’t say “the best teacher” he said “dear teacher,” which was clearly intended to mean expensive.

The 10,000-hour rule, popularized by Malcolm Gladwell and based on Anders Ericsson’s study, *The Role of Deliberate Practice in the Acquisition of Expert Performance*, states that in order to become an expert, one must have 10,000 hours of deliberate practice under their belts. This has been highly disputed by many, including Ericsson himself. There’s no question that practice is necessary for improvement, but 10,000 hours isn’t a magic number that wields the power of universal application.

Something else to ponder: why is it that we often forget to account for the length of time that an expert has been out of practice in their field?

So does experience really make you an expert? What does it actually mean to be one? It turns out, we don’t learn from experience in many contexts.

The analysis of what we learn and why we learn it, however, quickly yields sobriety about embracing generalizations about the effect of experience on learning across all contexts. For example, learning to sit in a chair, become a chess grandmaster, make a correct medical diagnosis, or avoid a war are quite different processes. The word “learning” is, of course, common to all, but close examination reveals that it means little more than that someone with no experience whatsoever could not accomplish any of these tasks.

Dawes illuminates this highly contrarian idea through quite unremarkable human behaviours like sitting in a chair and driving.

What then are the differences? First, consider sitting in a chair. It is a motor skill. It is done automatically. It does not involve any conscious hypotheses. It is clearly learned through early experience that provides immediate feedback about failure. Finally, it is not taught in the sense that one person conveys a verbal or mathematical description to another about how to do it. (In fact an amusing exercise is to attempt to write such a description, convince somebody else to follow your instructions explicitly—and then watch the person fail.) Driving a car has many similar characteristics. For example, steering it in a straight line is accomplished by very tiny discrete adjustments of the steering wheel that are not accomplished consciously (Ehrlich, 1966). (The “weaving” behavior of drunk drivers is often due to the impairment of these movements, rather than to any visual problem.) The skills needed to perform these slight movements are attained only through experience driving; in fact, most complete novices on the first driving lesson alternate between going toward the ditch and almost crossing the center line—much to the surprise and consternation of their novice teachers, who themselves may be unaware of their own “tremorous” movements of the steering wheel. As with sitting in a chair, explicit verbal instructions to someone else about exactly how to drive a car could result in disaster for the person who follows them rigidly.

Consider the curious thing that happened during the Paris Wine Tasting of 1976, alternatively known as the Judgement of Paris (its name was inspired by a story in Greek mythology). During this blind taste competition, French wine experts judged ten different reds and ten different whites. Contrary to the strongly held belief that France produced the finest wines, it was the California wines that received the highest scores. Not only did the shocking results of the competition call into question the supposed superiority of French wine, but it served as a reason for people to wonder what authority an expert had over a casual wine drinker.

Abstract of Experience and validity of clinical judgment: The illusory correlation
Mental health experts often justify diagnostic and predictive judgments on the basis of "years of experience" with a particular type of person. Justification by experience is common in legal settings, and can have profound consequences for the person about whom such judgments are made. However, research shows that the validity of clinical judgment and amount of clinical experience are unrelated. The role of experience in learning varies as a function of what is to be learned. Experiments show that learning conceptual categories depends upon: (1) the learner's having clear hypotheses about the possible rule for category membership prior to receiving feedback about which instances belong to the category, and, (2) the systematic nature of such feedback, especially about erroneous categorizations. Since neither of these conditions is satisfied in clinical contexts in psychology, the subsequent failure of experience per se to enhance diagnostic or predictive validity is unsurprising. Claims that "I can tell on the basis of my experience with people of a particular type (e.g., child abusers) that this person is of that type (e.g., a child abuser)" are simply invalid.

6. Become A Learning Machine

When successful people from different fields offer the same advice, I listen. Often they have different vocabulary around an idea, but when you break it down you realize they're talking about the same thing.

Below is an example of Charlie Munger, Carol Dweck, and Susan Cain, offering the same core advice: Become a Learning Machine.

If you want to go to bed smarter than you woke up, you need to learn something new each day. It doesn't matter how smart you are today; what matters it that you learn something new and useful. If you can simply repeat that day after day, you will find that you outperform others.

It can be hard to grasp this concept because the differences at first are small. Only as the days turn into weeks, the weeks into months, the months into years, and the years into decades will you look back and wonder how it happened.

Charlie Munger:

I constantly see people rise in life who are not the smartest, sometimes not even the most diligent, but they are learning machines. They go to bed every night a little wiser than they were when they got up and boy does that help, particularly when you have a long run ahead of you.

Carol Dweck says:

You have to apply yourself each day to becoming a little better. By applying yourself to the task of becoming a little better each and every day over a period of time, you will become a lot better.

And this tidbit from Susan Cain, also fits:

...identify the tasks or knowledge that are just out of your reach, strive to upgrade your performance, monitor your progress, and revise accordingly.

7. The Feynman Technique: Master the Art of Learning

The Feynman Technique is the most effective method to unlock your potential and develop a deep understanding.

Richard Feynman was not only a Nobel laureate in Physics but also a master of demystifying complex topics. His key learning insight: complexity and jargon often mask a lack of understanding.

Feynman's learning technique comprises four key steps:

1. Select a concept to learn.
2. Teach it to a child.
3. Review and refine your understanding.
4. Organize your notes and revisit them regularly.

Let's delve deeper into these steps.

Feynman's secret lay in understanding the true essence of a concept rather than merely knowing its name, leading to his remarkable achievements. This learning technique can be applied universally, irrespective of the subject.

The person who says he knows what he thinks but cannot express it usually does not know what he thinks.

Mortimer Adler

Step 1: Select a concept to learn.

What topic are you curious about?

Take out a blank sheet of paper. Write out everything you already know about the subject you want to understand deeper. As you learn more about the topic, add it to your sheet. If you use a different color pen as you learn new things, you can literally watch your knowledge grow.

Once you think you understand the topic well enough, move on to step 2.

Step 2: Teach it to a child.

Can you explain your chosen concept to a 12-year-old? Test your understanding by simplifying your notes. Banish jargon and complexity, using only words a child would

comprehend. Simplicity reveals a depth of understanding, while jargon often conceals ignorance.

Anyone can make a subject complicated but only someone who understands can make it simple.

Step 3: Review and Refine

Write down your simplified explanation. The act of writing aids reflection and learning. In fact, reflection is the most important part of the learning process. Reflection is how we learn what we know and what we need to learn.

Simple is beautiful.

Clear writing gives poor thinking nowhere to hide.

Ensure your notes are free of any jargon or something that sounds confusing. Ensure your notes are free from jargon or any glossed-over complexities. If something sounds confusing, it needs more refinement.

Read it out loud as if to a child. If the explanation isn't simple enough or sounds confusing, that's a good indication that you need to reflect and refine.

Go back to the source material, reviewing the parts you don't quite understand yet.

Repeat until you have a simple explanation.

Step 4: Organize and Review.

To test your understanding in the real world, present your explanation to someone else.

How effective was your explanation? What questions did they ask? What parts did they get confused about?

When you're happy with your understanding, take the page you created with a simple explanation and put it into a binder. Following this technique for everything you learn gives you a binder full of learning that you can review a couple of times a year.

Simplicity is the hallmark of true understanding. Challenge others who use jargon to explain concepts in simple terms, and their reactions may reveal their comprehension (or lack thereof).

The Feynman Technique is the foundation for our 'blank sheet' approach to supercharging your reading and retention.

8. The Learning Paradox: Why Struggling to Learn is a Good Thing

The more you struggle to master new information, the better you'll understand and apply it later.

Annie Murphy Paul explores in Time:

The learning paradox is at the heart of “productive failure,” a phenomenon identified by Manu Kapur, a researcher at the Learning Sciences Lab at the National Institute of Education of Singapore. Kapur points out that while the model adopted by many teachers and employers when introducing others to new knowledge — providing lots of structure and guidance early on, until the students or workers show that they can do it on their own — makes intuitive sense, it may not be the best way to promote learning. Rather, it’s better to let the neophytes wrestle with the material on their own for a while, refraining from giving them any assistance at the start

Earlier this year, in a paper published in the Journal of the Learning Sciences, Kapur applied the principle of productive failure to mathematical problem-solving.

With one group of students, the teacher provided strong “scaffolding” — instructional support — and feedback. With the teacher’s help, these pupils were able to find the answers to their set of problems. Meanwhile, a second group was directed to solve the same problems by collaborating with one another, absent any prompts from their instructor. These students weren’t able to complete the problems correctly. But in the course of trying to do so, they generated a lot of ideas about the nature of the problems and about what potential solutions would look like. And when the two groups were tested on what they’d learned, the second group “significantly outperformed” the first.

The apparent struggles of the floundering group have what Kapur calls a “hidden efficacy”: they lead people to understand the deep structure of problems, not simply their correct solutions. When these students encounter a new problem of the same type on a test, they’re able to transfer the knowledge they’ve gathered more effectively than those who were the passive recipients of someone else’s expertise.

Kapur argues we need to “design for productive failure” by building it into the learning process.

In the process of his work he’s identified three conditions that promote a beneficial struggle:

1. Choose problems that “challenge but do not frustrate.”
2. Allow students to explain and elaborate on what they’re doing.
3. Compare and contrast both good and bad solutions to the problems.

9. Ten Commandments For Living From Philosopher Bertrand Russell

Philosopher Bertrand Russell:

The Ten Commandments that, as a teacher, I should wish to promulgate, might be set forth as follows:

1. Do not feel absolutely certain of anything.
2. Do not think it worthwhile to proceed by concealing evidence, for the evidence is sure to come to light.
3. Never try to discourage thinking for you are sure to succeed.
4. When you meet with opposition, even if it should be from your husband or your children, endeavor to overcome it by argument and not by authority, for a victory dependent upon authority is unreal and illusory.
5. Have no respect for the authority of others, for there are always contrary authorities to be found.
6. Do not use power to suppress opinions you think pernicious, for if you do the opinions will suppress you.
7. Do not fear to be eccentric in opinion, for every opinion now accepted was once eccentric.
8. Find more pleasure in intelligent dissent than in passive agreement, for, if you value intelligence as you should, the former implies a deeper agreement than the latter.
9. Be scrupulously truthful, even if the truth is inconvenient, for it is more inconvenient when you try to conceal it.
10. Do not feel envious of the happiness of those who live in a fool's paradise, for only a fool will think that it is happiness.

10. An Algorithm for Solving Problems

“He (Richard Feynman) was always searching for patterns, for connections, for a new way of looking at something, but I suspect his motivation was not so much to understand the world as it was to find new ideas to explain. The act of discovery was not complete for him until he had taught it to someone else.”— Daniel Hillis

The Feynman Algorithm, which is a simplification of Richard Feynman’s technique to learn anything, is a good all purpose algorithm for solving problems. Cal Newport explains:

1. *Simplify the problem down to an “essential puzzle.” Here’s how Danny Hillis explained Feynman’s use of simplicity: “He always started by asking very basic questions like, ‘What is the simplest example?’ or ‘How can you tell if the answer is right?’ He asked questions until he reduced the problem to some essential puzzle that he thought he would be able to solve. Then he would set to work.”*
2. *Continually master new techniques and then apply them to your library of unsolved puzzles to see if they help. As mathematician Gian Carlo-Rota explained when describing Feynman’s use of this strategy: “Every once in a while there will be a hit, and people will say: ‘How did he do it? He must be a genius!’”*

11. Why Can't Someone Be Taught Until They're Ready To Learn?

Clay Christensen is best known as the author of The Innovator's Dilemma. He's also the author of a new book, How Will You Measure Your Life?, which has some wonderful insights (see excerpts [here](#) and [here](#)).

The founder of 37Signals, Jason Fried, recently spent some time with Christensen and gained a key insight into why we can't be taught until we're ready to learn. Simply put, if you stop asking questions, you'll stop learning.

Spending time with Clay leads to lots of interesting insights, but for me, there was one that stood out among all the others.

You've probably heard it said that someone can't be taught until they're ready to learn. I've heard it said that way too. It makes sense, and my experience tells me it's mostly true.

Why though? Why can't someone be taught until they're ready to learn?

Clay explained it in a way that I've never heard before and I'll never forget again.

Paraphrased slightly, he said: "Questions are places in your mind where answers fit. If you haven't asked the question, the answer has nowhere to go. It hits your mind and bounces right off. You have to ask the question – you have to want to know – in order to open up the space for the answer to fit."

12. The Feynman Learning Technique

The Feynman Technique is the best way to supercharge your learning. And it works no matter the subject. Devised by Nobel Prize-winning physicist Richard Feynman, it leverages the power of teaching for better learning.

Learning doesn't happen from skimming through a book or remembering enough to pass a test.

Information is learned when you can explain it and use it in a wide variety of situations.

The Feynman Technique gets more mileage from the ideas you encounter instead of rendering anything new into isolated, useless factoids.

When you really learn something, you give yourself a tool to use for the rest of your life.

The more you know, the fewer surprises you will encounter because most new things will connect to something you already understand.

Ultimately, the point of learning is to understand the world. But most of us don't bother to deliberately learn anything.

We memorize what we need to as we move through school, then forget most of it. As we continue through life, we don't extrapolate from our experiences to broaden the applicability of our knowledge. Consequently, life kicks us in the ass time and again.

To avoid the pain of being bewildered by the unexpected, the Feynman Technique helps you turn information into knowledge that you can access as easily as reaching for a chair.

*

The Feynman Technique

"Any intelligent fool can make things bigger, more complex, and more violent. It takes a touch of genius—and a lot of courage—to move in the opposite direction."

E.F. Schumacher

There are four steps to the Feynman Learning Technique, based on the method Richard Feynman originally used. We have adapted it slightly after reflecting on our own experiences using this process to learn. The steps are as follows:

1. Pretend to teach a concept you want to learn about to a student in the sixth grade.
2. Identify gaps in your explanation. Go back to the source material to better understand it.
3. Organize and simplify.
4. Transmit (optional).

Step 1: Pretend to teach it to a child

Take out a blank sheet of paper. At the top, write the subject you want to master. Now write out everything you know about the subject as if you were teaching it to a child or a rubber duck sitting on your desk.

It's important to remember that you are not teaching to your smart adult friend, but rather a child who has just enough vocabulary and attention span to understand basic concepts and relationships. It has to be simple and clear. There is nowhere to hide in obfuscation.

Or, for a different angle on the Feynman Technique, you could place a rubber duck on your desk and try explaining the concept to it. Software engineers sometimes tackle debugging by explaining their code, line by line, to a rubber duck. It sounds silly, but it's a forcing function to make you walk through your thinking as simply as possible.

It turns out that one of the ways we mask our lack of understanding is by using complicated vocabulary and jargon. The truth is, if you can't clearly and simply define the words and terms you are using, you don't really know what you're talking about.

If you look at a painting and describe it as "abstract" because that's what you heard in art class, you demonstrate no understanding. You're just mimicking what you've heard. You haven't learned anything.

When you write out an idea from start to finish in simple language that a child can understand, you force yourself to understand the concept at a deeper level and simplify relationships and connections between ideas. You can better explain the why behind your description of the what.

Writing helps you think because it gives you nowhere to hide.

Looking at the painting again, you will be able to say that the painting doesn't display buildings like the ones we look at every day. Instead, it uses certain shapes and colors to depict a city landscape. You will be able to point out what these are. You will be able to engage in speculation about why the artist chose those shapes and those colors. You will be able to explain why artists sometimes do this, and you will be able to communicate what you think of the piece considering all of this.

Chances are, after capturing a full explanation of the painting in the simplest possible terms that would be easily understood by a sixth-grader, you will have learned a lot about that painting and abstract art in general.

Some of capturing what you would teach will be easy. These are the places where you have a clear understanding of the subject. But you will find many places where things are much foggier.

Step 2: Identify gaps in your explanation

Areas, where you struggle in Step 1, are the points where you have some gaps in your understanding.

Identifying gaps in your knowledge—where you forget something important, aren't able to explain it, or simply have trouble thinking of how variables interact—is a critical part of the learning process.

Filling those gaps is when you really make the learning stick.

Now that you know where you have gaps in your understanding go back to the source material. Augment it with other sources. Look up definitions. Keep going until you can explain everything you need to in basic terms.

Only when you can explain your understanding without jargon and in simple terms can you demonstrate understanding. Think about it this way. If you require complicated terminology to explain what you know, you have no flexibility. When someone asks you a question, you can only repeat what you've already said.

Simple terms can be rearranged and easily combined with other words to communicate your point. When you can say something in multiple ways using different words, you understand it really well.

Being able to explain something in a simple, accessible way shows you've done the work required to learn. Skipping it leads to the illusion of knowledge—an illusion that can be quickly shattered when challenged.

Identifying the boundaries of your understanding is also a way of defining your circle of competence. When you know what you know (and are honest about what you don't know), you limit the mistakes you're liable to make and increase your chance of success when applying knowledge.

Step 3. Organize and simplify

Now you have a set of hand-crafted notes containing a simple explanation. Organize them into a narrative that you can tell from beginning to end. Read it out loud. If the explanation sounds confusing at any point, go back to Step 2. Keep iterating until you have a story that you can tell to anyone who will listen.

If you follow this approach over and over, you will end up with a binder full of pages on different subjects. If you take some time twice a year to go through this binder, you will find just how much you retain.

Step 4: Transmit (optional)

This part is optional, but it's the logical result of everything you've just done.

If you really want to be sure of your understanding, run it past someone (ideally someone who knows little of the subject).

The ultimate test of your knowledge is your capacity to convey it to another. You can read out directly what you've written. You can present the material like a lecture. You can ask your friends for a few minutes of their time while you're buying them dinner. You can volunteer as a guest speaker in your child's classroom or your parents' retirement residence. All that really matters is that you attempt to transmit the material to at least one person who isn't that familiar with it.

The questions you get and the feedback you receive are invaluable for further developing your understanding.

Hearing what your audience is curious about will likely pique your own curiosity and set you on a path for further learning. After all, it's only when you begin to learn a few things really well do you appreciate how much there is to know.

The Feynman Technique is not only a wonderful recipe for learning but also a window into a different way of thinking that allows you to tear ideas apart and reconstruct them from the ground up. It also allows you to supercharge your learning from others.

Too often, we want to seem smart rather than learn. We nod along even when we don't understand what someone is talking about. This is a missed opportunity for learning. If you're having a conversation with someone and they start using jargon that you don't understand, ask them to explain it to you like you're twelve. Not only will you supercharge your own learning, but you'll also supercharge theirs.

Feynman's approach intuitively believes that intelligence is a process of growth, which dovetails nicely with the work of Carol Dweck, who describes the difference between a fixed and growth mindset.

"If you can't reduce a difficult engineering problem to just one 8-1/2 x 11-inch sheet of paper, you will probably never understand it."

—Ralph Peck

What does it mean to "know?"

Richard Feynman believed that *"the world is much more interesting than any one discipline."* He understood the difference between knowing something and knowing the name of something, as well as how, when you truly know something, you can use that knowledge broadly.

When you only know what something is called, you have no real sense of what it is.

You can't take it apart and play with it or use it to make new connections and generate new insights. When you know something, the labels are unimportant because it's not necessary to keep it in the box it came in.

"The person who says he knows what he thinks but cannot express it usually does not know what he thinks."

—Mortimer Adler

Feynman's explanations—on why questions, why trains stay on the tracks as they go around a curve, how we look for new laws of science, or how rubber bands work—are simple and powerful. He doesn't hide behind abstraction or jargon.

Here he articulates the difference between knowing the name of something and understanding it.

"See that bird? It's a brown-throated thrush, but in Germany it's called a halzenfugel, and in Chinese they call it a chung ling, and even if you know all those names for it, you still know nothing about the bird. You only know something about people: what they call the bird. Now that thrush sings, and teaches its young to fly, and flies so many miles away during the summer across the country, and nobody knows how it finds its way."

13. A Simple Tool to Help You Learn Better

Learning something new shouldn't be easy. If it feels effortless, you're probably not actually learning anything. In order to get better, you have to reach. It needs to be a little bit difficult.

From The Little Book of Talent: 52 Tips for Improving Your Skills:

Research shows that people who follow strategy B [read ten pages at once, then close the book and write a one page summary] remember 50 percent more material over the long term than people who follow strategy A [read ten pages four times in a row and try to memorize them]. This is because of one of deep practice's most fundamental rules: Learning is reaching. Passively reading a book—a relatively effortless process, letting the words wash over you like a warm bath—doesn't put you in the sweet spot. Less reaching equals less learning.

On the other hand, closing the book and writing a summary forces you to figure out the key points (one set of reaches), process and organize those ideas so they make sense (more reaches), and write them on the page (still more reaches, along with repetition). The equation is always the same: More reaching equals more learning.

You don't have to write a summary in paragraph format either. You can simply write bullet points. And while you can use the author's terminology, it's much better to use your own. This is part of the idea behind our blank sheet approach to instantly improve your ability to retain, connect, and use the information you're reading.

14. Stretching yourself to learn new things

Carol Dweck, Daniel Coyle, and Noel Tichy all point out that you need to stretch to learn new things.

First, this from Carol Dweck ...

My colleagues and I have conducted interventions with adolescents in which they learn that their brains and intellect are malleable. They discover that when they stretch themselves to learn new things, their neurons form new connections and they can, over time, enhance their intellectual skills. Compared to a control group that learned only study skills, these students showed marked improvements in motivation, and their declining grades were sharply reversed. Researchers Catherine Good and Joshua Aronson have found similar effects. In studies led by David Yeager, high school students who were taught a malleable view of their intellectual and social skills showed positive changes in their grades, stress level, conduct (including aggression), and health that lasted over the course of the school year.

Second, this passage from The Little Book of Talent: 52 Tips for Improving Your Skills:

There is a place, right on the edge of your ability, where you learn best and fastest. It's called the sweet spot. ... the underlying pattern is the same: Seek out ways to stretch yourself. Play on the edges of your competence. As Albert Einstein said, "One must develop an instinct for what one can just barely achieve through one's greatest efforts." The key word is "barely."

Finally, this passage from Deliberate Practice:

Noel Tichy, professor at the University of Michigan business school and the former chief of General Electric's famous management development center at Crotonville, puts the concept of practice into three zones: the comfort zone, the learning zone, and the panic zone.

Most of the time we're practicing we're really doing activities in our comfort zone. This doesn't help us improve because we can already do these activities easily. On the other hand, operating in the panic zone leaves us paralyzed as the activities are too difficult and we don't know where to start. The only way to make progress is to operate in the learning zone, which are those activities that are just out of reach.

Update: This passage from The Art of Learning fits as well:

Usually, growth comes at the expense of previous comfort or safety. The hermit crab is a colorful example of a creature that lives by this aspect of the growth process (albeit without our psychological baggage). As the crab gets bigger, it needs to find a more spacious shell. So the slow, lumbering creature goes on a quest for a new home. If an appropriate new shell is not found quickly, a terribly delicate moment of truth arises. A soft creature that is used to the protection of built-in armor must now go out into the world, exposed to predators in all its mushy vulnerability. That learning phase in between shells is where our growth can come from.

15. The Art of Learning

Josh Waitzkin has mastered the game of Chess — winning his first National Championship at the age of nine — and the physical challenge of martial arts, becoming a World Champion of Tai Chi Chuan. One thing Josh is good at is learning to master new skills. I want to highlight two passages from his book, The Art of Learning: An Inner Journey to Optimal Performance, for readers.

The first one speaks to why Josh could come into a new sport, Tai Chi Chuan, and advance faster than others who had been practicing for years longer than he had. He was willing to lose to win.

It seemed that many other students were frozen in place, repeating their errors over and over, unable to improve because of a fear of releasing old habits. When Chen (the master teaching the students) made suggestions, they would explain their thinking in an attempt to justify themselves. They were locked in a need to be correct.

Waitzkin's philosophy was that if you could maximize the learning from your mistakes and avoid repeating them you would skyrocket to the top of any field. While it's impossible to avoid repeating every mistake, Waitzkin tried to minimize repetition of them by not letting his ego get in the way.

The second passage I want to share with you is on learning. The theme is depth over breadth.

The learning principle is to plunge into the detailed mystery of the micro in order to understand what makes the macro tick. Our obstacle is that we live in an attention-deficit culture. We are bombarded with more and more information on television, radio, cell phones, video games, the Internet. The constant supply of stimulus has the potential to turn us into addicts, always hungering for something new and prefabricated to keep us entertained. When nothing exciting is going on, we might get bored, distracted, separated from the moment. So we look for new entertainment, surf channels, flip through magazines. If caught in these rhythms, we are like tiny current-bound surface fish, floating along a two-dimensional world without any sense for the gorgeous abyss below. When these societally induced tendencies translate into the learning process, they have devastating effect.

... Many "Kung Fu" schools fuel this problem by teaching numerous flowery forms, choreographed sets of movement, and students are rated by how many forms they know. Everyone races to learn more and more, but nothing is done deeply. Things look pretty but they are superficial, without a sound body mechanic or principled foundation. Nothing is learned at a high level and what results are form collectors with fancy kicks and twirls that have absolutely no martial value.

16. Josh Waitzkin on Mastering the Fundamentals

Some excerpts from Josh Waitzkin's The Art of Learning: An Inner Journey to Optimal Performance.

The best way to launch into the learning process is by breaking down what you are learning into its fundamental building blocks. Mastering these builds your foundation.

Learning Chess

Bruce (his teacher) began our study with a barren chessboard. We took on positions of reduced complexity and clear principles. Our first focus was king and pawn against king—just three pieces on the table....Layer by layer we built up my knowledge and my understanding of how to transform axioms into fuel for creative insight....This method of study gave me a feeling for the beautiful subtleties of each chess piece, because in relatively clear-cut positions I could focus on what was essential. I was also gradually internalizing a marvelous methodology of learning—the play between knowledge, intuition, and creativity. From both educational and technical perspectives, I learned from the foundation up.

“Most of my rivals, on the other hand, began by studying opening variations ... Once you start with openings, there is no way out ... It is a little like developing the habit of stealing the test from your teacher’s desk instead of learning how to do the math. You may pass the test, but you learn absolutely nothing—and most critically, you don’t gain an appreciation for the value or beauty of learning itself.”

Tai Chi Chuan

From very early on, I felt that the moving meditation of Tai Chi Chuan has the primary martial purpose of allowing practitioners to refine certain fundamental principles. Many of them can be explored by standing up, taking a stance, and incrementally refining the simplest of movements—for example pushing your hands six inches through the air ... I practiced the Tai Chi meditative form diligently, many hours a day. At times I repeated segments of the form over and over, honing certain techniques while refining my body mechanics and deepening my sense of relaxation. I focused on small movements, sometimes spending hours moving my hand out a few inches, then releasing it back, energizing outwards, connecting my feet to my fingertips with less and less obstruction ... the key was to recognize that the principles making one simple technique tick were the same fundamentals that fueled the whole expansive system of Tai Chi Chuan.

17. Value Process Before Results

More insight from The Art of Learning: An Inner Journey to Optimal Performance:

The issue is fundamental to the pursuit of excellence in all fields. If a young basketball player is taught that winning is the only thing that winners do, then he will crumble when he misses his first big shot. If a gymnast or ballet dancer is taught that her self-worth is entirely wrapped up in a perfectly skinny body that is always ready for performance, then how can she handle injuries or life after an inevitably short career? If a businessperson cultivates a perfectionist self-image, then how can she learn from her mistakes?

And this quote based on research by Dr. Carol Dweck.

Children who are “entity theorists” ... are prone to use language like ‘I am smart at this.’ And to attribute their success or failure to an ingrained and unalterable level of ability. They see their overall intelligence or skill level at a certain discipline to be a fixed entity, a thing that cannot evolve. Incremental theorists, who have picked up a different modality of learning, are more prone to describe their results with sentences like ‘I got it because I worked very hard at it’ or ‘I should have tried harder.’ A child with a learning theory of intelligence tends to sense that with hard work, difficult material can be grasped- step-by-step, incrementally, the novice can become the master.

18. The Seductive Path of Good Enough

The ability to learn new skills is the entry ticket for being a knowledge worker. If you can't learn and adapt, you fall flat on your face. But not all of us learn at the same pace, and not all of us reach the same level of mastery. Some of us get better with experience, and some of us seem to keep making the same mistakes over and over. Why?

When we learn any new skill, we usually learn just enough to become competent, and then our brains switch to autopilot. They're lazy that way.

The brain tries to conserve as much energy as it can. And while practice is easy, deliberate practice is not.

So much of success is just showing up day after day and grinding away at the hard parts in a deep and focused way. However simple that sounds, it's not easy. And that's why most of us struggle to get better.

Perhaps an example will help illustrate what I'm talking about. Consider driving. Most of us can drive. It's a skill we learned. At first, we were terrible and nervous. Through deliberate practice and coaching, we got better and better. We reached some level of competence and verified this through a test. I don't know about you, but despite having spent thousands of hours behind the wheel since then, I've probably gotten only marginally better at driving.

Why?

There are many reasons. One is that I lack feedback. There is no expert coaching me and telling me where to improve. Another reason is that I don't even know what I want to improve. What does it mean to become a better driver? Getting better sounds like a lot of work. And that's the rub.

We're hard-wired to avoid pain. This tendency includes reflecting on our decisions as well as practicing skills. Once we reach some base level of competence, we practice that part over and over and shy away from the parts that might make us better. In short, I've been driving the same way for thousands of hours, practicing skills I already had instead of trying new things.

“By nature, we humans shrink from anything that seems possibly painful or overtly difficult.”

— Robert Greene

However, a base level of competence doesn't get us ahead of anyone or set us apart. The base-level comprises the most easily acquired aspects of any particular skill and the bare minimum we need to do to claim that skill. And most of the time, we've learned the conventional way of doing things — it's a form of social proof where we just mimic what other people have done. Because we acquire the most easily accessible parts of any skill, we also over-estimate our competence. (I think this is why we all rate ourselves as above average at very basic things like driving.)

Stopping here is a hallmark of amateurs.

The only way to get better at a task is through deliberate practice. The idea is simple: instead of avoiding pain, you dive in. How?

First, use the mental model of Galilean Relativity to switch perspectives and see yourself through the eyes of others. This will allow you to recognize the areas that you need to improve. Recognizing these areas is necessary if you want to improve.

Second, set aside time for dedicated focus on the specific area you want to improve. A lot of people don't understand this, but when you're really focused on something, you can rapidly get better at it. At any given time, most of us are only half-focused on what we're doing. (How many browser tabs are open right now? What's on your grocery list?) You really need to immerse yourself in the task at hand.

You also need feedback. Sometimes the task itself can give you feedback, sometimes you'll want a coach, and sometimes you can have both. When I was learning to drive, the car was giving me instant feedback, but my learning was accelerated by having a coach tell me what was happening, why, and how I could handle it.

Third, push the limits of what you can do so you understand your boundaries. This also helps you stay calm if things don't go as planned. Driving in the snow is not easy, and it's often dangerous. I remember one day when my instructor took me to an empty parking lot covered in snow. He looked at me and said, "I want you to go as fast as you can and lose control of the car."

I was shocked.

"You're going to lose control of a car in the snow at some point. Might as well be here where no one is around."

And that day probably saved my life. I knew what it felt like to lose control of the car. And because I knew what to expect, I wasn't panicked when it happened. More important, through practicing over and over for hours, I knew the best strategies to regain control of the car.

Finally, rinse and repeat over and over again.

You don't want to do this level of work with every skill. But if you can identify the ones that give you leverage, doing this work is how you get better.

19. Charlie Munger: How to Teach Business School

Everyone has an opinion on what to teach at business school. Few are as informed or timeless as Charlie Munger, the billionaire business partner of Warren Buffett at Berkshire Hathaway. Here's what he had to say on the subject at the 2011 annual meeting for Berkshire Hathaway Shareholders:

Costco of course is a business that became the best in the world in its category. And it did it with an extreme meritocracy, and an extreme ethical duty—self-imposed to take all its cost advantages as fast as it could accumulate them and pass them on to the customers. And of course they've created ferocious customer loyalty. It's been a wonderful business to watch—and of course strange things happen when you do that and when you do that long enough. Costco has one store in Korea that will do over \$400 million in sales this year. These are figures that can't exist in retail, but of course they do. So that's an example of somebody having the right managerial system, the right personnel solution, the right ethics, the right diligence, etcetera, etcetera. And that is quite rare. If once or twice in your lifetime you're associated with such a business you're a very lucky person.

The more normal business is a business like, say, General Motors, which became the most successful business of its kind in the world and wiped out its common shareholders... what, last year? That is a very interesting story—and if I were teaching business school I would have Value-Line-type figures that took me through the entire history of General Motors and I would try to relate the changes in the graph and data to what happened in the business. To some extent, they faced a really difficult problem—heavily unionized business, combined with great success, and very tough competitors that came up from Asia and elsewhere in Europe. That is a real problem which of course... to prevent wealth from killing people—your success turning into a disadvantage—is a big problem in business.

And so there are all these wonderful lessons in those graphs. I don't know why people don't do it. The graphs don't even exist that I would use to teach. I can't imagine anybody being dumb enough not to have the kind of graphs I yearn for. [Laughter] But so far as I know there's no business school in the country that's yearning for these graphs. Partly the reason they don't want it is if you taught a history of business this way, you'd be trampling on the territories of all the professors and sub-disciplines—you'd be stealing some of their best cases. And in bureaucracies, even academic bureaucracies, people protect their own turf. And of course a lot of that happened at General Motors. [Applause]

I really think the world ... that's the way it should be taught. Harvard Business School once taught it much that way—and they stopped. And I'd like to make a case study as to why they stopped. [Laughter] I think I can successfully guess. It's that the course of history of business trampled on the territory of barons of other disciplines like the baron of marketing, the baron of finance, the baron of whatever.

IBM is an interesting case. There's just one after another that are just utterly fascinating. I don't think they're properly taught at all because nobody wants to do the full sweep.

20. Kathryn Schulz on why Knowledge Collapses as often as it Accretes

Kathryn Schulz comments on the fantasy that knowledge is static in [This Will Make You Smarter: New Scientific Concepts to Improve Your Thinking](#).

Because so many scientific theories from bygone eras have turned out to be wrong, we must assume that most of today's theories will eventually prove incorrect as well. And what goes for science goes in general. Politics, economics, technology, law, religion, medicine, child-rearing, education: no matter the domain of life, one generation's verities so often become the next generation's falsehoods that we might as well have a Pessimistic Meta-Induction from the History of Everything.

Good scientists understand this. They recognize that they are part of a long process of approximation. They know that they are constructing models rather than revealing reality... The rest of us, by contrast, often engage in a kind of tacit chronological exceptionalism. Unlike all those suckers who fell for the flat earth or the geocentric universe or cold fusion or the cosmological constant, we ourselves have the great good luck to be alive during the very apex of accurate human thought. The literary critic Harry Levin put this nicely: "The habit of equating one's age with the apogee of civilization, one's town with the hub of the universe, one's horizons with the limits of human awareness, is paradoxically widespread." At best, we nurture the fantasy that knowledge is always cumulative, and therefore concede that future eras will know more than we do. But we ignore or resist the fact that knowledge collapses as often as it accretes, that our own most cherished beliefs might appear patently false to posterity.

That fact is the essence of the meta-induction — and yet, despite its name, this idea is not pessimistic. Or rather, it is only pessimistic if you hate being wrong. If, by contrast, you think that uncovering your mistakes is one of the best ways to revise and improve your understanding of the world, then this is actually a highly optimistic insight.

21. Robert Greene explains the Process to Attain Mastery

The relationship between people and their craft is such that you can tell by the path they have followed whether they are a master or an amateur.

Robert Greene, most famous for his exposure of power, The 48 Laws of Power, is out with a new book: Mastery.

There exists a form of power and intelligence that represents the high point of human potential. It is the source of the greatest achievements and discoveries in history. It is an intelligence that is not taught in our schools nor analyzed by professors, but almost all of us, at some point, have had glimpses of it in our own experience.

At its core, Mastery is a simple process accessible to all of us. But before you start down the path, you need to bring two traits to the table: the relentless ability to focus deeply on a subject and a strong desire to learn.

The process can be illustrated in the following way:

Let us say we are learning the piano, or entering a new job where we must acquire certain skills. In the beginning, we are outsiders. Our initial impressions of the piano or the work environment are based on prejudgments, and often contain an element of fear. When we first study the piano, the keyboard looks rather intimidating—we don't understand the relationships between the keys, the chords, the pedals, and everything else that goes into creating music. In a new job situation, we are ignorant of the power relationships between people, the psychology of our boss, the rules and procedures that are considered critical for success. We are confused—the knowledge we need in both cases is over our heads. Although we might enter these situations with excitement about what we can learn or do with our new skills, we quickly realize how much hard work there is ahead of us. The great danger is that we give in to feelings of boredom, impatience, fear, and confusion. We stop observing and learning. The process comes to a halt.

If, on the other hand, we manage these emotions and allow time to take its course, something remarkable begins to take shape. As we continue to observe and follow the lead of others, we gain clarity, learning the rules and seeing how things work and fit together. If we keep practicing, we gain fluency; basic skills are mastered, allowing us to take on newer and more exciting challenges. We begin to see connections that were invisible to us before. We slowly gain confidence in our ability to solve problems or overcome weaknesses through sheer persistence.

At a certain point, we move from student to practitioner. We try out our own ideas, gaining valuable feedback in the process. We use our expanding knowledge in ways that are increasingly creative. Instead of just learning how others do things, we bring our own style and individuality into play.

As years go by and we remain faithful to this process, yet another leap takes place—to mastery. The keyboard is no longer something outside of us; it is internalized and becomes part of our nervous system, our fingertips. In our career, we now have a feel for the group dynamic, the current state of business. We can apply this feel to social situations, seeing deeper into other people and anticipating their reactions. We can make decisions that are rapid and highly creative. Ideas come to us. We have learned the rules so well that we can now be the ones to break or rewrite them.

Greene argues that we can all be Masters but we must follow three phases:

apprenticeship, creative-active, and mastery. The problem is over-coming our hunger for magical shortcuts. We want the easy route.

To the extent that we believe we can skip steps, avoid the process, magically gain power through political connections or easy formulas, or depend on our natural talents, we move against this grain and reverse our natural powers. We become slaves to time—as it passes, we grow weaker, less capable, trapped in some dead-end career. We become captive to the opinions and fears of others. Rather than the mind connecting us to reality,

we become disconnected and locked in a narrow chamber of thought. The human that depended on focused attention for its survival now becomes the distracted scanning animal, unable to think in depth, yet unable to depend on instincts.

It is the height of stupidity to believe that in the course of your short life, your few decades of consciousness, you can somehow rewire the configurations of your brain through technology and wishful thinking, over-coming the effect of six million years of development. To go against the grain might bring temporary distraction, but time will mercilessly expose your weakness and impatience.

The difference between Masters and amateurs is simpler than you may think. One of the keys is tenacity.

Whenever we learn a skill, we frequently reach a point of frustration—what we are learning seems beyond our capabilities. Giving in to these feelings, we unconsciously quit on ourselves before we actually give up.

It's in our nature to shy away from anything that seems difficult or painful. In doing so, we take the path of the amateur.

“Do not talk about giftedness, inborn talents! One can name great men of all kinds who were very little gifted. They acquired greatness, became ‘geniuses’ (as we put it), through qualities the lack of which no one who knew what they were would boast of: they all possessed that seriousness of the efficient workman which first learns to construct the parts properly before it ventures to fashion a great whole; they allowed themselves time for it, because they took more pleasure in making the little, secondary things well than in the effect of a dazzling whole.”

— Friedrich Nietzsche

More than just some tails of historical figures, Greene offers some penetrating insights into human behavior.

We feel, rightly so, that no one should be admired or worshipped merely for the position they occupy, particularly if it comes from connections or a privileged background. But this attitude carries over to people who have reached their position mostly through their own accomplishments. We live in a culture that likes to criticize and debunk any form of authority, to point out the weaknesses of those in power. If we feel any aura, it is in the presence of celebrities and their seductive personalities. Some of this skeptical spirit toward authority is healthy, particularly in relation to politics, but when it comes to learning and the Apprenticeship Phase, it presents a problem.

To learn requires a sense of humility

We must admit that there are people out there who know our field much more deeply than we do. Their superiority is not a function of natural talent or privilege, but rather of time and experience. Their authority in the field is not based on politics or trickery. It is very real. But if we are not comfortable with this fact, if we feel in general mistrustful of any kind of authority, we will succumb to the belief that we can just as easily learn something on our own, that being self-taught is more authentic. We might justify this attitude as a sign of our independence, but in fact it stems from basic insecurity. We feel, perhaps unconsciously, that learning from Masters and submitting to their authority is somehow an indictment of our own natural ability. Even if we have teachers in our lives, we tend not to pay full attention to their advice, often preferring to do things our own way. In fact, we come to believe that being critical of Masters or teachers is somehow a sign of our intelligence, and that being a submissive pupil is a sign of weakness.

Why do we need a mentor?

Life is short; you have only so much time and so much energy to expend. Your most creative years are generally in your late twenties and on into your forties. You can learn what you need through books, your own practice, and occasional advice from others, but the process is hit-and-miss. The information in books is not tailored to your circumstances and individuality; it tends to be somewhat abstract. When you are young and have less

experience of the world, this abstract knowledge is hard to put into practice. You can learn from your experiences, but it can often take years to fully understand the meaning of what has happened. It is always possible to practice on your own, but you will not receive enough focused feedback. You can often gain a self-directed apprenticeship in many fields, but this could take ten years, maybe more.

Mentors do not give you a shortcut, but they streamline the process. They invariably had their own great mentors, giving them a richer and deeper knowledge of their field. Their ensuing years of experience taught them invaluable lessons and strategies for learning. Their knowledge and experience become yours; they can direct you away from unnecessary side paths or errors. They observe you at work and provide real-time feedback, making your practice more time efficient. Their advice is tailored to your circumstances and your needs. Working closely with them, you absorb the essence of their creative spirit, which you can now adapt in your own way. What took you ten years on your own could have been done in five with proper direction.

There is more to this than just time saved. When we learn something in a concentrated manner it has added value. We experience fewer distractions. What we learn is internalized more deeply because of the intensity of our focus and practice. Our own ideas and development flourish more naturally in this shortened time frame. Having an efficient apprenticeship, we can make the most of our youthful energy and our creative potential.

The career of Warren Buffett very much fit Greene's arc: Buffett apprenticed with Benjamin Graham in New York, honed his skills and evolved his process running the Buffett Partnership and the early years of Berkshire Hathaway, and is now widely considered a master investor.

I found Greene's book engaging despite the fact that I'm not normally a fan of anecdotal accounts. No doubt a lot of people have followed the same path yet never achieved the success necessary to be recognized as Masters. An assured way to success, this book is not.

Contrary to Greene, I'd argue that we all can't be Masters. Yet that doesn't mean we can't benefit from Greene's book.

22. The Secret Ingredient for Success: The Brutal Discipline Necessary for Self-Assessment

Camille Sweeney and Josh Gosfield, authors of The Art of Doing: How Superachievers Do What They Do and How They Do It So Well, came out with an op-ed in the New York Times.

The interesting argument, one that is echoed by Charles Darwin, is that the to success is a brutal self-assessment.

“Discipline is the attitude that helps us discern right from wrong ... Discipline is what makes us responsible toward ourselves [and] toward the society in which we live.”

— Massimo Vignelli

What happens to organizations and people when they find obstacles in their paths?

Professor Argyris called the most common response single loop learning — an insular mental process in which we consider possible external or technical reasons for obstacles. LESS common but vastly more effective is the cognitive approach that Professor Argyris called double-loop learning. In this mode we — like Mr. Chang — question every aspect of our approach, including our methodology, biases and deeply held assumptions. This more psychologically nuanced self-examination requires that we honestly challenge our beliefs and summon the courage to act on that information, which may lead to fresh ways of thinking about our lives and our goals.

In interviews we did with high achievers... we expected to hear that talent, persistence, dedication and luck played crucial roles in their success. Surprisingly, however, self-awareness played an equally strong role.

The successful people we spoke with — in business, entertainment, sports and the arts — all had similar responses when faced with obstacles: they subjected themselves to fairly merciless self-examination that prompted reinvention of their goals and the methods by which they endeavoured to achieve them.

In part, an accurate self-assessment allows for the feedback necessary to grow. It's the evidence you need to move forward. It doesn't matter if it comes from nobodies or somebodies, a coach or anyone else, which is precisely the point of being open to what others have to say if you are really interested in improving your own skills.

The discipline of self-assessment is only the start. It produces knowledge that allows us to understand the edge of our competency, which is the key to learning. What you do with that knowledge matters and there is a difference between the good and the great.

Average performers believe their errors are caused by things they don't control — a fixed mindset if there ever was one. Top performers, however, as Geoff Colvin writes in his book, Talent is Overrated, “believe they are responsible for their errors.”

Note that this is not just a difference of personality or attitude. Recall that the best performers have set highly specific, technique-based goals and strategies for themselves; they have thought through exactly how they intend to achieve what they want. So when something doesn't work, they can relate the failure to specific elements of their performance that may have misfired. (more)

It's precisely the combination of a brutal self-assessment and a growth mindset that tilts that increases the odds we become better. And these skills come down to discipline.

As Anna Deavere Smith wrote in Letters to a Young Artist: Straight-up Advice on Making a Life in the Arts for Actors, Performers, Writers, and Artists of Every Kind, *Discipline — both mental and physical — is crucial.*

23. Gossip

Nobody is untouched by gossip. We dish it. We listen to it. Or, least desirably, we are the subject of it.

One definition of gossip is “bits of news about the personal affairs of others.” We gossip about many things from appearances to habits. The best gossip, however, is usually found in the intimate secrets of others.

In Joseph Epstein’s book, *Gossip: The Untrivial Pursuit*, he explores the ever expanding roll gossip plays in our lives—from trivial pursuit to political weapon—and how the internet has, once again, changed everything.

The most enticing gossip is that which is highly feasible, often uncheckable, and deeply damning of the person who is its subject.

Gossip requires “two or more people telling things about a third that the latter would prefer not to be know.” In case you’re wondering, it matters not whether the gossip is true – if it is, so much the better.

The Uses of Gossip

Gossip does have its uses. Sociologists, for instances, have found much meaning in gossip.

In certain settings—the workplace, in large corporate offices, in government, in universities—gossip, as a source of funneling rumors recounting what is happening in the inner sanctum of an institution, may be the only way that workers have of finding out beforehand decisions that might have momentous effects on their future. Gossip can also be a relatively efficient way in which to acquire knowledge of the character of colleagues.

Gossip gives us a sense of what’s happening and allows us to feel integrated into the organization. According to Sloan Wilson, a professor of biology and anthropology at Binghamton University, “gossip appears to be a very sophisticated, multifunction interaction which is important in policing behaviour in a group and defining group membership.”

It also helps educate us to our cultural and social world. Sarah Wert, a psychologist at the University of Colorado adds: “We all know people who are not calibrated to the social world at all, who if they participated in gossip sessions would learn a whole lot of stuff they need to know and can’t learn anywhere else, like how reliable people are, how trustworthy. Not participating in gossip at some level can be unhealthy, and abnormal.”

*Gossip can enforce community norms and discourage bad behavior. “Although this is rarely its motive, gossip can act as a potential barrier to bad behavior, and in this sense can be a useful deterrent to such behavior. Some people will be restrained from acting badly if only because they fear that their conduct will be talked about behind their backs. Everything here depends, of course, on the quality of the community’s norms. If these norms are far from admirable, gossip of this kind turns naturally ugly. Illustrations of the effects of this kind of gossip are available in Nathaniel Hawthorne’s *The Scarlet Letter* and, much later, in Sinclair Lewis’s novels *Babbitt* and *Main Street*, where conformity to a community’s norms is crucial to one’s adjustment to adult life, though often, as both Hawthorne and Lewis make clear, at the exorbitant price of the loss of one’s true spirit and authentic personality.*

Alternatively, gossip can work the other way, and work to loosen community norms.

Reading about the behavior of the famous in gossip columns, people begin to think that their behavior, though it goes beyond established boundaries, perhaps isn’t so terrible after all.

Gossip can also be used to calibrate and elevate your status within the social circle. In 1944, C.S. Lewis delivered a lecture called “*The Inner Ring*.” In it, he describes that we can tell gossip for social approval:

I don't believe that the economic motive and the erotic motive account for everything that goes on in what we moralists call the World. Even if you add Ambition I think the picture is still incomplete. The lust for the esoteric, the longing to be inside, take many forms which are not easily recognizable as Ambition. We hope, no doubt, for tangible profits from every Inner Ring we penetrate: power, money, liberty to break rules, avoidance of routine duties, evasion of discipline. But all these would not satisfy us if we did not get in addition the delicious sense of secret intimacy. It is no doubt a great convenience to know that we need fear no official reprimands from our official senior because he is old Percy, a fellow-member of our ring. But we don't value the intimacy only for the sake of convenience; quite equally we value the convenience as a proof of the intimacy.

Rules

But Epstein argues there are rules to gossip. For instance, "No matter how deep his delight in gossip, the originator of it must never seem as if he worked hard at acquiring the information he is passing on. ... Were he to do so, he would come across as the most miserable of creatures, a damned busybody."

The best gossip, for Epstein, is "That which confirms my own views of the essential fraudulence of certain people, especially people who present themselves as a touch — and usually more than a touch — more moral than the rest of us."

We All Have Secrets

While we might prefer to hear about gossip concerning those in power or celebrities, we all have secrets. The English writer William Donaldson wrote in his diary:

The version of ourselves we present to the world bears no resemblance to the truth. If we knew the truth about each other we could take no-one seriously. There isn't one of us who could afford to be caught. That's all life is. Trying not to be found out.

Literature

Gossip, of course, is everywhere in literature.

Elizabeth Gaskell, the Brontes, Edith Wharton, and Henry James, novelists who had a strong interest in gossip and made good use of it in their fiction, understood both gossip's attractions and its literary value.

Commenting on having made an appearance in a novel, with a different name, Isaiah Berlin wrote to a colleague "To appear in a novel of this kind is rather like appearing in other people's dreams: and one cannot exactly avoid doing so, nor is one responsible for the shape one takes, and yet the results inevitably offend one. I wish people left one alone.

The Internet is Changing Gossip

A character in *The Last Puritan*, a novel by George Santayana, who was accused of a crime, and later acquitted, says "Being acquitted is nothing in this world. Being accused is what makes all the difference."

"The Internet," writes Daniel Solove, a legal scholar interested in the questions, problems, and issues of privacy, "is transforming the nature and effect of gossip."

In his book The Future of Reputation: Gossip, Rumor, and Privacy on the Internet, Solove recounts the story of an insensitive remark that appeared online, supposedly spoken by the clothing designer Tommy Hilfiger: "If I had known that African Americans, Hispanics, and Asians would buy my clothes, I would not have made them so nice." Hilfiger is also supposed to have confirmed that he made this most impolitic remark on Oprah, causing Ms. Winfrey to throw him off her show and tell her audience not to buy his clothes. The effect of this caused Hilfiger's business to slump drastically. The problem is that Tommy Hilfiger never made the remark, nor had he ever appeared on Oprah. But the story was out there in cyberspace; you will find it is still out there today.

The internet has given us splendid freedom to express opinions and thoughts. This is part of its tremendous benefit. But there is another side to that freedom, "the freedom to libel, to invade privacy, to wreck lives—that has got so little, though greatly needed, attention."

Professor Solove remarks that the Internet is, historically, in its adolescence — and it is precisely as an adolescent that it now tends to act: wildly, thoughtlessly, destructively. Lars Nelson, of the New York Daily News, has called the Internet, in this aspect of its young career, “a vanity press for the demented,” and this is more than an amusing phrase.

“Gossip has its good qualities,” writes Epstein, “in supplying important information not available in any other form. ... But on the harmful side, the Internet has quickened, and much intensified, the harm that gossip can do to its victims.”

The combination of malice with the Internet’s speed and permanency creates a nuclear weapon.

In the end, Epstein concludes, “Once a secret vice, gossip threatens to become the chief way we obtain our information, and there doesn’t appear much we can do about it.”

24. Become A Learning Machine

When successful people from different fields offer the same advice, I listen. Often they have different vocabulary around an idea, but when you break it down you realize they're talking about the same thing.

Below is an example of Charlie Munger, Carol Dweck, and Susan Cain, offering the same core advice: Become a Learning Machine.

If you want to go to bed smarter than you woke up, you need to learn something new each day. It doesn't matter how smart you are today; what matters it that you learn something new and useful. If you can simply repeat that day after day, you will find that you outperform others.

It can be hard to grasp this concept because the differences at first are small. Only as the days turn into weeks, the weeks into months, the months into years, and the years into decades will you look back and wonder how it happened.

Charlie Munger:

I constantly see people rise in life who are not the smartest, sometimes not even the most diligent, but they are learning machines. They go to bed every night a little wiser than they were when they got up and boy does that help, particularly when you have a long run ahead of you.

Carol Dweck says:

You have to apply yourself each day to becoming a little better. By applying yourself to the task of becoming a little better each and every day over a period of time, you will become a lot better.

And this tidbit from Susan Cain, also fits:

...identify the tasks or knowledge that are just out of your reach, strive to upgrade your performance, monitor your progress, and revise accordingly.

25. The Science of High Performance

Research shows that knowing what you want to accomplish is more important than performance ... at least at the start. But once you know where you're going, you can accelerate progress by religiously implementing these steps.

1. Routines

The first tip comes from Tony Schwartz author of The Power of Full Engagement and Be Excellent at Anything. In his contribution to Maximize Your Potential, he recommends harnessing the power of a ritual.

A ritual is a highly precise behavior you do at a specific time so that it becomes automatic over time and no longer requires much conscious intention or energy.

Willpower and discipline are over-rated. Systems matter more.

In his book, Willpower: Rediscovering the Greatest Human Strength, Roy Baumeister contends that the most successful people don't make better decisions because of their willpower. Rather, they develop routines and scripts.

These routines become automatic and reduce the number of decisions we need to make (as well as reducing stress). Our brain doesn't have unlimited resources so the more we can offload to routines and scripts the more we can put our limited energy to other things. Developing these routines are key. In Michael Lewis' profile of President Obama, he writes:

You also need to remove from your life the day-to-day problems that absorb most people for meaningful parts of their day. "You'll see I wear only gray or blue suits," (Obama) said. "I'm trying to pare down decisions. I don't want to make decisions about what I'm eating or wearing. Because I have too many other decisions to make." He mentioned research that shows the simple act of making decisions degrades one's ability to make further decisions. It's why shopping is so exhausting. "You need to focus your decision-making energy. You need to routinize yourself. You can't be going through the day distracted by trivia."

If we spend energy making too many little decisions, we'll have less to make the more important decisions. Some companies are cluing into this.

"I think that the leadership at Google has an intuitive understanding of human nature and the way attention is a limited resource," says David Rock author of Your Brain at Work.

Google organizes their environment to make allow their employees to make fewer decisions.

The formula at Club Med is to include pretty much everything in the price, activities, food, even drinks, giving you fewer decisions to make. Now I know the research on decision making, and how making any conscious decision uses a measurable amount of glucose, but I wasn't prepared for how relaxing it was not having to think anywhere near as much, even about simple things. It turned out to be a remarkably restful holiday.

When you work at google, you get to save your limited mental resources for the most important decisions. As Google's CEO Eric Schmidt said, "Let's face it: programmers want to program, they don't want to do their laundry. So we make it easy for them to do both."

...Other companies could do well to do the same, noticing what their employees end up wasting their attention on, and doing something about it. It's sure making me rethink my own company's benefits policies.

... as well as minimizing distractions and respecting attention, Google does other things to help its people be more productive, in particular being more productive at complex problem solving.

2. Focus

Your routines should be geared towards helping you focus.

In Your Brain at Work, David Rock writes:

One of the most effective distraction-management techniques is simple: switch off all communication devices during any thinking work. Your brain prefers to focus on things

right in front of you. It takes less effort. If you are trying to focus on a subtle mental thread, allowing yourself to be distracted is like stopping pain to enjoy a mild pleasure: it's too hard to resist! Blocking out external distractions altogether, especially if you get a lot of them, seems to be one of the best strategies for improving mental performance

Combining routine and focus is the sweet spot. Here are two examples you can put into practice today.

First, Mark McGuinness argues in Manage Your Day-to-Day that you should put your most important work first. It's much easier to deal with less taxing things, like email, later.

The single most important change you can make in your working habits is to switch to creative work first, reactive work second. This means blocking off a large chunk of time every day for creative work on your own priorities, with the phone and e-mail off.

Another way to think of this is to pay yourself first: you are your own most valuable client. That's what Warren Buffett and Charlie Munger do.

Another useful *routine* is to deal with email in batches, say from 10-11 and 3-4 each day. The rest of the day, turn the email client off so you're not constantly interrupted with 'new mail.'

Consider the wise counsel of Herbert Simon:

What information consumes is rather obvious: it consumes the attention of its recipients. Hence a wealth of information creates a poverty of attention, and a need to allocate that attention efficiently among the overabundance of information sources that might consume it.

3. Practice

Experience doesn't always make you better.

In Talent Is Overrated, Geoff Colvin writes:

In field after field, when it comes to centrally important skills—stockbrokers recommending stocks, parole officers predicting recidivism, college admissions officials judging applicants—people with lots of experience were no better at their jobs than those with less experience.

Wait. What? That doesn't make sense.

We typically operate in the OK Plateau.

The bestselling author of Moonwalking with Einstein and USA Memory Champion in 2005, Joshua Foer explains:

In the 1960s, psychologists identified three stages that we pass through in the acquisition of new skills. We start in the "cognitive phase," during which we're intellectualizing the task, discovering new strategies to perform better, and making lots of mistakes. We're consciously focusing on what we're doing. Then we enter the "associative stage," when we're making fewer errors, and gradually getting better. Finally, we arrive at the "autonomous stage," when we turn on autopilot and move the skill to the back of our proverbial mental filing cabinet and stop paying conscious attention. ... The OK Plateau is that point when we reach the autonomous stage and consciously or unconsciously stay to ourselves, "I am OK at how good I have gotten at this task," and stop paying attention to our improvement. We all reach OK Plateaus in almost everything we do. We learn to drive when we're teenagers, and at first we improve rapidly, but eventually we are no longer a threat to old ladies crossing the street, and we stop getting appreciably better.

If we want to perform better beyond some basic competence researchers say we must engage in deliberate practice. These are designed, mindful efforts, to master even the smallest detail of success. To get better you have to get out of the autonomous stage.

One way to stay out of the autonomous stage is deliberate practice. Expert musicians, for example, focus on the hardest parts not the easy ones that would allow them to sink into autopilot. The way to get better is to push your limits.

Unfortunately, deliberate practice isn't something that most of us understand, let alone engage in on a daily basis. This helps explain why we can work at something for decades without really improving our performance.

Colvin continues:

Deliberate practice is characterized by several elements, each worth examining. It is activity designed specifically to improve performance, often with a teacher's help; it can be repeated a lot; feedback on results is continuously available; it's highly demanding mentally, whether the activity is purely intellectual, such as chess or business-related activities, or heavily physical, such as sports; and it isn't much fun.

Consider a coach.

In his fascinating [New Yorker article](#), Doctor Atul Gawande writes "In theory, people can do this themselves."

But most people do not know where to start or how to proceed. Expertise, as the formula goes, requires going from unconscious incompetence to conscious incompetence to conscious competence and finally to unconscious competence. The coach provides the outside eyes and ears, and makes you aware of where you're falling short.

In other words, the coach provides objective feedback and structure.

Commenting on what it's like to have a surgical coach, Gawande offers:

Osteen (Gawande's coach) watched, silent and blank-faced the entire time, taking notes. My cheeks burned; I was mortified. I wished I'd never asked him along. I tried to be rational about the situation—the patient did fine. But I had let Osteen see my judgment fail; I'd let him see that I may not be who I want to be.

This is why it will never be easy to submit to coaching, especially for those who are well along in their career. I'm ostensibly an expert. I'd finished long ago with the days of being tested and observed. I am supposed to be past needing such things. Why should I expose myself to scrutiny and fault-finding?

It takes a special person to bring in a coach mid-career and subject themselves to "scrutiny and fault-finding."

Maybe you're thinking, I don't need a coach because "I'm my own worst critic." That may be the case, however, it is really hard, but not impossible, to be your own (objective) coach. You need structure and *objective* feedback.

(I don't want to get into too much nuance, but you also have to think about feedback systems. Part of deliberate practice is immediate and constant feedback. This enables course correction. The time-to-feedback can derail deliberate practice if it's too long.)

4. Exercise

In [Brain Rules](#), John Medina [explores the relationship between exercise and mental alertness](#):

Just about every mental test possible was tried. No matter how it was measured, the answer was consistently yes: A lifetime of exercise can result in a sometimes astonishing elevation in cognitive performance, compared with those who are sedentary. Exercisers outperform couch potatoes in tests that measure long-term memory, reasoning, attention, problem-solving, even so-called fluid-intelligence tasks. These tasks test the ability to reason quickly and think abstractly, improvising off previously learned material in order to solve a new problem. Essentially, exercise improves a whole host of abilities prized in the classroom and at work.

5. Rest

Taking time to rest won't make you a slacker. While the corporate culture of "back-to-back" meetings from 9-5 may seem "cool" it is actually crazy. Rest is a critical component of creating and sustaining excellence.

26. The Impoverishment of Attention

"While the link between attention and excellence remains hidden most of the time, it ripples through almost everything we seek to accomplish."

Focus matters enormously for success in life and yet we seem to give it little attention. Daniel Goleman's book, *Focus: The Hidden Driver of Excellence*, explores the power of attention. "Attention works much like a muscle," he writes, "use it poorly and it can wither; work it well and it grows."

To get the results we want in life, Goleman argues we need three kinds of focus: inner, other, and outer.

Inner focus attunes us to our intuitions, guiding values, and better decisions. Other focus smooths our connections to the people in our lives. And outer focus lets us navigate in the larger world. A (person) tuned out of his internal world will be rudderless; one blind to the world of others will be clueless; those indifferent to the larger systems within which they operate will be blindsided.

How we deploy attention shapes what we see. Or as Yoda says, "Your focus is your reality."

Goleman argues that, despite the advantages of everything being only a click away, our attention span is suffering.

An eighth-grade teacher tells me that for many years she has had successive classes of students read the same book, Edith Hamilton's Mythology. Her students have loved it—until five years or so ago. "I started to see kids not so excited— even high-achieving groups could not get engaged with it," she told me. "They say the reading is too hard; the sentences are too complicated; it takes a long time to read a page."

She wonders if perhaps her students' ability to read has been somehow compromised by the short, choppy messages they get in texts. One student confessed he'd spent two thousand hours in the last year playing video games. She adds, "It's hard to teach comma rules when you are competing with World of WarCraft."

Here is a telling story. I was in a coffee shop just the other day and I noticed that when two people were having a conversation they couldn't go more than a few minutes without picking up their phone. Our inability to resist checking email, Facebook, and Twitter rather than focus on the here and now leads to a real-life out-of-office. Sociologist Erving Goffman, calls this "away," which tells other people "I'm not interested" in you right now. We continually fight distractions. From televisions on during supper, text messages, emails, phone calls ... you get the picture. This is one reason I've changed my media consumption habits.

It feels like we're going through life in a state of "continuous partial attention." We're there but not really there. Unaware of where we place our attention. Unconscious about how we live.

I once worked with the CEO of a private organization. We often discussed board meetings, agendas, and other areas of time allocation. I sensed a disconnect between where he wanted to spend his time and what he actually spent time on.

To verify, I went back over the last year of board meetings and categorized each scheduled agenda item. I found a substantial mismatch; he was spending a great deal of time on issues he thought were not important. In fact, the 'scheduled time' was almost the complete inverse of what he wanted to focus on.

Goleman also points to some of the implications of our modern world.

The onslaught of incoming data leads to sloppy shortcuts, like triaging email by heading, skipping much of voice mails, skimming messages and memos. It's not just that we've developed habits of attention that make us less effective, but that the weight of messages leaves us too little time simply to reflect on what they really mean.

In 1977, foreseeing what was going to happen, the Nobel-winning economist Herbert Simon wrote:

What information consumes is rather obvious: it consumes the attention of its recipients. Hence a wealth of information creates a poverty of attention, and a need to allocate that attention efficiently among the overabundance of information sources that might consume it.

William James, a pioneer of modern psychology, defined attention as “the sudden taking possession by the mind, in clear and vivid form, of one of what seems several simultaneously possible objects or trains of thought.”

We naturally focus when we're lost. Imagine for a second the last time you were driving in your car without your GPS and you got lost. Think back to the first thing you did in response. I bet you turned off the radio so you could increase your focus.

Goleman, paraphrasing research, argues there are two main varieties of distractions: sensory and emotional.

The sensory distractors are easy: as you read these words you're tuning out (our sponsor and all of the text on the right). Or notice for a moment the feeling of your tongue against your upper palate—just one of an endless wave of incoming stimuli your brain weeds out from the continuous wash of background sounds, shapes and colors, tastes, smells, sensations, and on and on.

More daunting is the second variety of lures: emotionally loaded signals. While you might find it easy to concentrate on answering your email in the hubbub of your local coffee shop, if you should overhear someone mention your name (potent emotional bait, that) it's almost impossible to tune out the voice that carries it—your attention reflexively alerts to hear what's being said about you. Forget that email. The dividing line between fruitless rumination and productive reflection lies in whether or not we come up with some tentative solution or insight and then can let those distressing thoughts go—or if, on the other hand, we just keep obsessing over the same loop of worry.

The more our focus gets disrupted, the worse we do.

To focus we must tune out emotional distractions. But not at all costs. The power to disengage focus is also important.

That means those who focus best are relatively immune to emotional turbulence, more able to stay unflappable in a crisis and to keep on an even keel despite life's emotional waves.

Failure to drop one focus and move on to others can, for example, leave the mind lost in repeating loops of chronic anxiety. At clinical extremes it means being lost in helplessness, hopelessness, and self-pity in depression; or panic and catastrophizing in anxiety disorders; or countless repetitions of ritualistic thoughts or acts (touch the door fifty times before leaving) in obsessive-compulsive disorder. The power to disengage our attention from one thing and move it to another is essential for well-being.

We've all seen what a strong selective focus looks like. It's the couple in the coffee shop mentioned above, eyes locked, who fail to realize they are not alone.

It should come as no surprise that we learn best with focused attention.

As we focus on what we are learning, the brain maps that information on what we already know, making new neural connections. If you and a small toddler share attention toward something as you name it, the toddler learns that name; if her focus wanders as you say it, she won't.

When our mind wanders off, our brain activates a host of brain circuits that chatter about things that have nothing to do with what we're trying to learn. Lacking focus, we store no crisp memory of what we're learning.

Goleman goes on to discuss how we connect what we read to our mental models, which is the heart of learning.

As we read a book, a blog, or any narrative, our mind constructs a mental model that lets us make sense of what we are reading and connects it to the universe of such models we already hold that bear on the same topic.

If we can't focus we'll have more holes in our understanding. (To find holes in your understanding, try the Feynman Technique, which was actually an invention of George Eliot's but I'll save that for another day.)

When we read a book, our brain constructs a network of pathways that embodies that set of ideas and experiences. Contrast that deep comprehension with the interruptions and distractions that typify the ever-seductive Internet.

The continuous onslaught of texts, meetings, videos, music, email, Twitter, Facebook, and more is the enemy of understanding. The key, argues Nicolas Carr, author of *The Shallows: What the Internet Is Doing to Our Brains*, is "deep reading." And the internet is making this nearly impossible.

There is, however, perhaps no skill better than deep and focused thought. "The more information that's out there," says Tyler Cowen, author of *Average Is Over: Powering America Beyond the Age of the Great Stagnation*, "the greater the returns to just being willing to sit down and apply yourself. Information isn't what's scarce; it's the willingness to do something with it." Deep thought must be learned. In order to do that, however, we must tune out most of the distractions and focus.

Goleman reminds us that some of this too was foreseen.

Way back in the 1950s the philosopher Martin Heidegger warned against a looming "tide of technological revolution" that might "so captivate, bewitch, dazzle, and beguile man that calculative thinking may someday come to be ... the only way of thinking." That would come at the loss of "meditative thinking," a mode of reflection he saw as the essence of our humanity.

I hear Heidegger's warning in terms of the erosion of an ability at the core of reflection, the capacity to sustain attention to an ongoing narrative. Deep thinking demands sustaining a focused mind. The more distracted we are, the more shallow our reflections; likewise, the shorter our reflections, the more trivial they are likely to be. Heidegger, were he alive today, would be horrified if asked to tweet.

29. Learning by Thinking: How Reflection Aids Performance

“By three methods we may learn wisdom: First, by reflection, which is noblest; Second, by imitation, which is easiest; and third, by experience, which is the bitterest.”

— Confucius

It's been a while since I covered an academic paper. But one by Giada Di Stefano, Francesca Gino, Gary Pisano, and Bradley Staats on the role reflection plays in learning is fascinating.

Learning plays an important role in everything. This is why the concept of learning has gotten a lot of attention from scholars. You can argue that today's "Knowledge economy" further accelerates the pace of learning; things are changing and we need to keep up. This, the authors argue, makes our experience more productive and builds our confidence "in the ability to achieve a goal," which further translates into "higher rates of learning."

What is learning?

"Learning," they write, "is defined as a lasting change in knowledge generated by experience."

(There are) two types of learning, which are based on the source of such experience: direct learning from one's own experience and indirect learning from the experience of others.

Most research tends to focus on "learning by doing" whereas Farnam Street is more oriented towards indirect learning.

In Learning by Thinking: How Reflection Aids Performance the authors "take a less traveled road and focus on how individual learning can be augmented when individuals can not only "do" but also "think" about what they have been doing." That is, we learn better when we couple learning by doing with reflection — "that is, the intentional attempt to synthesize, abstract, and articulate the key lessons taught by experience."

This, the authors argue, makes our experience more productive and builds our confidence "in the ability to achieve a goal," which further translates into "higher rates of learning."

Dual Process Theory

The argument is based on the dual-process theory, which suggests:

"... the existence of two systems of thought that underlie intuitive and reflective processing, often referred to as type 1 and type 2, respectively ... We propose a dual-process learning model in which the automatic, unconscious process of learning generated from experience is coupled with the controlled, conscious attempt at learning."

Findings

Our findings suggest that reflection is a powerful mechanism by which experience is translated into learning. In particular, we find that individuals perform significantly better on subsequent tasks when they think about what they learned from the task they completed. Interestingly, we do not observe an additional boost in performance when individuals share the insights from their reflection efforts with others. Results of mediation analyses further show that the improvement in performance observed when individuals are learning by thinking is explained by increased self-efficacy generated by reflection.

Interesting, my system for remembering what I read has intuitive roots built around reflection.

General Discussion

Though some organizations are increasingly relying on some group reflection (e.g., "after-action reports"), there has been almost no effort to encourage individuals to reflect, and people often fail to engage in self-reflection themselves. Though reflection entails the high opportunity cost of one's time, we argue and show that reflecting after completing tasks is no idle pursuit: it can powerfully enhance the learning process. Learning, we find, can be augmented if one deliberately focuses on thinking about what one has been doing. In

addition to showing a significant performance differential when comparing learning-by-doing alone to learning-by-doing coupled with reflection, we also demonstrate that the effect of reflection on learning is mediated by greater self-efficacy.

This part was also interesting. What matters is reflection, not why you are reflecting. Across our studies, we also included a condition in which people shared their reflections with others. Interestingly, our results show that while sharing one's learning improves one's subsequent performance, the value of sharing is no different than that of reflecting and keeping one's thoughts to oneself.

Implications

The implications here support much that we've already covered on Farnam Street.

"... taking time away from training and reallocating that time to reflection actually improved individual performance."

Learning and decision journals encourage reflection and thus knowledge.

Companies often use tools such as learning journals as a way to encourage reflection in training and regular operations.

It's all about smarter, not harder.

"Our personal experience is that individuals of all ages may not treat these exercises with much seriousness."

So if you want a leg up, pay attention and take this seriously.

30. To Learn, Retrieve

Mike Ebersold is a neurosurgeon. In neurosurgery and indeed life there is an essential kind of learning that only comes from reflection on personal experience.

In the book Make It Stick: The Science of Successful Learning, the authors capture Ebersold's description:

A lot of times something would come up in surgery that I had difficulty with, and then I'd go home that night thinking about what happened and what could I do, for example, to improve the way a suturing went. How can I take a bigger bite with my needle, or a smaller bite, or should the stitches be closer together? What if I modified it this way or that way? Then the next day back, I'd try that and see if it worked better. Or even if it wasn't the next day, at least I've thought through this, and in so doing I've not only revisited things that I learned from lectures or from watching others performing surgery but also I've complemented that by adding something of my own to it that I missed during the teaching process.

"Reflection," Ebersold says, "can involve several cognitive activities that lead to stronger learning: retrieving knowledge and earlier training from memory, connecting these to new experiences, and visualizing and mentally rehearsing what you might do differently next time."

The authors of Make It Stick continue:

To make sure the new learning is available when it's needed, Ebersold points out, "you memorize the list of things that you need to worry about in a given situation: steps A, B, C, and D," and you drill on them. Then there comes a time when you get into a tight situation and it's no longer a matter of thinking through the steps, it's a matter of reflexively taking the correct action.

"Unless you keep recalling this maneuver," Ebersold notes, "it will not become a reflex. Like a race car driver in a tight situation or a quarterback dodging a tackle, you've got to act out of reflex before you've even had time to think. Recalling it over and over, practicing it over and over. That's just so important."

The Testing Effect

The power of retrieval as a learning tool is known among psychologists as the testing effect. In its most common form, testing is used to measure learning and assign grades in school, but we've long known that the act of retrieving knowledge from memory has the effect of making that knowledge easier to call up again in the future.

Francis Bacon and William James also wrote about this phenomenon. Retrieval makes things stick better than re-exposure to the original material. This is the testing effect.

To be most effective, retrieval must be repeated again and again, in spaced out sessions so that the recall, rather than becoming a mindless recitation, requires some cognitive effort. Repeated recall appears to help memory consolidate into a cohesive representation in the brain and to strengthen and multiply the neural routes by which the knowledge can later be retrieved. In recent decades, studies have confirmed what Mike Ebersold and every seasoned quarterback, jet pilot, and teenaged texter knows from experience—that repeated retrieval can so embed knowledge and skills that they become reflexive: the brain acts before the mind has time to think.

Learning or Just Recalling Information?

In 2010 the New York Times reported on a scientific study that showed that students who read a passage of text and then took a test asking them to recall what they had read retained an astonishing 50 percent more of the information a week later than students who had not been tested.

This would seem like good news, but here's how it was greeted in many online comments:

- "Once again, another author confuses learning with recalling information."

- *“I personally would like to avoid as many tests as possible, especially with my grade on the line. Trying to learn in a stressful environment is no way to help retain information.”*
- *“Nobody should care whether memorization is enhanced by practice testing or not. Our children cannot do much of anything anymore.”*

Forget memorization, many commenters argued; education should be about high-order skills. Hmmm. If memorization is irrelevant to complex problem solving, don't tell your neurosurgeon. The frustration many people feel toward standardized, “dipstick” tests given for the sole purpose of measuring learning is understandable, but it steers us away from appreciating one of the most potent learning tools available to us. Pitting the learning of basic knowledge against the development of creative thinking is a false choice. Both need to be cultivated. The stronger one's knowledge about the subject at hand, the more nuanced one's creativity can be in addressing a new problem. Just as knowledge amounts to little without the exercise of ingenuity and imagination, creativity absent a sturdy foundation of knowledge builds a shaky house.

The Takeaway

Practice at retrieving new knowledge or skill from memory is a potent tool for learning and durable retention. This is true for anything the brain is asked to remember and call up again in the future—facts, complex concepts, problem-solving techniques, motor skills. Effortful retrieval makes for stronger learning and retention. We're easily seduced into believing that learning is better when it's easier, but the research shows the opposite: when the mind has to work, learning sticks better. The greater the effort to retrieve learning, provided that you succeed, the more that learning is strengthened by retrieval. After an initial test, delaying subsequent retrieval practice is more potent for reinforcing retention than immediate practice, because delayed retrieval requires more effort. Repeated retrieval not only makes memories more durable but produces knowledge that can be retrieved more readily, in more varied settings, and applied to a wider variety of problems.

While cramming can produce better scores on an immediate exam, the advantage quickly fades because there is much greater forgetting after rereading than after retrieval practice. The benefits of retrieval practice are long-term.

Simply including one test (retrieval practice) in a class yields a large improvement in final exam scores, and gains continue to increase as the frequency of classroom testing increases.

Testing doesn't need to be initiated by the instructor. Students can practice retrieval anywhere; no quizzes in the classroom are necessary. Think flashcards—the way second graders learn the multiplication tables can work just as well for learners at any age to quiz themselves on anatomy, mathematics, or law. Self-testing may be unappealing because it takes more effort than rereading, but as noted already, the greater the effort at retrieval, the more will be retained.

Students who take practice tests have a better grasp of their progress than those who simply reread the material. Similarly, such testing enables an instructor to spot gaps and misconceptions and adapt instruction to correct them.

Giving students corrective feedback after tests keeps them from incorrectly retaining material they have misunderstood and produces better learning of the correct answers. Students in classes that incorporate low-stakes quizzing come to embrace the practice. Students who are tested frequently rate their classes more favorable.

31. The Simplest Way to Achieve Simplicity is Through Thoughtful Reduction

A close friend of mine argues that while we love the first part of Einstein's quote, "Everything should be made as simple as possible," we ignore the second part "but not simpler," which is the essence of Occam's Razor. This article is about how we can achieve simplicity through thoughtful reduction.

"Everything should be made as simple as possible, but not simpler."

— Einstein

After a bit of reflection, on twitter, I wrote: *"You don't fully understand something until you can simplify it. But if all you do is simplify it, you don't understand it."*

The complexity of "but not simpler" is where we struggle.

This is where our brain struggles and tries to avoid work. The struggle is where the real learning comes from.

We are pattern matching creatures — once we find a solution that works, we close our minds to alternative ideas.

A key element of simplicity and understanding is the thoughtful reduction of the unnecessary.

An inversion if you will. And yet one I wish more organizations would consider. While it's counter-intuitive, subtraction is often more powerful than addition.

In The Laws of Simplicity, John Maeda writes:

The easiest way to simplify a system is to remove functionality. Today's DVD, for instance, has too many buttons if all you want to do is play a movie. A solution could be to remove the buttons for Rewind, Forward, Eject, and so forth until only one button remains: Play. But what if you want to replay a favorite scene? Or pause the movie while you take that all-important bathroom break? The fundamental question is, where's the balance between simplicity and complexity?

**HOW SIMPLE CAN
YOU MAKE IT?**

**HOW COMPLEX DOES
IT HAVE TO BE?**

On the one hand, you want a product or service to be easy to use; on the other hand you want it to do everything that a person might want it to do.

The process of reaching an ideal state of simplicity can be truly complex, so allow me to simplify it for you. The simplest way to achieve simplicity is through thoughtful reduction. When in doubt, just remove. But be careful of what you remove.

It's not about removing for the sake of removing.

When it is possible to reduce a system's functionality without significant penalty, true simplification is realized. When everything that can be removed is gone, a second battery of methods can be employed. I call these methods SHE: SHRINK, HIDE, EMBODY.

[...]

Simplicity is about the unexpected pleasure derived from what is likely to be insignificant and would otherwise go unnoticed.

If you're short on time you can stop here. If you're interested in SHE (Shrink, Hide, Embody) keep reading.

Size matters.

The smaller the object, the more forgiving we can be when it misbehaves.

Making things smaller doesn't make them necessarily better, but when made so we tend to have a more forgiving attitude towards their existence. A larger-than-human-scale object demands its rightful respect, whereas a tiny object can be something that deserves our pity. When comparing a kitchen spoon to a construction bulldozer the larger scale of the vehicle instills fear, while the rounded utensil appears harmless and inconsequential. The bulldozer can run you over and end your life, but if the spoon were to fall on top of you, your life would likely be spared. Guns, mace cannisters, and little karate experts of course are the exception to this rule of "fear the large, endear the small."

Technology is SHRINK-ing.

The computational power of a machine that sixty years ago weighed 60,000 pounds and occupied 1,800 square feet can now be packed onto a sliver of metal less than a tenth the size of the nail on your pinkie. Integrated circuit (IC) chip technology-commonly referred to as "computer chips"-allows far greater complexity at a much tinier scale. IC chips lie at the heart of the problem of complex devices today as they enable increasingly smaller devices to be created. A kitchen spoon and a mobile phone can share the exact same physical dimensions, yet the many IC's embedded inside the phone make the device easily more complex than the bulldozer-so looks can be deceiving.

Thus while IC's are a primary driver of complexity in modern day objects, they also enable the ability to shrink a frighteningly complex machine to the size of a cute little gumbdrop.

The smaller the object is, the lower the expectations; the more IC's that are inside, the greater the power. In this age of wireless technology that connects the IC inside the phone with all the computers in the world, power has now become absolute. There is no turning back to the age when large objects were complex and small objects were simple.

[...]

Lessening the inevitable complicating blow of these technologies by way of SHRINK may seem like a form of deception, which it is. But anything that can make the medicine of complexity go down easier is a form of simplicity, even when it is an act of deceit.

SHE: HIDE

When all features that can be removed have been, and a product has been made slim, light, and thin, it's time for the second method: HIDE the complexity through brute-force methods. A classical example of this technique is the Swiss army knife. Only the tool you wish to use is exposed, while the other blades and drivers are hidden.

[...]

Hiding complexity through ingenious mechanical doors or tiny display screens is an overt form of deception. If the deceit feels less like malevolence, more like magic, then hidden complexities become more of a treat than a nuisance. The ear-catching "click" when opening a Motorola Razr cell phone or the cinematic performance of an on-screen visual in Apple's Mac OS X creates the satisfaction of owning the power to will complexity from simplicity. Thus complexity becomes a switch that the owner can choose to flip into action on their own terms, and not by their device's will.

SHRINK-ing an object lowers expectations, and the hiding of complexities allows the owner to manage the expectations himself. Technology creates the problem of complexity, but also affords new materials and methods for the design of our relationship with complexities that shall only continue to multiply.

SHE: EMBODY

As features go into hiding and products shrink, it becomes ever more necessary to embed the object with a sense of the value that is lost after HIDE and SHRINK. Consumers will only be drawn to the smaller, less functional product if they perceive it to be more valuable than a bigger version of the product with more features. Thus the perception of quality becomes a critical factor when making the choice of less over more.

And in contrast to Sanjay Bakshi's pragmatic take on the luxury goods business, Maeda takes a different approach.

Embodying an object with properties of real quality is the basis of the luxury goods industry and is rooted in their use of precious materials and exquisite craftsmanship. Relatedly, a designer of Ferrari cars once told me that a Ferrari has fewer parts than a common car, but the parts themselves are significantly better than anything else on this earth. This elegant tale of construction uses the simple philosophy that if good parts can make a great product, incredible parts can lead to a legendary one.

[...]

It is necessary to advertise qualities that cannot be conveyed implicitly, especially when the message of embodiment simply tells the truth.

The first law can be summed up as:

Lessen what you can and conceal everything else without losing the sense of inherent value. EMBODY-ing a greater sense of quality through enhanced materials and other messaging cues is an important subtle counterbalance to SHRINK-ing and HIDEing the directly understood aspects of a product. Design, technology, and business work in concert to realize the final decisions that will lead to how much reduction in a product is tolerable, and how much quality it will embody in spite of its reduced state of being. Small is better when SHE'd.

32. Lifelong Learning

Your education shouldn't end when your schooling does. If you want to get an edge in life, you must be constantly learning, not coasting along on what you already know. Lifelong learning requires the ability to reflect on your mistakes, a lot of reading, and testing what you know.

"By three methods we may learn wisdom: First, by reflection, which is noblest; Second, by imitation, which is easiest; and third by experience, which is the bitterest."

— Confucius

I'm a huge fan of Laurence Endersen's book: *Pebbles of Perception: How a Few Good Choices Make All The Difference*. I think it deserves to be on the shelf of every knowledge seeker in the world.

There is a chapter in the book on lifelong learning.

When we are captain of our own ship, life can be a wonderful continuous voyage of discovery. Yet we frequently pigeonhole our learning and discovery into limiting discrete blocks. There are the childhood years, filled with exploration and getting to know the world around us at a sensory level. The early school years follow, during which we are introduced to reading and writing. Middle school years bring a range of core subjects and some people will finish up the formal part of their education with university-level learning. Then we add some work experience and attain a certain level of competence. From this perch we coast pretty well. It's like driving. How many of us are getting better at driving? All of those hours behind the wheel are not deliberate practice. If you consider the product of the modern knowledge worker to be decisions, all of this coasting without getting better should concern you.

Lifelong Learning

The incentives to follow a path of lifelong learning are not easily apparent.

When assessing our competence in any particular discipline, we can place our level of ability somewhere along a continuum moving from ignorance, to conversational competence, to operational competence, then towards proficiency, and finally all the way to mastery. For most of us, if we get to operational competence in our main career area we are happy enough. We can get by and we don't have to expend too much energy continuously learning. We become what I call flat-line learners. For the flat-line learner the learning curve might look something like this:

And yet, Endersen argues that if we pursue a path of lifelong learning our path more closely resembles this:

You could even make an argument that lifelong learning puts you on a non-linear path but I'll leave that for you to think about.

The question as to why everyone doesn't want to become a lifelong learner remains.

It may boil down to choices and priorities. It is easy to be drawn towards passive entertainment, which requires less from us, over more energetic, active understanding. Inconvenience might be an alibi: "I don't have time for continuous learning as I am too busy with real life". But that excuse doesn't withstand close scrutiny, as experiences (coupled with reflection) can be the richest of all sources of investigation and discovery. Why not make a conscious decision to learn something new every day? No matter how small the daily learning, it is significant when aggregated over a lifetime. Resolving early in life to have a continuous learning mindset is not only more interesting than the passive alternative, it is also remarkably powerful. Choosing lifelong learning is one of the few good choices that can make a big difference in our lives, giving us an enormous advantage when practiced over a long period of time.

Reflection

The ignorant man can't learn from his own mistake and the fool can't learn from the mistakes of others. These are the primary ways we learn: Through our own experiences and through the experiences of others.

While both avenues have their place, there is no substitute for direct learning through experience – which we enhance through reflection. The process of thoughtful reflection makes our experiences more concrete, and helps with future recall and understanding. Reflecting about what we learned, how we felt, how we and others behaved, and what interests were at play, hardwires the learning in our brain and gives us a depth of context and relevance that would otherwise be absent.

Even if it were desirable, which it's not, there simply is not enough time to learn everything we need to know through direct experience.

Reading

"Reading," writes Endersen, "is the foundation of indirect learning." Learning how to read and finding time to read are two of the easiest and best changes you can make if you want to pursue lifelong learning.

Many read for entertainment. Some read for information. Too few read for understanding. Adler's book (How To Read a Book) is concerned with reading to understand. Being widely read is not the same as being well read. The more effort and skill we put into reading, the greater our understanding.

The Feynman Technique

As for testing whether we really understand something after we've read it, there is a powerful and elegant technique called the Feynman Technique.

Step 1. Choose the topic or concept that you are trying to understand. Take a blank piece of paper and write the name of the topic at the top.

Step 2. Assume you're teaching the topic to someone else. Write out a clear explanation of the topic, as if you were trying to teach it. A great way to learn is to teach. You identify gaps in your knowledge very quickly when trying to explain something to someone else in simple terms.

Step 3. If you get bogged down, go back to the source materials. Keep going back until you can explain the concept in its most basic form.

Step 4. Go back and simplify your language. The goal is to use your own words, not the words of the source material. Overly elaborate language is often a sure sign that you don't fully understand the concept. Use simple language and build on that with a clear analogy. An example that springs to mind is Warren Buffet's explanation of compound interest (i.e., interest earned on interest), when he likened it to a snowball that gathers snow as it rolls down a hill.

Lifelong learning is a better path than flat-line learning.

Savour experiences as opportunities to learn. Reflect on your experiences. Read regularly. Learn how to read for understanding. Know how to test whether you really understand something by demonstrating that you could teach it in simple terms with a clear analogy.

33. Steven Pinker: What a Broad Education Should Entail

Harvard's biologist/psychologist Steven Pinker is one of my favorites, even though I'm just starting to get into his work.

What makes him great is not just his rational mind, but his multidisciplinary approach. He pulls from many fields to make his (generally very good) arguments. And he's a rigorous scientist in his own field, even before we get to his ability to synthesize.

I first encountered Pinker in reading Poor Charlie's Almanack: Charlie Munger gives him the edge over Noam Chomsky and others in the debate over whether the capacity for language has been "built into" our DNA through natural selection.

Pinker wrote the bestseller, The Language Instinct, in which he argued that the capacity for complex language is innate. We develop it, of course, throughout our lives, but it's in our genes from the beginning (an idea that has since been criticized).

Pinker went on to write books with modest titles like How the Mind Works, The Blank Slate: The Modern Denial of Human Nature, and The Better Angels of Our Nature: Why Violence Has Declined. The latter is a controversial one: Bill Gates loves it, Nassim Taleb hates it. You'll have to make up your own mind.

The reason for writing about Pinker is that, while re-reading William Deresiewicz's brilliant speech, Solitude and Leadership, I noticed that he had an extremely popular piece about not sending your kids to Ivy League schools. It's an interesting argument, though I'm not sure I agree with all of it.

A little Googling told me that Pinker, himself a professor at an Ivy League school, responded with an even better piece on why Deresiewicz was imprecise in his criticisms and anecdotes.

I was fascinated most by Pinker's discussion of what an elite education *should* entail. This tells you a lot about his mind:

This leads to Deresiewicz's second goal, "building a self," which he explicates as follows: "it is only through the act of establishing communication between the mind and the heart, the mind and experience, that you become an individual, a unique being—a soul." Perhaps I am emblematic of everything that is wrong with elite American education, but I have no idea how to get my students to build a self or become a soul. It isn't taught in graduate school, and in the hundreds of faculty appointments and promotions I have participated in, we've never evaluated a candidate on how well he or she could accomplish it. I submit that if "building a self" is the goal of a university education, you're going to be reading anguished articles about how the universities are failing at it for a long, long time. I think we can be more specific. It seems to me that educated people should know something about the 13-billion-year prehistory of our species and the basic laws governing the physical and living world, including our bodies and brains. They should grasp the timeline of human history from the dawn of agriculture to the present. They should be exposed to the diversity of human cultures, and the major systems of belief and value with which they have made sense of their lives. They should know about the formative events in human history, including the blunders we can hope not to repeat. They should understand the principles behind democratic governance and the rule of law. They should know how to appreciate works of fiction and art as sources of aesthetic pleasure and as impetuses to reflect on the human condition.

On top of this knowledge, a liberal education should make certain habits of rationality second nature. Educated people should be able to express complex ideas in clear writing and speech. They should appreciate that objective knowledge is a precious commodity, and know how to distinguish vetted fact from superstition, rumor, and unexamined conventional wisdom. They should know how to reason logically and statistically, avoiding the fallacies and biases to which the untutored human mind is vulnerable. They should

think causally rather than magically, and know what it takes to distinguish causation from correlation and coincidence. They should be acutely aware of human fallibility, most notably their own, and appreciate that people who disagree with them are not stupid or evil. Accordingly, they should appreciate the value of trying to change minds by persuasion rather than intimidation or demagoguery.

I believe (and believe I can persuade you) that the more deeply a society cultivates this knowledge and mindset, the more it will flourish. The conviction that they are teachable gets me out of bed in the morning. Laying the foundations in just four years is a formidable challenge. If on top of all this, students want to build a self, they can do it on their own time.

If this seems familiar to some of you, that's because it very closely parallels thoughts by Charlie Munger, who has argued many times for something similar in his demand for multidisciplinary worldly wisdom. We must learn the big ideas from the big disciplines. Notice the buckets Pinker talks about: 13 billion years of organic and inorganic history, 10,000 years of human culture, hundreds of years of modern civilization. These are the most reliable forms of wisdom.

So if the education system won't do it for you, the job must be done anyway. Pinker and Munger have laid out the kinds of things you want to go about learning. Don't let the education system keep you from having a real education. Learn how to think. Figure out how to spend more time reading. When you do, focus on the most basic and essential wisdom — including the lessons from history.

Article Summary

- If the goal of university education is to build the self, we will be disappointed.
- Rather, the goal of university education should be to: (1) give people an idea of our prehistory; (2) the basic laws governing the physical and living worlds; (3) the timeline of human history; (4) multiple cultures; (5) the formative events in human history; (6) the principles behind democracy and the rule of law; (7) read the great works of fiction and appreciate the great works of art as sources of aesthetic pleasure and reflections on the human condition; (8) make the habits of rationality second nature; (9) learn how to express ideas clearly in writing and talking; (10) appreciate objective knowledge; (11) learn how to reason and think statistically; (12) think causally rather than magically and understand the difference between causation and correlation and coincidence; and (13) appreciate human fallibility, most notably our own.
- You can't blame the education system if you don't get this education, it's up to you.

34. Academic Economics: Strengths and Weaknesses, Considering Interdisciplinary Needs by Charlie Munger

This is the full text of Charlie Munger's Herb Kay Memorial Lecture, 'Academic Economics: Strengths and Weaknesses, after Considering Interdisciplinary Needs,' at the University of California at Santa Barbara, 2003.

If you don't know how to think, you'll always
be a one-legged man in an ass-kicking contest

Transcript

I've outlined some remarks in a rough way, and after I'm finished talking from that outline, I'll take questions as long as anybody can endure listening until they drag me away to wherever else I'm supposed to go.

As you might guess, I agreed to do this because the subject of getting the soft sciences so they talked better to each other has been one that has interested me for decades. And, of course, economics is in many respects the queen of the soft sciences. It's expected to be better than the rest. It's my view that economics is better at the multi-disciplinary stuff than the rest of the soft science. And it's also my view that it's still lousy, and I'd like to discuss this failure in this talk. As I talk about strengths and weaknesses in academic economics, one interesting fact you are entitled to know is that I never took a course in economics. And with this striking lack of credentials, you may wonder why I have the chutzpah to be

up here giving this talk. The answer is I have a black belt in chutzpah. I was born with it. Some people, like some of the women I know, have a black belt in spending. They were born with that. But what they gave me was a black belt in chutzpah.

But I come from two peculiar strands of experience that may have given me some useful economic insights. One is Berkshire Hathaway and the other is my personal educational history.

Berkshire, of course, has finally gotten interesting. When Warren took over Berkshire, the market capitalization was about ten million dollars. And forty-something years later, there are not many more shares outstanding now than there were then, and the market capitalization is about a hundred billion dollars, ten thousand for one. And since that has happened, year after year, in kind of a grind-ahead fashion, with very few failures, it eventually drew some attention, indicating that maybe Warren and I knew something useful in microeconomics.

Non-use of Efficient Market Theory at Berkshire

For a long time there was a Nobel Prize-winning economist who explained Berkshire Hathaway's success as follows:

First, he said Berkshire beat the market in common stock investing through one sigma of luck, because nobody could beat the market except by luck. This hard-form version of efficient market theory was taught in most schools of economics at the time. People were taught that nobody could beat the market. Next, the professor went to two sigmas, and three sigmas, and four sigmas, and when he finally got to six sigmas of luck, people were laughing so hard he stopped doing it.

Then he reversed the explanation 180 degrees. He said, "No, it was still six sigmas, but it was six sigmas of skill." Well, this very sad history demonstrates the truth of Benjamin Franklin's observation in Poor Richard's Almanac. If you would persuade, appeal to interest and not to reason. The man changed his view when his incentives made him change it, and not before.

I watched the same thing happen at the Jules Stein Eye Institute at UCLA. I asked at one point, why are you treating cataracts only with a totally obsolete cataract operation? And the man said to me, "Charlie, it's such a wonderful operation to teach." (Laughter). When he stopped using that operation, it was because almost all the patients had voted with their feet. Again, appeal to interest and not to reason if you want to change conclusions.

Well, Berkshire's whole record has been achieved without paying one ounce of attention to the efficient market theory in its hard form. And not one ounce of attention to the descendants of that idea, which came out of academic economics and went into corporate finance and morphed into such obscenities as the capital asset pricing model, which we also paid no attention to. I think you'd have to believe in the tooth fairy to believe that you could easily outperform the market by seven-percentage points per annum just by investing in high volatility stocks.

Yet, believe it or not, like the Jules Stein doctor, people once believed this stuff. And the belief was rewarded. And it spread. And many people still believe it. But Berkshire never paid any attention to it. And now I think the world is coming our way and the idea of perfection in all market outcomes is going the way of the DoDo.

It was always clear to me that the stock market couldn't be perfectly efficient, because as a teenager, I'd been to the racetrack in Omaha where they had the parimutuel system. And it was quite obvious to me that if the house's take, the croupier's take, was 17%, some people consistently lost a lot less than 17% of all their bets, and other people consistently lost more than 17% of all their bets. So the parimutuel system in Omaha had no perfect efficiency. And so I didn't accept the argument that the stock market was always perfectly efficient in creating rational prices.

Indeed, there's been some documented cases since, of people getting so good at understanding horses and odds, that they actually are able to beat the house in off-track

betting. There aren't many people who can do that, but there are a few people in America who can.

Personal Multidisciplinary Education

Next, my personal education history is interesting because its deficiencies and my peculiarities eventually created advantages. For some odd reason, I had an early and extreme multidisciplinary cast of mind. I couldn't stand reaching for a small idea in my own discipline when there was a big idea right over the fence in somebody else's discipline. So I just grabbed in all directions for the big ideas that would really work. Nobody taught me to do that; I was just born with that yen. I also was born with a huge craving for synthesis. And when it didn't come easily, which was often, I would rag the problem, and then when I failed I would put it aside and I'd come back to it and rag it again. It took me 20 years to figure out how and why the Reverend Moon's conversion methods worked. But the psychology departments haven't figured it out yet, so I'm ahead of them.

But anyway, I have this tendency to want to rag the problems. Because WW II caught me. I drifted into some physics, and the Air Corps sent me to Caltech where I did a little more physics as part of being made into a meteorologist. And there, at a very young age, I absorbed what I call the fundamental full attribution ethos of hard science. And that was enormously useful to me. Let me explain that ethos.

Under this ethos, you've got to know all the big ideas in all the disciplines less fundamental than your own. You can never make any explanation, which can be made in a more fundamental way, in any other way than the most fundamental way. And you always take with full attribution to the most fundamental ideas that you are required to use. When you're using physics, you say you're using physics. When you're using biology, you say you're using biology. And so on and so on. I could early on see that that ethos would act as a fine organizing system for my thoughts. And I strongly suspected that it would work really well in the soft sciences as well as the hard sciences, so I just grabbed it and used it all through my life in soft science as well as hard science. That was a very lucky idea for me. Let me explain how extreme that ethos is in hard science. There is a constant, one of the fundamental constants in physics, known as Boltzmann's constant. You probably all know it very well. And the interesting thing about Boltzmann's constant is that Boltzmann didn't discover it. So why is Boltzmann's constant now named for Boltzmann? Well, the answer was that Boltzmann derived that constant from basic physics in a more fundamental way than the poor forgotten fellow who found the constant in the first place in some less fundamental way. The ethos of hard science is so strong in favor of reductionism to the more fundamental body of knowledge that you can wash the discoverer right out of history when somebody else handles his discovery in a more fundamental way. I think that is correct. I think Boltzmann's constant should be named for Boltzmann.

At any rate, in my history and Berkshire's history, Berkshire went on and on into considerable economic success while ignoring the hard form efficient markets doctrine once very popular in academic economics and ignoring the descendants of that doctrine in corporate finance, where the results became even sillier than they were in the economics. This naturally encouraged me.

Finally, with my peculiar history, I'm also bold enough to be here today, because at least when I was young I wasn't a total klutz. For one year at the Harvard Law School, I was ranked second in my group of about a thousand, and I always figured that, while there were always a lot of people much smarter than I was, I didn't have to hang back totally in the thinking game.

The Obvious Strengths of Academic Economics

Let me begin by discussing the obvious strengths of academic economics. The first obvious strength, and this is true of a lot of places that get reputations, is that it was in the right place at the right time. Two hundred years ago, aided by the growth of technology and the growth of other developments in the civilization, the real output per capita of the civilized

world started going up at about 2% per annum, compounded. And before that, for the previous thousands of years, it had gone up at a rate that hovered just a hair's breadth above zero. And, of course, economics grew up amid this huge success. Partly it helped the success, and partly it explained it. So, naturally, academic economics grew. And lately with the collapse of all the communist economies, as the free market economies or partially free market economies flourished, that added to the reputation of economics. Economics has been a very favorable place to be if you're in academia.

Economics was always more multidisciplinary than the rest of soft science. It just reached out and grabbed things as it needed to. And that tendency to just grab whatever you need from the rest of knowledge if you're an economist has reached a fairly high point in Mankiw's new textbook (Principles of Economics). I checked out that textbook. I must have been one of the few businessmen in America that bought it immediately when it came out because it had gotten such a big advance. I wanted to figure out what the guy was doing where he could get an advance that great. So this is how I happened to riffle through Mankiw's freshman textbook. And there I found laid out as principles of economics: opportunity cost is a superpower, to be used by all people who have any hope of getting the right answer. Also, incentives are superpowers.

And lastly, the tragedy of the commons model, popularized by UCSB's Garrett Hardin. Hardin caused the delightful introduction into economics – alongside Smith's beneficent invisible hand – of Hardin's wicked evil-doing invisible foot. Well, I thought that the Hardin model made economics more complete, and I knew when Hardin introduced me to his model, the Tragedy of the Commons, that it would be in the economics textbooks eventually. And, low and behold, it finally made it about 20 years later. And it's right for Mankiw to reach out into other disciplines and grab Hardin's model and anything else that works well.

Another thing that helped economics is that from the beginning it attracted the best brains in soft science. Its denizens also interacted more with the practical world than was at all common in soft science and the rest of academia, and that resulted in very creditable outcomes like the three cabinet appointments of economics PhD George Schultz and the cabinet appointment of Larry Summers. So this has been a very favored part of academia. Also, economics early on attracted some of the best writers of language in the history of the earth. You start out with Adam Smith. Adam Smith was so good a thinker, and so good a writer, that in his own time, Emmanuel Kant, then the greatest intellectual in Germany, simply announced that there was nobody in Germany to equal Adam Smith. Well Voltaire, being an even more pithy speaker than Kant, which wouldn't be that hard, immediately said, "Oh well, France doesn't have anybody who can even be compared to Adam Smith." So economics started with some very great men and great writers.

And then there have been later great writers like John Maynard Keynes, whom I quote all the time, and who has added a great amount of illumination to my life. And finally, even in the present era, if you take Paul Krugman and read his essays, you will be impressed by his fluency. I can't stand his politics; I'm on the other side. But I love this man's essays. I think Paul Krugman is one of the best essayists alive. And so economics has constantly attracted these fabulous writers. And they are so good that they have this enormous influence far outside their economic discipline, and that's very uncommon in other academic departments.

Okay, now it's time to extend criticism, instead of praise. We've recognized that economics is better than other soft-science academic departments in many ways. And one of the glories of civilization. Now it's only fair that we outline a few things that are wrong with academic economics.

What's Wrong with Economics

1) Fatal Unconnectedness, Leading To "Man With A Hammer Syndrome," Often Causing Overweighing What Can Be Counted

I think I've got eight, no nine objections, some being logical subdivisions of a big general objection. The big general objection to economics was the one early described by Alfred North Whitehead when he spoke of the fatal unconnectedness of academic disciplines, wherein each professor didn't even know the models of the other disciplines, much less try to synthesize those disciplines with his own.

I think there's a modern name for this approach that Whitehead didn't like, and that name is bonkers. This is a perfectly crazy way to behave. Yet economics, like much else in academia, is too insular.

The nature of this failure is that it creates what I always call, "man with a hammer syndrome." And that's taken from the folk saying: To the man with only a hammer, every problem looks pretty much like a nail. And that works marvelously to gum up all professions, and all departments of academia, and indeed most practical life. The only antidote for being an absolute klutz due to the presence of a man with a hammer syndrome is to have a full kit of tools. You don't have just a hammer. You've got all the tools. And you've got to have one more trick.

You've got to use those tools checklist-style because you'll miss a lot if you just hope that the right tool is going to pop up unaided whenever you need it. But if you've got a full list of tools, and go through them in your mind, checklist-style, you will find a lot of answers that you won't find any other way. So limiting this big general objection that so disturbed Alfred North Whitehead is very important, and there are mental tricks that help do the job.

Overweighing what can be counted

A special version of this "man with a hammer syndrome" is terrible, not only in economics but practically everywhere else, including business. It's really terrible in business. You've got a complex system and it spews out a lot of wonderful numbers that enable you to measure some factors. But there are other factors that are terribly important, [yet] there's no precise numbering you can put to these factors. You know they're important, but you don't have the numbers. Well practically everybody (1) overweighs the stuff that can be numbered, because it yields to the statistical techniques they're taught in academia, and (2) doesn't mix in the hard-to-measure stuff that may be more important. That is a mistake I've tried all my life to avoid, and I have no regrets for having done that.

The late, great, Thomas Hunt Morgan, who was one of greatest biologists who ever lived, when he got to Caltech, had a very interesting, extreme way of avoiding some mistakes from overcounting what could be measured, and undercounting what couldn't. At that time there were no computers and the computer substitute then available to science and engineering was the Frieden calculator, and Caltech was full of Frieden calculators. And Thomas Hunt Morgan banned the Frieden calculator from the biology department. And when they said, "What the hell are you doing, Mr. Morgan?," He said, "Well, I am like a guy who is prospecting for gold along the banks of the Sacramento River in 1849. With a little intelligence, I can reach down and pick up big nuggets of gold. And as long as I can do that, I'm not going to let any people in my department waste scarce resources in placer mining." And that's the way Thomas Hunt Morgan got through life.

I've adopted the same technique, and here I am in my 80th year. I haven't had to do any placer mining yet. And it begins to look like I'm going to get all the way through, as I'd always hoped, without doing any of that damned placer mining. Of course, if I were a physician, particularly an academic physician, I'd have to do the statistics, do the placer mining. But it's amazing what you can do in life without the placer mining if you've got a few good mental tricks and just keep ragging the problems the way Thomas Hunt Morgan did.

2) Failure To Follow The Fundamental Full Attribution Ethos of Hard Science

What's wrong with the way Mankiw does economics is that he grabs from other disciplines without attribution. He doesn't label the grabbed items as physics or biology or psychology, or game theory, or whatever they really are, fully attributing the concept to the basic

knowledge from which it came. If you don't do that, it's like running a business with a sloppy filing system. It reduces your power to be as good as you can be. Now Mankiw is so smart he does pretty well even when his technique is imperfect. He got the largest advance any textbook writer ever got.

But, nonetheless, he'd be better if he had absorbed this hard science ethos that I say has been so helpful to me.

I have names for Mankiw's approach, grabbing whatever you need without attribution. Sometimes I call it "take what you wish," and sometimes I call it "Kiplingism." And when I call it Kiplingism, I'm reminding you of Kipling's stanza of poetry, which went something like this: "When Homer smote his blooming lyre, he'd heard men sing by land and sea, and what he thought he might require, he went and took, the same as me." Well that's the way Mankiw does it. He just grabs. This is much better than not grabbing. But it is much worse than grabbing with full attribution and full discipline, using all knowledge plus extreme reductionism where feasible.

3) Physics Envy

The third weakness that I find in economics is what I call physics envy. And of course, that term has been borrowed from penis envy as described by one of the world's great idiots, Sigmund Freud. But he was very popular in his time, and the concept got a wide vogue.

Washington Post case study

One of the worst examples of what physics envy did to economics was cause adaptation and hard-form efficient market theory. And then when you logically derived consequences from this wrong theory, you would get conclusions such as: it can never be correct for any corporation to buy its own stock. Because the price by definition is totally efficient, there could never be any advantage. And they taught this theory to some partner at McKinsey when he was at some school of business that had adopted this crazy line of reasoning from economics, and the partner became a paid consultant for the Washington Post. And Washington Post stock was selling at a fifth of what an orangutan could figure was the plain value per share by just counting up the values and dividing. But he so believed what he'd been taught in graduate school that he told the Washington Post they shouldn't buy their own stock. Well, fortunately, they put Warren Buffett on the Board, and he convinced them to buy back more than half of the outstanding stock, which enriched the remaining shareholders by much more than a billion dollars. So, there was at least one instance of a place that quickly killed a wrong academic theory.

It's my view that economics could avoid a lot of this trouble that comes from physics envy. I want economics to pick up the basic ethos of hard science, the full attribution habit, but not the craving for an unattainable precision that comes from physics envy. The sort of precise reliable formula that includes Boltzmann's constant is not going to happen, by and large, in economics. Economics involves too complex a system. And the craving for that physics-style precision does little but get you in terrible trouble, like the poor fool from McKinsey.

Einstein and Sharon Stone

I think that economists would be way better off if they paid more attention to Einstein and Sharon Stone. Well, Einstein is easy because Einstein is famous for saying, "Everything should be made as simple as possible, but no more simple." Now, the saying is a tautology, but it's very useful, and some economist – it may have been Herb Stein – had a similar tautological saying that I dearly love: "If a thing can't go on forever, it will eventually stop."

Sharon Stone contributed to the subject because someone once asked her if she was bothered by penis envy. And she said, "absolutely not, I have more trouble than I can handle with what I've got." (Laughter).

When I talk about this false precision, this great hope for reliable, precise formulas, I am reminded of Arthur Laffer, who's in my political party, and who is one of the all-time horses'

asses when it comes to doing economics. His trouble is his craving for false precision, which is not an adult way of dealing with his subject matter.

The situation of people like Laffer reminds me of a rustic legislator – and this really happened in America. I don't invent these stories. Reality is always more ridiculous than what I'm going to tell you. At any rate, this rustic legislator proposed a new law in his state. He wanted to pass a law rounding Pi to an even 3.2 so it would be easier for the school children to make the computations. Well, you can say that this is too ridiculous, and it can't be fair to liken economics professors like Laffer to a rustic legislator like this. I say I'm under-criticizing the professors. At least when this rustic legislature rounded Pi to an even number, the error was relatively small. But once you try to put a lot of false precision into a complex system like economics, the errors can compound to the point where they're worse than those of the McKinsey partner when he was incompetently advising the Washington Post. So, economics should emulate physics' basic ethos, but its search for precision in physics-like formulas is almost always wrong in economics.

4) Too Much Emphasis on Macroeconomics

My fourth criticism is that there's too much emphasis on macroeconomics and not enough on microeconomics. I think this is wrong. It's like trying to master medicine without knowing anatomy and chemistry. Also, the discipline of microeconomics is a lot of fun. It helps you correctly understand macroeconomics. And it's a perfect circus to do. In contrast, I don't think macroeconomics people have all that much fun. For one thing, they are often wrong because of extreme complexity in the system they wish to understand.

Case study: Nebraska Furniture Mart's new store in Kansas City

Let me demonstrate the power of microeconomics by solving two microeconomic problems. One simple and one a little harder. The first problem is this: Berkshire Hathaway just opened a furniture and appliance store in Kansas City. At the time Berkshire opened it, the largest selling furniture and appliance store in the world was another Berkshire Hathaway store, selling \$350 million worth of goods per year. The new store in a strange city opened up selling at the rate of more than \$500 million a year. From the day it opened, the 3,200 spaces in the parking lot were full. The women had to wait outside the ladies' restroom because the architects didn't understand biology. (Laughter). It's hugely successful.

Well, I've given you the problem. Now, tell me what explains the runaway success of this new furniture and appliance store, which is outselling everything else in the world?

(Pause). Well, let me do it for you. Is this a low-priced store or a high-priced store?

(Laughter). It's not going to have a runaway success in a strange city as a high-priced store. That would take time. Number two, if it's moving \$500 million worth of furniture through it, it's one hell of a big store, furniture being as bulky as it is. And what does a big store do? It provides a big selection. So what could this possibly be except a low-priced store with a big selection?

But, you may wonder, why wasn't it done before, preventing its being done first now?

Again, the answer just pops into your head: it costs a fortune to open a store this big. So, nobody's done it before. So, you quickly know the answer. With a few basic concepts, these microeconomic problems that seem hard can be solved much as you put a hot knife through butter. I like such easy ways of thought that are very remunerative. And I suggest that you people should also learn to do microeconomics better

Case study: Les Schwab Tires

Now I'll give you a harder problem. There's a tire store chain in the Northwest, which has slowly succeeded over 50 years, the Les Schwab tire store chain. It just ground ahead. It started competing with the stores that were owned by the big tire companies that made all the tires, the Goodyears and so forth. And, of course, the manufacturers favored their own stores. Their "tied stores" had a big cost advantage. Later, Les Schwab rose in competition with the huge price discounters like Costco and Sam's Club and before that Sears

Roebuck and so forth. And yet here is Schwab now, with hundreds of millions of dollars in sales. And here's Les Schwab in his 80s, with no education, having done the whole thing. How did he do it? (Pause). I don't see a whole lot of people looking like a light bulb has come on. Well, let's think about it with some microeconomic fluency.

Is there some wave that Schwab could have caught? The minute you ask the question, the answer pops in. The Japanese had a zero position in tires and they got big. So this guy must have ridden that wave some in the early times. Then the slow following success has to have some other causes. And what probably happened here, obviously, is this guy did one hell of a lot of things right. And among the things that he must have done right is he must have harnessed what Mankiw calls the superpower of incentives. He must have a very clever incentive structure driving his people. And a clever personnel selection system, etc. And he must be pretty good at advertising. Which he is. He's an artist. So, he had to get a wave in the Japanese tire invasion, the Japanese being as successful as they were. And then a talented fanatic had to get a hell of a lot of things right, and keep them right with clever systems. Again, not that hard of an answer. But what else would be a likely cause of the peculiar success?

We hire business school graduates and they're no better at these problems than you were. Maybe that's the reason we hire so few of them.

Causes of problem-solving success

Well, how did I solve those problems? Obviously, I was using a simple search engine in my mind to go through checklist-style, and I was using some rough algorithms that work pretty well in a great many complex systems, and those algorithms run something like this:

Extreme success is likely to be caused by some combination of the following factors:

A) Extreme maximization or minimization of one or two variables. Example, Costco or our furniture and appliance store.

B) Adding success factors so that a bigger combination drives success, often in a non-linear fashion, as one is reminded by the concept of breakpoint and the concept of critical mass in physics. Often results are not linear. You get a little bit more mass, and you get a lollapalooza result. And of course, I've been searching for lollapalooza results all my life, so I'm very interested in models that explain their occurrence.

C) An extreme of good performance over many factors. Example, Toyota or Les Schwab.

D) Catching and riding some sort of big wave. For example, Oracle. By the way, I put down Oracle before I knew that the Oracle CFO was a big part of the proceedings here today.

Generally, I recommend and use in problem-solving cut-to-the quick algorithms, and I find you have to use them both forward and backward. Let me give you an example. I irritate my family by giving them little puzzles, and one of the puzzles that I gave my family not very long ago was when I said, "There's an activity in America, with one-on-one contests, and a national championship. The same person won the championship on two occasions about 65 years apart." "Now," I said, "name the activity," (Pause). Again, I don't see a lot of light bulbs going on. And in my family, not a lot of light bulbs were flashing. But I have a physicist son who has been trained more in the type of thinking I like. And he immediately got the right answer, and here's the way he reasoned:

It can't be anything requiring a lot of hand-eye coordination. Nobody 85 years of age is going to win a national billiards tournament, much less a national tennis tournament. It just can't be. Then he figured it couldn't be chess, which this physicist plays very well, because it's too hard. The complexity of the system, the stamina required are too great. But that led into checkers. And he thought, "Ah ha! There's a game where vast experience might guide you to be the best even though you're 85 years of age."

And sure enough, that was the right answer.

Anyway, I recommend that sort of mental trickery to all of you, flipping one's thinking both backward and forward. And I recommend that academic economics get better at very small-scale microeconomics as demonstrated here.

5) Too Little Synthesis in Economics

My fifth criticism is there is too little synthesis in economics. Not only with matters outside traditional economics, but also within economics. I have posed at two different business schools the following problem. I say, "You have studied supply and demand curves. You have learned that when you raise the price, ordinarily the volume you can sell goes down, and when you reduce the price, the volume you can sell goes up. Is that right? That's what you've learned?" They all nod yes. And I say, "Now tell me several instances when, if you want the physical volume to go up, the correct answer is to increase the price?" And there's this long and ghastly pause. And finally, in each of the two business schools in which I've tried this, maybe one person in fifty could name one instance. They come up with the idea that occasionally a higher price acts as a rough indicator of quality and thereby increases sales volumes.

This happened in the case of my friend Bill Ballhaus. When he was head of Beckman Instruments it produced some complicated product where if it failed it caused enormous damage to the purchaser. It wasn't a pump at the bottom of an oil well, but that's a good mental example. And he realized that the reason this thing was selling so poorly, even though it was better than anybody else's product, was because it was priced lower. It made people think it was a low quality gizmo. So he raised the price by 20% or so and the volume went way up. But only one in fifty can come up with this sole instance in a modern business school – one of the business schools being Stanford, which is hard to get into. And nobody has yet come up with the main answer that I like. Suppose you raise that price, and use the extra money to bribe the other guy's purchasing agent? (Laughter). Is that going to work? And are there functional equivalents in economics – microeconomics – of raising the price and using the extra sales proceeds to drive sales higher? And of course there are a zillion, once you've made that mental jump. It's so simple.

One of the most extreme examples is in the investment management field. Suppose you're the manager of a mutual fund, and you want to sell more. People commonly come to the following answer: You raise the commissions, which of course reduces the number of units of real investments delivered to the ultimate buyer, so you're increasing the price per unit of real investment that you're selling the ultimate customer. And you're using that extra commission to bribe the customer's purchasing agent. You're bribing the broker to betray his client and put the client's money into the high-commission product. This has worked to produce at least a trillion dollars of mutual fund sales.

This tactic is not an attractive part of human nature, and I want to tell you that I pretty completely avoided it in my life. I don't think it's necessary to spend your life selling what you would never buy. Even though it's legal, I don't think it's a good idea. But you shouldn't accept all my notions because you'll risk becoming unemployable. You shouldn't take my notions unless you're willing to risk being unemployable by all but a few.

I think my experience with my simple question is an example of how little synthesis people get, even in advanced academic settings, considering economic questions. Obvious questions, with such obvious answers. Yet people take four courses in economics, go to business school, have all these IQ points and write all these essays, but they can't synthesize worth a damn. This failure is not because the professors know all this stuff and they're deliberately withholding it from the students. This failure happens because the professors aren't all that good at this kind of synthesis. They were trained in a different way. I can't remember if it was Keynes or Galbraith who said that economics professors are most economical with ideas. They make a few they learned in graduate school last a lifetime. (Laughter).

The second problem with synthesis

The second interesting problem with synthesis involves two of the most famous examples in the economics. Number one is Ricardo's principle of comparative advantage in trade, and the other is Adam Smith's pin factory. And both of these, of course, work to vastly

increase economic output per person, and they're similar in that each somehow directs functions into the hands of people who are very good at doing the functions. Yet they're radically different examples in that one of them is the ultimate example of central planning, the pin factory, where the whole system was planned by somebody, while the other example, Ricardo's, happens automatically as a natural consequence of trade.

And, of course, once you get into the joys of synthesis, you immediately think. "Do these things interact?" Of course they interact. Beautifully. And that's one of the causes of the power of a modern economic system. I saw an example of that kind of interaction years ago. Berkshire had this former savings and loan company, and it had made this loan on a hotel right opposite the Hollywood Park Racetrack. In due time the neighborhood changed and it was full of gangs, pimps, and dope dealers. They tore copper pipe out of the wall for dope fixes, and there were people hanging around the hotel with guns, and nobody would come. We foreclosed on it two or three times, and the loan value went down to nothing. We seemed to have an insolvable economic problem — a microeconomic problem.

Now we could have gone to McKinsey, or maybe a bunch of professors from Harvard, and we would have gotten a report about 10 inches thick about the ways we could approach this failing hotel in this terrible neighborhood. But instead, we put a sign on the property that said: "For sale or rent." And in came, in response to that sign, a man who said, "I'll spend \$200,000 fixing up your hotel, and buy it at a high price on credit, if you can get zoning so I can turn the parking lot into a putting green." "You've got to have a parking lot in a hotel," we said. "What do you have in mind?" He said. "No, my business is flying seniors in from Florida, putting them near the airport, and then letting them go out to Disneyland and various places by bus and coming back. And I don't care how bad the neighborhood is going to be because my people are selfcontained behind walls. All they have to do is get on the bus in the morning and come home in the evening, and they don't need a parking lot; they need a putting green." So we made the deal with the guy. The whole thing worked beautifully, and the loan got paid off, and it all worked out.

Obviously that's an interaction of Ricardo and the pin factory examples. The odd system that this guy had designed to amuse seniors was pure pin factory, and finding the guy with this system was pure Ricardo. So these things are interacting.

Well, I've taken you part way through the synthesis. It gets harder when you want to figure out how much activity should be within private firms, and how much should be within the government, and what are the factors that determine which functions are where, and why do the failures occur, and so on and so on.

It's my opinion that anybody with a high IQ who graduated in economics ought to be able to sit down and write a ten-page synthesis of all these ideas that's quite persuasive. And I would bet a lot of money that I could give this test in practically every economics department in the country, and get a perfectly lousy bunch of synthesis. They'd give me Ronald Coase. They'd talk about transaction costs. They'd click off a little something that their professors gave them and spit it back. But in terms of really understanding how it all fits together, I would confidently predict that most people couldn't do it very well.

By the way, if any of you want to try and do this, go ahead. I think you'll find it hard. In this connection, one of the interesting things that I want to mention is that Max Planck, the great Nobel laureate who found Planck's Constant, tried once to do economics. He gave it up. Now why did Max Planck, one of the smartest people who ever lived, give up economics? The answer is, he said, "It's too hard. The best solution you can get is messy and uncertain." It didn't satisfy Planck's craving for order, and so he gave it up. And if Max Planck early on realized he was never going to get perfect order, I will confidently predict that all of the rest of you are going to have exactly the same result.

By the way there's a famous story about Max Planck which is apocryphal: After he won his prize, he was invited to lecture everywhere, and he had this chauffeur that drove him around to give public lectures all through Germany. And the chauffeur memorized the

lecture, and so one day he said, "Gee Professor Planck, why don't you let me try it as we switch places?" And so he got up and gave the lecture. At the end of it some physicist stood up and posed a question of extreme difficulty. But the chauffeur was up to it. "Well," he said, "I'm surprised that a citizen of an advanced city like Munich is asking so elementary a question, so I'm going to ask my chauffeur to respond." (Laughter).

6) Extreme and Counterproductive Psychological Ignorance

All right, I'm down to the sixth main defect, and this is a subdivision of the lack of adequate multidisciplinary: Extreme and counterproductive psychological ignorance in economics. Here I want to give you a very simple problem. I specialize in simple problems. You own a small casino in Las Vegas. It has fifty standard slot machines. Identical in appearance, they're identical in function. They have exactly the same payout ratios. The things that cause the payouts are exactly the same. They occur in the same percentages. But there's one machine in this group of slot machines that, no matter where you put it among the fifty, in fairly short order, when you go to the machines at the end of the day, there will be 25% more winnings from this one machine than from any other machine. Now surely I'm not going to have a failure here. What is different about that heavy winning machine? (Silence) Can anybody do it?

Male: More people play it.

Charles Munger: No, no, I want to know why more people play it. What's different about that machine is people have used modern electronics to give a higher ratio of near misses. That machine is going bar, bar, lemon. Bar, bar, grapefruit, way more often than normal machines, and that will cause heavier play. How do you get an answer like that? Easy. Obviously, there's a psychological cause: That machine is doing something to trigger some basic psychological response.

If you know the psychological factors, if you've got them on a checklist in your head, you just run down the factors, and, boom!, you get to one that must explain this occurrence. There isn't any other way to do it effectively. These answers are not going to come to people who don't learn these mental tricks. If you want to go through life like a one-legged man in an ass-kicking contest, why be my guest. But if you want to succeed, like a strong man with two legs, you have to pick up these tricks, including doing economics while knowing psychology.

In this vein, I next want to mention a strange Latin American case of a dysfunctional economy that got fixed. In this little subdivision of Latin America, a culture had arisen wherein everybody stole everything. They embezzled from the company, they stole everything that was loose in the community. And of course, the economy came practically to a halt. And this thing got fixed. Now where did I read about this case? I'll give you a hint. It wasn't in the annals of economics. I found this case in the annals of psychology. Clever people went down and used a bunch of psychological tricks. And they fixed it.

Well, I think there's no excuse if you're an economist, when there are wonderful cases like that of the dysfunctional economy becoming fixed, and these simple tricks that solve so many problems, and you don't know how to do the fixes and understand the problems. Why be so ignorant about psychology that you don't even know psychology's tricks that will fix your own dysfunctional economic systems?

Here I want to give you an extreme injunction. This is even tougher than the fundamental organizing ethos of hard science. This has been attributed to Samuel Johnson. He said in substance that if an academic maintains in place an ignorance that can be easily removed with a little work, the conduct of the academic amounts to treachery. That was his word, "treachery." You can see why I love this stuff. He says you have a duty if you're an academic to be as little of a klutz as you can possibly be, and therefore you have got to keep grinding out of your system as much removable ignorance as you can remove.

7) Too Little Attention to Second and Higher Order Effects

On to the next one the seventh defect: Too little attention in economics to second order and even higher order effects. This defect is quite understandable, because the consequences have consequences, and the consequences of the consequences have consequences, and so on. It gets very complicated. When I was a meteorologist I found this stuff very irritating. And economics makes meteorology look like a tea party.

Mispredicting Medicare costs

Extreme economic ignorance was displayed when various experts, including Ph D. economists, forecast the cost of the original Medicare law. They did simple extrapolations of past costs. Well the cost forecast was off by a factor of more than 1000%. The cost they projected was less than 10% of the cost that happened. Once they put in place all these new incentives, the behavior changed in response to the incentives, and the numbers became quite different from their projection. And medicine invented new and expensive remedies, as it was sure to do. How could a great group of experts make such a silly forecast? Answer: They over simplified to get easy figures, like the rube rounding Pi to 3.2! They chose not to consider effects of effects on effects, and so on.

Investing in textile looms

One good thing about this common form of misthinking from the viewpoint of academia, is that business people are even more foolish about microeconomics. The business version of the Medicare-type insanity is when you own a textile plant and a guy comes in and says, "Oh, isn't this wonderful? They invented a new loom. It'll pay for itself in three years at current prices because it adds so much efficiency to the production of textiles." And you keep buying these looms for 20 years, and their equivalent, and you keep making 4% on capital, you never go anywhere. And the answer is, it wasn't that technology didn't work, it's that the laws of economics caused the benefit from the new looms to go to the people that bought the textiles, not the guy that owned the textile plant. How could anybody not know that if he'd taken freshmen economics or been through business school? I think the schools are doing a lousy job. Otherwise such insanities wouldn't happen so often. Usually, I don't use formal projections. I don't let people do them for me because I don't like throwing up on the desk (laughter), but I see them made in a very foolish way all the time, and many people believe in them, no matter how foolish they are. It's an effective sales technique in America to put a foolish projection on a desk.

And if you're an investment banker, it's an art form. I don't read their projections either. Once Warren and I bought a company and the seller had a big study done by an investment banker, it was about this thick. We just turned it over as if it were a diseased carcass. He said, "We paid \$2 million for that." I said, "We don't use them. Never look at them."

Workman's comp madness

Anyway, as the Medicare example showed, all human systems are gamed, for reasons rooted deeply in psychology, and great skill is displayed in the gaming because game theory has so much potential. That's what's wrong with the workman's comp system in California. Gaming has been raised to an art form. In the course of gaming the system, people learn to be crooked. Is this good for civilization? Is it good for economic performance? Hell no. The people who design easily-gameable systems belong in the lowest circle of hell.

I've got a friend whose family controls about 8% of the truck trailer market. He just closed his last factory in California and he had one in Texas that was even worse. The workman's comp cost in his Texas plant got to be about 30% of payroll. Well, there's no such profit in making truck trailers. He closed his plant and moved it to Ogden, Utah, where a bunch of believing Mormons are raising big families and don't game the workman's comp system. The workman's comp expense is 2% of payroll.

Are the Latinos who were peopling his plant in Texas intrinsically dishonest or bad compared to the Mormons? No. It's just the incentive structure that so rewards all this

fraud is put in place by these ignorant legislatures, many members of which have been to law school, and they just don't think about what terrible things they're doing to the civilization because they don't take into account the second order effects and the third order effects in lying and cheating. So, this happens everywhere, and when economics is full of it, it is just like the rest of life.

Niederhoffer the curriculum

There was a wonderful example of gaming a human system in the career of Victor Niederhoffer in the Economics Department of Harvard. Victor Niederhoffer was the son of a police lieutenant, and he needed to get A's at Harvard. But he didn't want to do any serious work at Harvard, because what he really liked doing was, one, playing world-class checkers; two, gambling in high-stakes card games, at which he was very good, all hours of the day and night; three, being the squash champion of the United States, which he was for years; and, four, being about as good a tennis player as a part-time tennis player could be.

This did not leave much time for getting A's at Harvard so he went into the Economics Department. You'd think he would have chosen French poetry. But remember, this was a guy who could play championship checkers. He thought he was up to outsmarting the Harvard Economics Department. And he was. He noticed that the graduate students did most of the boring work that would otherwise go to the professors, and he noticed that because it was so hard to get to be a graduate student at Harvard, they were all very brilliant and organized and hard working, as well as much needed by grateful professors. And therefore, by custom, and as would be predicted from the psychological force called reciprocity tendency, in a really advanced graduate course, the professors always gave an A. So Victor Niederhoffer signed up for nothing but the most advanced graduate courses in the Harvard Economics Department, and of course, he got A, after A, after A, after A, and was hardly ever near a class. And for a while, some people at Harvard may have thought it had a new prodigy on its hands. That's a ridiculous story, but the scheme will work still. And Niederhoffer is famous: they call his style "Niederhoffer the curriculum." (Laughter). This shows how all-human systems are gamed. Another example of not thinking through the consequences of the consequences is the standard reaction in economics to Ricardo's law of comparative advantage giving benefit on both sides of trade. Ricardo came up with a wonderful, non-obvious explanation that was so powerful that people were charmed with it, and they still are, because it's a very useful idea. Everybody in economics understands that comparative advantage is a big deal, when one considers first order advantages in trade from the Ricardo effect. But suppose you've got a very talented ethnic group, like the Chinese, and they're very poor and backward, and you're an advanced nation, and you create free trade with China, and it goes on for a long time.

Now let's follow with second and third order consequences: You are more prosperous than you would have been if you hadn't traded with China in terms of average well-being in the United States, right? Ricardo proved it. But which nation is going to be growing faster in economic terms? It's obviously China. They're absorbing all the modern technology of the world through this great facilitator in free trade, and, like the Asian Tigers have proved, they will get ahead fast. Look at Hong Kong. Look at Taiwan. Look at early Japan. So, you start in a place where you've got a weak nation of backward peasants, a billion and a quarter of them, and in the end they're going to be a much bigger, stronger nation than you are, maybe even having more and better atomic bombs. Well, Ricardo did not prove that that's a wonderful outcome for the former leading nation. He didn't try to determine second order and higher order effects.

If you try and talk like this to an economics professor, and I've done this three times, they shrink in horror and offense because they don't like this kind of talk. It really gums up this nice discipline of theirs, which is so much simpler when you ignore second and third order consequences.

The best answer I ever got on that subject – in three tries – was from George Schultz. He said, “Charlie, the way I figure it is if we stop trading with China, the other advanced nations will do it anyway, and we wouldn’t stop the ascent of China compared to us, and we’d lose the Ricardodiagnosed advantages of trade.” Which is obviously correct. And I said, “Well George, you’ve just invented a new form of the tragedy of the commons. You’re locked in this system and you can’t fix it. You’re going to go to a tragic hell in a handbasket, if going to hell involves being once the great leader of the world and finally going to the shallows in terms of leadership.” And he said, “Charlie, I do not want to think about this.” I think he’s wise. He’s even older than I am, and maybe I should learn from him.

8) Not Enough Attention to the Concept of Febezzlement

Okay, I’m now down to my eighth objection: Too little attention within economics to the simplest and most fundamental principle of algebra. Now this sounds outrageous, that economics doesn’t do algebra, right? Well, I want to try an example – I may be wrong on this. I’m old and I’m iconoclastic – but I throw it out anyway. I say that economics doesn’t pay enough attention to the concept of febezzlement. And that I derive from Galbraith’s idea. Galbraith’s idea was that, if you have an undisclosed embezzlement, it has a wonderful Keynesian stimulating effect on the economy because the guy who’s been embezzled thinks he is as rich as he always was and spends accordingly, and the guy that had stolen the money gets all this new purchasing power. I think that’s correct analysis on Galbraith’s part. The trouble with his notion is that he’s described a minor phenomenon. Because when the embezzlement is discovered, as it almost surely will be, the effect will quickly reverse. So the effect quickly cancels out.

But suppose you paid a lot of attention to algebra, which I guess Galbraith didn’t, and you think, “Well, the fundamental principle of algebra is, ‘If A is equal to B and B is equal to C, then A is equal to C.’” You’ve then got a fundamental principle that demands that you look for functional equivalents, all you can find. So suppose you ask the question, “Is there such a thing in economics as a febezzlement?” By the way, Galbraith invented the word “bezzle” to describe the amount of undisclosed embezzlement, so I invented the word “febezzlement”: the functional equivalent of embezzlement.

This happened after I asked the question “Is there a functional equivalent of embezzlement?” I came up with a lot of wonderful affirmative answers. Some were in investment management. After all I’m near investment management. I considered the billions of dollars totally wasted in the course of investing common stock portfolios for American owners. As long as the market keeps going up, the guy who’s wasting all this money doesn’t feel it, because he’s looking at these steadily rising values. And to the guy who is getting the money for investment advice, the money looks like well earned income, when he’s really selling detriment for money, surely the functional equivalent of undisclosed embezzlement. You can see why I don’t get invited to many lectures.

So I say, if you look in the economy for febezzlement, the functional equivalent of embezzlement, you’ll find some enormously powerful factors. They create some “wealth effect” that is on steroids, compared to the old “wealth effect.” But practically nobody thinks as I do, and I quitclaim my idea to any hungry graduate student who has independent means, which he will need before his thesis topic is approved.

9) Not Enough Attention to Virtue and Vice Effects

Okay, my ninth objection: Not enough attention to virtue and vice effects in economics. It has been plain to me since early life that there are enormous virtue effects in economics, and also enormous vice effects. But economists get very uncomfortable when you talk about virtue and vice. It doesn’t lend itself to a lot of columns of numbers. But I would argue that there are big virtue effects in economics. I would say that the spreading of double-entry bookkeeping by the Monk, Fra Luca de Pacioli, was a big virtue effect in economics. It made business more controllable, and it made it more honest. Then the cash

register. The cash register did more for human morality than the congregational church. It was a really powerful phenomenon to make an economic system work better, just as, in reverse, a system that can be easily defrauded ruins a civilization. A system that's very hard to defraud, like a cash register, helps the economic performance of a civilization by reducing vice, but very few people within economics talk about it in those terms.

Religion

I'll go further: I say economic systems work better when there's an extreme reliability ethos. And the traditional way to get a reliability ethos, at least in past generations in America, was through religion. The religions instilled guilt. We have a charming Irish Catholic priest in our neighborhood and he loves to say, "Those old Jews may have invented guilt, but we perfected it." (Laughter). And this guilt, derived from religion, has been a huge driver of a reliability ethos, which has been very helpful to economic outcomes for man.

Pay for directors and judges

Many bad effects from vice are clear. You've got the crazy booms and crooked promotions – all you have to do is read the paper over the last six months. There's enough vice to make us all choke. And, by the way, everybody's angry about unfair compensation at the top of American corporations, and people should be. We now face various crazy nostrums invented by lawyers which won't give us a fix for unfair compensation, yet a good partial solution is obvious: If directors were significant shareholders who got a pay of zero, you'd be amazed what would happen to unfair compensation of corporate executives as we dampened effects from reciprocity tendency.

A roughly similar equivalent of this no-pay system has been tried in a strange place. In England, the lower criminal courts which can send you to prison for a year or fine you substantially, are staffed by lay magistrates. You've got three judges sitting up there, and they all get a pay of zero. Their expenses are reimbursed, but not too liberally. And they work about 40 half-days a year, as volunteers. It's worked beautifully for about 700 years. Able and honest people compete to become magistrates, to perform the duty and get the significance, but no pay.

This is the system Benjamin Franklin, near the end of his life, wanted for U.S. government. He didn't want the high executives of government to be paid, but to be like himself or the entirely unpaid, well-off ministers and rulers of the Mormon Church. And when I see what's happened in California, I'm not sure he wasn't right. At any rate, no one now drifts in Franklin's direction. For one thing, professors – and most of them need money – get appointed directors.

Not a vice that some systems are deliberately made unfair. It is not always recognized that, to function best, morality should sometimes appear unfair, like most worldly outcomes. The craving for perfect fairness causes a lot of terrible problems in system function. Some systems should be made deliberately unfair to individuals because they'll be fairer on average for all of us. I frequently cite the example of having your career over, in the Navy, if your ship goes aground, even if it wasn't your fault. I say the lack of justice for the one guy that wasn't at fault is way more than made up by a greater justice for everybody when every captain of a ship always sweats blood to make sure the ship doesn't go aground. Tolerating a little unfairness to some to get greater fairness for all is a model I recommend to all of you. But again, I wouldn't put it in your assigned college work if you want to be graded well, particularly in a modern law school wherein there is usually an over-love of fairness-seeking process.

Contributions of vice to bubbles

There are, of course, enormous vice effects in economics. You have these bubbles with so much fraud and folly. The aftermath is frequently very unpleasant, and we've had some of that lately. One of the first big bubbles, of course, was the huge and horrible South Sea bubble in England.

And the aftermath was interesting. Many of you probably don't remember what happened after the South Sea Bubble, which caused an enormous financial contraction, and a lot of pain. They banned publicly traded stock in England for decades. Parliament passed a law that said you can have a partnership with a few partners, but you can't have publicly traded stock. And, by the way, England continued to grow without publicly traded stock. The people who are in the business of prospering because there's a lot of stock being traded in casino-like frenzy wouldn't like this example if they studied it enough. It didn't ruin England to have a long period when they didn't have publicly traded shares. Just as in real estate. We had all the shopping centers and auto dealerships, and so on, we needed for years when we didn't have publicly traded real estate shares. It's a myth that once you've got some capital market, economic considerations demand that it has to be as fast and efficient as a casino. It doesn't.

Paradoxical good contributions from vice; the irremovability of paradox

Another interesting problem is raised by vice effects involving envy. Envy wisely got a very strong condemnation in the laws of Moses. You remember how they laid it on with a trowel: You couldn't covet thy neighbor's ass, you couldn't covet thy neighbor's servant girl, you couldn't covet...—Those old Jews knew how envious people are and how much trouble it caused. They really laid it on hard, and they were right. But Mandeville, remember his fable of bees? He demonstrated convincingly – to me, anyway – that envy was a great driver of proclivity to spend.

And so here's this terrible vice, which is forbidden in the Ten Commandments, and here it's driving all these favorable results in economics. There's some paradox in economics that nobody's going to get out.

When I was young, everybody was excited by Godel who came up with proof that you couldn't have a mathematical system without a lot of irritating incompleteness in it. Well, since then my betters tell me that they've come up with more irremovable defects in mathematics and have decided that you're never going to get mathematics without some paradox in it. No matter how hard you work, you're going to have to live with some paradox if you're a mathematician.

Well, if the mathematicians can't get the paradox out of their system when they're creating it themselves, the poor economists are never going to get rid of paradoxes, nor are any of the rest of us. It doesn't matter. Life is interesting with some paradoxes. When I run into a paradox I think either I'm a total horse's ass to have gotten to this point, or I'm fruitfully near the edge of my discipline. It adds excitement to life to wonder which it is.

Conclusion

Clinging to failed ideas – a horror story

As I conclude, I want to tell one more story demonstrating how awful it is to get a wrong idea from a limited repertoire and just stick to it. And this is the story of Hyman Liebowitz who came to America from the old country. In the new country, as in the old, he tried to make his way in the family trade, which was manufacturing nails. And he struggled and he struggled, and finally, his little nail business got to vast prosperity, and his wife said to him, "You are old, Hyman, it's time to go to Florida and turn the business over to our son."

So down he went to Florida, turning his business over to the son, but he got weekly financial reports. And he hadn't been in Florida very long before they turned sharply negative. In fact, they were terrible. So he got on an airplane and he went back to New Jersey, where the factory was. As he left the airport on the way to the factory he saw this enormous outdoor advertising sign lighted up. And there was Jesus, spread out on the cross. And under it was a big legend, "They Used Liebowitz's Nails." So he stormed into the factory and said, "You dumb son! What do you think you're doing? It took me 50 years to create this business!" "Papa," he said, "trust me. I will fix it."

So back he went to Florida, and while he was in Florida he got more reports, and the results kept getting worse. So he got on the airplane again. Left the airport, drove by the

sign, looked up at this big lighted sign, and now there's a vacant cross. And, low and behold, Jesus is crumpled on the ground under the cross, and the sign said, "They Didn't Use Liebowitz's Nails." (Laughter). Well, you can laugh at that. It is ridiculous but it's no more ridiculous than the way a lot of people cling to failed ideas.

Keynes said "It's not bringing in the new ideas that's so hard. It's getting rid of the old ones." And Einstein said it better, attributing his mental success to "curiosity, concentration, perseverance, and self-criticism." By self-criticism, he meant becoming good at destroying your own best-loved and hardest-won ideas. If you can get really good at destroying your own wrong ideas, that is a great gift.

Repeating the big lesson

Well, it's time to repeat the big lesson in this little talk. What I've urged is the use of a bigger multidisciplinary bag of tricks, mastered to fluency, to help economics and everything else. And I also urged that people not be discouraged by irremovable complexity and paradox. It just adds more fun to the problems. My inspiration again is Keynes: Better roughly right than precisely wrong.

And so I end by repeating what I said once before on a similar occasion. If you skillfully follow the multidisciplinary path, you will never wish to come back. It would be like cutting off your hands.

Well, that's the end. I'll take questions as long as people can endure me.

35. Karl Popper: The Line Between Science and Pseudoscience

It's not immediately clear to the layman what the essential difference is between science and something masquerading as science: pseudoscience. The distinction between the two is at the core of what comprises human knowledge: How do we actually know something to be true?

Sir Karl Popper (1902-1994), the scientific philosopher, was interested in the same problem. How do we actually define the scientific process? How do we know which theories can be said to be truly explanatory?

He began addressing it in a lecture, which is printed in the book Conjectures and Refutations: The Growth of Scientific Knowledge:

When I received the list of participants in this course and realized that I had been asked to speak to philosophical colleagues I thought, after some hesitation and consultation, that you would probably prefer me to speak about those problems which interest me most, and about those developments with which I am most intimately acquainted. I therefore decided to do what I have never done before: to give you a report on my own work in the philosophy of science, since the autumn of 1919 when I first began to grapple with the problem, 'When should a theory be ranked as scientific?' or 'Is there a criterion for the scientific character or status of a theory?'

Popper saw a problem with the number of theories he considered *non-scientific*.

Theories that, on their surface, seemed to have a lot in common with good, hard, rigorous science. But the question of how we decide which theories are compatible with the scientific method, and those which are not, was harder than it seemed.

What's Scientific?

It is most common to say that science is done by collecting observations and grinding out theories from them. Charles Darwin said, after working long and hard on the problem (see the work of thinking):

My mind seems to have become a kind of machine for grinding general laws out of large collections of facts.

This is a popularly accepted notion. We observe, observe, and observe, and we look for theories to best *explain* the mass of facts. (Although even this is not really true: Popper points out that we must start with some *a priori* knowledge to be able to generate new knowledge. Observation is always done with some hypotheses in mind — we can't understand the world from a totally blank slate.)

The problem, as Popper saw it, is that some bodies of knowledge, more properly named pseudoscience, would be considered scientific if the "Observe & Deduce" operating definition were left alone. For example, a believing astrologist can ably provide you with "evidence" that their theories are sound. The biographical information of a great many people can be explained this way, they'd say.

The astrologist would tell you, for example, about how "Leos" seek to be the centre of attention; ambitious, strong, seeking the limelight. As proof, they might follow up with a host of real-life Leos: World-leaders, celebrities, politicians, and so on. In some sense, the theory would hold up. The observations could be explained by the theory, which is how science works, right?

Popper lived during a time when psychoanalytic theories were all the rage at just the same time Einstein was laying out a new foundation for the physical sciences with the concept of relativity. What made Popper uncomfortable were *comparisons between the two*. Why did he feel so uneasy putting Marxist theories and Freudian psychology in the same category of knowledge as Einstein's Relativity? Did all three not have vast explanatory power in the world? Each theory's proponents certainly believed so, but Popper was not satisfied.

It was during the summer of 1919 that I began to feel more and more dissatisfied with these three theories—the Marxist theory of history, psychoanalysis, and individual psychology; and I began to feel dubious about their claims to scientific status. My problem perhaps first took the simple form, ‘What is wrong with Marxism, psycho-analysis, and individual psychology? Why are they so different from physical theories, from Newton’s theory, and especially from the theory of relativity?’

I found that those of my friends who were admirers of Marx, Freud, and Adler, were impressed by a number of points common to these theories, and especially by their apparent explanatory power. These theories appeared to be able to explain practically everything that happened within the fields to which they referred. The study of any of them seemed to have the effect of an intellectual conversion or revelation, opening your eyes to a new truth hidden from those not yet initiated. Once your eyes were thus opened you saw confirming instances everywhere: the world was full of verifications of the theory. Whatever happened always confirmed it. Thus its truth appeared manifest; and unbelievers were clearly people who did not want to see the manifest truth; who refused to see it, either because it was against their class interest, or because of their repressions which were still ‘un-analysed’ and crying aloud for treatment.

The Importance of Falsifiability

Here was the salient problem: The proponents of these new sciences saw validations and verifications of their theories everywhere. If you were having trouble as an adult, it could *always* be explained by something your mother or father had done to you when you were young, some repressed something-or-other that hadn’t been analyzed and solved. They were confirmation bias machines.

What was the missing element? Popper had figured it out before long: The non-scientific theories could not be *falsified*. They were not *testable* in a legitimate way. There was no possible objection that could be raised which would show the theory to be wrong.

In a true science, the following statement can be easily made: “If x happens, it would show demonstrably that theory y is not true.” We can then design an experiment, a physical one or sometimes a simple thought experiment, to figure out if x actually does happen. It’s the opposite of looking for verification; you must try to show the theory is *incorrect*, and if you fail to do so, thereby *strengthen* it.

Pseudosciences cannot and do not do this—they are not strong enough to hold up. As an example, Popper discussed Freud’s theories of the mind in relation to Alfred Adler’s so-called “individual psychology,” which was popular at the time:

I may illustrate this by two very different examples of human behaviour: that of a man who pushes a child into the water with the intention of drowning it; and that of a man who sacrifices his life in an attempt to save the child. Each of these two cases can be explained with equal ease in Freudian and in Adlerian terms. According to Freud the first man suffered from repression (say, of some component of his Oedipus complex), while the second man had achieved sublimation. According to Adler the first man suffered from feelings of inferiority (producing perhaps the need to prove to himself that he dared to commit some crime), and so did the second man (whose need was to prove to himself that he dared to rescue the child). I could not think of any human behaviour which could not be interpreted in terms of either theory. It was precisely this fact—that they always fitted, that they were always confirmed—which in the eyes of their admirers constituted the strongest argument in favour of these theories. It began to dawn on me that this apparent strength was in fact their weakness.

Popper contrasted these theories against Relativity, which made specific, verifiable predictions, giving the conditions under which the predictions *could be shown false*. It turned out that Einstein’s predictions came to be true when tested, thus verifying the theory through attempts to falsify it. But the essential nature of the theory gave grounds under which it could have been wrong. To this day, physicists seek to figure out where

Relativity *breaks down* in order to come to a more fundamental understanding of physical reality. And while the theory may eventually be proven incomplete or a special case of a more general phenomenon, it has still made accurate, testable predictions that have led to practical breakthroughs.

Thus, in Popper's words, science requires testability: *"If observation shows that the predicted effect is definitely absent, then the theory is simply refuted."* This means a good theory must have an element of risk to it. It must be able to be proven wrong under stated conditions.

Popper's Essential Conclusions

From there, Popper laid out his essential conclusions, which are useful to any thinker trying to figure out if a theory they hold dear is something that can be put in the scientific realm:

1. *It is easy to obtain confirmations, or verifications, for nearly every theory—if we look for confirmations.*
2. *Confirmations should count only if they are the result of risky predictions; that is to say, if, unenlightened by the theory in question, we should have expected an event which was incompatible with the theory—an event which would have refuted the theory.*
3. *Every 'good' scientific theory is a prohibition: it forbids certain things to happen. The more a theory forbids, the better it is.*
4. *A theory which is not refutable by any conceivable event is nonscientific. Irrefutability is not a virtue of a theory (as people often think) but a vice.*
5. *Every genuine test of a theory is an attempt to falsify it, or to refute it. Testability is falsifiability; but there are degrees of testability: some theories are more testable, more exposed to refutation, than others; they take, as it were, greater risks.*
6. *Confirming evidence should not count except when it is the result of a genuine test of the theory; and this means that it can be presented as a serious but unsuccessful attempt to falsify the theory. (I now speak in such cases of 'corroborating evidence'.)*
7. *Some genuinely testable theories, when found to be false, are still upheld by their admirers—for example by introducing ad hoc some auxiliary assumption, or by re-interpreting the theory ad hoc in such a way that it escapes refutation. Such a procedure is always possible, but it rescues the theory from refutation only at the price of destroying, or at least lowering, its scientific status. (I later described such a rescuing operation as a 'conventionalist twist' or a 'conventionalist stratagem'.)*

One can sum up all this by saying that the criterion of the scientific status of a theory is its falsifiability, or refutability, or testability.

Finally, Popper was careful to say that it is impossible to prove that Freudianism was *not true*, at least in part. But we *can* say that we simply don't *know* whether it's true because it does not make specific testable predictions. It may have many kernels of truth in it, but we can't tell. This is the essential "line of demarcation," as Popper called it, between science and pseudoscience.

36. The Three Buckets of Knowledge

The three most fundamental sources of knowledge are physics, math, and human history. They offer us endless learning and mental models. Here's how mastering the three buckets of knowledge can give you a deeper understanding of the world.

When we seek to understand the world, we're faced with a basic question: Where do I start? Which sources of knowledge are the most useful and the most fundamental?

FS takes its lead here from Charlie Munger, who argued that the "base" of your intellectual pyramid should be the great ideas from the big academic disciplines: Mental models (For a great book on the subject check out The Great Mental Models series.)

Similarly, Peter Kaufman's idea, presented above, is that we can learn the most fundamental knowledge from the three oldest and most invariant forms of knowledge: Physics and math, from which we derive the rules the universe plays by; biology, from which we derive the rules life on Earth plays by; and human history, from which we derive the rules humans have played by.

"Every statistician knows that a large, relevant sample size is their best friend. What are the three largest, most relevant sample sizes for identifying universal principles? Bucket number one is inorganic systems, which are 13.7 billion years in size. It's all the laws of math and physics, the entire physical universe. Bucket number two is organic systems, 3.5 billion years of biology on Earth. And bucket number three is human history, you can pick your own number, I picked 20,000 years of recorded human behavior. Those are the three largest sample sizes we can access and the most relevant."

— Peter Kaufman

With that starting point, we've explored a lot of ideas and read a lot of books, looking for connections among the big, broad areas of useful knowledge. Our search led us to a wonderful book called The Lessons of History, which we've previously discussed.

The book is a hundred-page distillation of the lessons learned in 50 years of work by two brilliant historians, Will and Ariel Durant. The Durants' spent those years writing a sweeping 11-book, 10,000-page synthesis of the major figures and periods in human history, with an admitted focus on Western civilization. (Although they admirably tackle Eastern civilization up to 1930 or so in the epic Our Oriental Heritage.) With *The Lessons of History*, the pair sought to derive a few major lessons learned from the long pull.

Let's explore a few ways in which the Durants' work connects with the three buckets of human knowledge that help us understand the world at a deep level.

Lessons of Geologic Time

Durant has a classic introduction for this kind of "big synthesis" historical work:

Since man is a moment in astronomic time, a transient guest of the earth, a spore of his species, a scion of his race, a composite of body, character, and mind, a member of a family and a community, a believer or doubter of a faith, a unit in an economy, perhaps a citizen in a state or a soldier in an army, we may ask under the corresponding heads—astronomy, geology, geography, biology, ethnology, psychology, morality, religion, economics, politics, and war—what history has to say about the nature, conduct, and prospects of man. It is a precarious enterprise, and only a fool would try to compress a hundred centuries into a hundred pages of hazardous conclusions. We proceed.

The first topic Durant approaches is our relationship to the physical Earth, a group of knowledge we can place in the second bucket, in Kaufman's terms. We must recognize that the varieties of geology and physical climate we live in have to a large extent determined the course of human history. (Jared Diamond would agree, that being a major component of his theory of human history.)

History is subject to geology. Every day the sea encroaches somewhere upon the land, or the land upon the sea; cities disappear under the water, and sunken cathedrals ring their melancholy bells. Mountains rise and fall in the rhythm of emergence and erosion; rivers swell and flood, or dry up, or change their course; valleys become deserts, and isthmuses become straits. To the geologic eye all the surface of the earth is a fluid form, and man moves upon it as insecurely as Peter walking on the waves to Christ.

There are some big, useful lessons we can draw from studying geologic time. The most obvious might be the concept of gradualism, or slow incremental change over time. This was most well-understood by Darwin, who applied that form of reasoning to understand the evolution of species. His hero was Charles Lyell, whose Principles of Geology created our understanding of a slow, move-ahead process on the long scale of geology.

And of course, that model is quite practically useful to us today — it is through slow, incremental, grinding change, punctuated at times by large-scale change when necessary and appropriate, that things move ahead most reliably. We might be reminded in the modern corporate world of General Electric, which ground ahead from an electric lamp company to an industrial giant, step-by-step over a long period which destroyed many thousands of lesser companies with less adaptive cultures.

We can also use this model to derive the idea of human nature as nearly fixed; it changes in geologic time, not human time. This explains why the fundamental problems of history tend to recur. We're basically the same as we've always been:

History repeats itself in the large because human nature changes with geological leisureliness, and man is equipped to respond in stereotyped ways to frequently occurring situations and stimuli like hunger, danger, and sex. But in a developed and complex civilization individuals are more differentiated and unique than in a primitive society, and many situations contain novel circumstances requiring modifications of instinctive response; custom recedes, reasoning spreads; the results are less predictable. There is no certainty that the future will repeat the past. Every year is an adventure.

Lastly, Mother Nature's long history also teaches us something of resilience, which is connected to the idea of grind-ahead change. Studying evolution helps us understand that what is fragile will eventually break under the stresses of competition: Most importantly, fragile relationships break, but strong win-win relationships have super glue that keeps parties together. We also learn that weak competitive positions are eventually rooted out due to competition and new environments, and that a lack of adaptiveness to changing reality is a losing strategy when the surrounding environment shifts enough. These and others are fundamental knowledge and work the same in human organizations as in Nature.

The Biology of History

Durant moves from geology into the realm of human biology: Our nature determines the "arena" in which the human condition can play out. Human biology gives us the rules of the chessboard, and the Earth and its inhabitants provide the environment in which we play the game. The variety of outcomes approaches infinity from this starting point. That's why this "bucket" of human knowledge is such a crucial one to study. We need to know the rules.

Thinking with the first "bucket" of knowledge — the mathematics and physics that drive all things in the universe — it's easy to derive that compounding multiplication can take a small population and make it a very large one over a comparatively short time. 2 becomes 4 becomes 8 becomes 16, and so on. But because we also know that the spoils of the physical world are finite, the "Big Model" of Darwinian natural selection flows naturally from the compounding math: As populations grow but their surroundings offer limitations, there must be a way to derive who gets the spoils.

Not only does this provide the basis for biological competition over resources, a major lesson in the second bucket, it also provides the basis for the political and economic

systems in bucket three of human history: Our various systems of political and economic organization are fundamentally driven by decisions on how to give order and fairness to the brutal reality created by human competition.

In this vein, we have previously discussed Durant's three lessons of biological history: Life is Competition. Life is Selection. Life must Replicate. These simple precepts lead to the interesting results in biology, and most relevant to us, to similar interesting results in human culture itself:

Like other departments of biology, history remains at bottom a natural selection of the fittest individuals and groups in a struggle wherein goodness receives no favors, misfortunes abound, and the final test is the ability to survive.

We do, however, need to be careful to think with the right “bucket” at the right time. Durant offers us a cautionary tale here: The example of the growth and decay of societies shows an area where the third bucket, human culture, offers a different reality than what a simple analogy from physics or biology might show. Cultural decay is not inevitable, as it might be with an element or a physical organism:

If these are the sources of growth, what are the causes of decay? Shall we suppose, with Spengler and many others, that each civilization is an organism, naturally and yet mysteriously endowed with the power of development and the fatality of death? It is tempting to explain the behavior of groups through analogy with physiology or physics, and to ascribe the deterioration of a society to some inherent limit in its loan and tenure of life, or some irreparable running down of internal force. Such analogies may offer provisional illumination, as when we compare the association of individuals with an aggregation of cells, or the circulation of money from banker back to banker with the systole and diastole of the heart.

But a group is no organism physically added to its constituent individuals; it has no brain or stomach of its own; it must think or feel with the brains or nerves of its members. When the group or a civilization declines, it is through no mystic limitation of a corporate life, but through the failure of its political or intellectual leaders to meet the challenges of change.

[...]

But do civilizations die? Again, not quite. Greek civilization is not really dead; only its frame is gone and its habitat has changed and spread; it survives in the memory of the race, and in such abundance that no one life, however full and long, could absorb it all. Homer has more readers now than in his own day and land. The Greek poets and philosophers are in every library and college; at this moment Plato is being studied by a hundred thousand discoverers of the “dear delight” of philosophy overspreading life with understanding thought. This selective survival of creative minds is the most real and beneficent of immortalities.

In this sense, the ideas that thrive in human history are not bound by the precepts of physics. Knowledge — the kind which can be passed from generation to generation in an accumulative way — is a unique outcome in the human culture bucket. Other biological creatures only pass down DNA, not accumulated learning. (Yuval Harari similarly declared that “The Cognitive Revolution is accordingly the point when history declared its independence from biology.”)

With that caveat in mind, the concept of passed-down ideas does have some predictable overlap with major mental models of the first two buckets of physics/math and biology. The first is compounding: Ideas and knowledge compound in the same mathematical way that money or population does. If I have an idea and tell my idea to you, we both have the idea. If we each take that idea and recombine it with another idea we already had, we now have three ideas from a starting point of only one. If we can each connect that one idea to two ideas we had, we now have five ideas between us. And so on — you can see how

compounding would take place as we told our friends about the five ideas and they told theirs. So the Big Model of compound interest works on ideas too.

The second interplay is to see that human ideas go through natural selection in the same way biological life does.

Intellect is therefore a vital force in history, but it can also be a dissolvent and destructive power. Out of every hundred new ideas ninety-nine or more will probably be inferior to the traditional responses which they propose to replace. No one man, however brilliant or well-informed, can come in one lifetime to such fullness of understanding as to safely judge and dismiss the customs or institutions of his society, for these are the wisdom of generations after centuries of experiment in the laboratory of history.

This doesn't tell us that the *best* ideas survive any more than natural selection tells us that the best *creatures* survive. It just means, at the risk of being circular, that the ideas most fit for propagation are the ones that survive for a long time. Most truly bad ideas tend to get tossed out in the vicissitudes of time either through the early death of their proponents or basic social pressure. But any idea that strikes a fundamental chord in humanity can last a very long time, even if it's wrong or harmful. It simply has to be memorable and have at least a kernel of intuitive truth.

37. At Some Point, You Have to Eat The Broccoli

It's a wonderful idea to try to find a set of systems and principles that "work better" for big swaths of your life. Better habits, better mental tendencies, better methods of inquiry, and so on. We're strong advocates of this approach, believing that good thinking and good decision making can be learned the same as a good golf swing can: Through practice and instruction.

So, read the below with this caveat in mind: Constant learning and self-improvement can and must be done for great life results.

Now, with that out of the way.

Progress Requires Effort

The problem with the search for self-improvement methods, including the kind of multidisciplinary thinking we espouse, is that many, perhaps most of them, are a snare and a delusion for most people. And there's a simple reason why: They won't actually do it.

Think about it. Isn't that the most common result? That you don't do it? For example, we heard from many people after we wrote a piece late last year on Reading 25 Pages a Day, a little practice that we think would benefit almost anyone in *creating* a very desirable reading habit.

What we suspect, though, is that even of the subset of people who felt so strongly about the idea that they contacted us, only a minority of them followed through and maintained to the habit to this day, ten months later.

The Failure to Implement Habits

Why is that? A huge part of it is Homeostasis: The basic self-regulating feedback loops that keep us repeating the same habits over and over. Predictable forces that keep us from changing *ourselves*, just as some forces keep us from changing *organizations*. (Or any self-regulating system.)

The failure to follow new systems and habits (mental or physical) follows this basic formula:

1. A system is proposed which makes the adherent think that they can live life a healthy life "without eating any broccoli." (Whether intended by the author or not.) You see this over and over: Money-making schemes, exercise-habit formation routines, 4-hour workweek promises, new cultural principles for businesses, and so on. Promises that lead people to think "healthy eating with no broccoli," so to speak. An easy fix.
2. Potential adherent to the "broccoli-free" system buys into the paradigm, and starts giving it a try.
3. Potential adherent realizes very quickly that either (A) The broccoli must, indeed, be eaten, or (B) The system does not work.

Do the Work

Now, with regards to the 25-pages a day "system" we outlined, we were careful not to make a "no broccoli" promise: All we said was that reading 25 pages per day was a habit that almost anyone could form and that it would lead them far. But you still have to do all the reading. You have to actually do the thing. That's the part where everyone falls away. We suspect that some people thought it would be easy to read 25 pages per day. That the pages would essentially "read themselves," or that the time to do so would spontaneously free up, just because they starting wanting it. This is never, ever the case. At some point, to be healthy, you do need to suck it up and eat some broccoli! And for many days in a row. Or, more to the point: The "failure point" with any new system; any method of improvement; any proposed solution to a life problem or an organization problem, is when

the homeostatic regulation kicks in, when we realize some part of it will be hard, new, or unnatural.

Even a really well-designed system can only cut up the broccoli into little pieces and sneak it into your mac-and-cheese. A popular example would be a fitness system whereby you do one pushup a day, then two pushups on the second day, then three the third day, and so on. It makes the habit digestible at first, as you get used to it. This is plenty smart. But eventually, if you're going to hang on to that habit, you'll have to do a whole lot of pushups every day! You can't just go back to plain mac-and-cheese, no broccoli. When the newness of the "one day at a time" system wears off, you'll be left with a *heaping* portion of broccoli. Will you continue eating it?

There is no free lunch. When you're evaluating a proposed improvement to your life or to your organization, you must figure out when and where the broccoli will get eaten, and understand that you will have to sacrifice something (even if it's just comfort) to get what you want. And if anyone ever promises you "no broccoli," it's a sham.

The willingness to pay the price is what separates people into two groups. On one hand, you have the people who want to want something and won't do anything hard to get it. These people are passive — life is always happening to them ... stuff is never perfect ... there is always something getting in the way. Soon enough they'll trade today's want for a new one, momentarily distracting themselves from their lack of progress. But nothing will ever change for these people. They'll never put in the work needed to make progress because they're not willing to pay the price or they're scared of failing. On the other hand, the second group is willing to do the work. They don't make excuses. They don't wait for perfection. They put their head down and get better every day. While they sometimes come up short, they get up and try again.

Which group do you think is more likely to succeed? Which group do you think is happier? Which group do you want to be a part of?

Remember that anything really worth doing is probably hard work, and will absolutely require you to do things you don't currently do, which will feel uncomfortable for a while. This is a "hard truth" we must all face. If it was easy, everyone would already be doing it.

Let's take the example of learning how to give better feedback. What could be a more useful skill? But actually *doing so*, actually following through with the idea, is not at all easy. You have to overcome your natural impulse to criticize. You have to get over your natural ego. You have to be very careful to watch your words, trying to decipher what will be *heard* when you deliver feedback. All of these are hard things to do, all of them unnatural. All will require some re-doubling to accomplish.

Thus, most people won't actually do it. This an Iron Rule of life: *Biological systems tend towards what is comfortable*. (Yes, human beings are "biological systems".)

But this Iron Rule is a problem and an opportunity wrapped together. As the saying goes, "*If you do what everyone else does, you'll get what everyone else gets*." If you can recognize that all things worth doing are hard at first, and that there is always some broccoli to be eaten, you are part of the way toward true advantageous differentiation. The rest is self-discipline.

We "go back" on our habits when they aren't truly formed yet. We think we're there, but we're really not — we've just been fooled by our sensory apparatus.

And the real and comforting truth is that you might really start liking, and even get used to eating, broccoli. Eating potato chips and candy will eventually feel like the uncomfortable and unnatural thing.

And that's when you know you've really got a great new discipline: Going back would feel like cutting off your hands.

38. How To Mentally Overachieve — Charles Darwin's Reflections On His Own Mind

We've written quite a bit about the marvelous British naturalist Charles Darwin, who with his Origin of Species created perhaps the most intense intellectual debate in human history, one which continues up to this day.

Darwin's *Origin* was a courageous and detailed thought piece on the nature and development of biological species. It's the starting point for nearly all of modern biology. But, as we've noted before, Darwin was not a man of pure IQ. He was not Issac Newton, or Richard Feynman, or Albert Einstein — breezing through complex mathematical physics at a young age.

Charlie Munger thinks Darwin would have placed somewhere in the *middle* of a good private high school class. He was also in notoriously bad health for most of his adult life and, by his son's estimation, a terrible sleeper. He really only worked a few hours a day in the many years leading up to the *Origin of Species*.

Yet his "thinking work" outclassed almost everyone. An incredible story.

In his autobiography, Darwin reflected on this peculiar state of affairs. What was he good at that led to the result? What was he so weak at? Why did he achieve better thinking outcomes? As he put it, his goal was to:

"Try to analyse the mental qualities and the conditions on which my success has depended; though I am aware that no man can do this correctly."

In studying Darwin ourselves, we hope to better appreciate our own strengths and weaknesses and, not to mention understand the working methods of a "*mental overachiever*."

Let's explore what Darwin saw in himself.

1. He did *not* have a quick intellect or an ability to follow long, complex, or mathematical reasoning. He may have been a bit hard on himself, but Darwin realized that he wasn't a "5 second insight" type of guy (and let's face it, most of us aren't). His life also proves how little that trait matters *if you're aware of it and counter-weight it with other methods*.

I have no great quickness of apprehension or wit which is so remarkable in some clever men, for instance, Huxley. I am therefore a poor critic: a paper or book, when first read, generally excites my admiration, and it is only after considerable reflection that I perceive the weak points. My power to follow a long and purely abstract train of thought is very limited; and therefore I could never have succeeded with metaphysics or mathematics. My memory is extensive, yet hazy: it suffices to make me cautious by vaguely telling me that I have observed or read something opposed to the conclusion which I am drawing, or on the other hand in favour of it; and after a time I can generally recollect where to search for my authority. So poor in one sense is my memory, that I have never been able to remember for more than a few days a single date or a line of poetry.

2. He did *not* feel easily able to write clearly and concisely. He compensated by getting things down quickly and then coming back to them later, thinking them through again and again. Slow, methodical....and ridiculously effective: For those who haven't read it, the Origin of Species is extremely readable and clear, even now, 150 years later.

I have as much difficulty as ever in expressing myself clearly and concisely; and this difficulty has caused me a very great loss of time; but it has had the compensating advantage of forcing me to think long and intently about every sentence, and thus I have been led to see errors in reasoning and in my own observations or those of others.

There seems to be a sort of fatality in my mind leading me to put at first my statement or proposition in a wrong or awkward form. Formerly I used to think about my sentences before writing them down; but for several years I have found that it saves time to scribble in a vile hand whole pages as quickly as I possibly can, contracting half the words; and

then correct deliberately. Sentences thus scribbled down are often better ones than I could have written deliberately.

3. He forced himself to be an incredibly effective and organized collector of information. Darwin's system of reading and indexing facts in large portfolios is worth emulating, as is the habit of taking down conflicting ideas immediately.

As in several of my books facts observed by others have been very extensively used, and as I have always had several quite distinct subjects in hand at the same time, I may mention that I keep from thirty to forty large portfolios, in cabinets with labelled shelves, into which I can at once put a detached reference or memorandum. I have bought many books, and at their ends I make an index of all the facts that concern my work; or, if the book is not my own, write out a separate abstract, and of such abstracts I have a large drawer full. Before beginning on any subject I look to all the short indexes and make a general and classified index, and by taking the one or more proper portfolios I have all the information collected during my life ready for use.

4. He had possibly the most valuable trait in any sort of thinker: A passionate interest in understanding reality and putting it in useful order in his head. This "Reality Orientation" is hard to measure and certainly does not show up on IQ tests, but probably determines, to some extent, success in life.

On the favourable side of the balance, I think that I am superior to the common run of men in noticing things which easily escape attention, and in observing them carefully. My industry has been nearly as great as it could have been in the observation and collection of facts. What is far more important, my love of natural science has been steady and ardent.

This pure love has, however, been much aided by the ambition to be esteemed by my fellow naturalists. From my early youth I have had the strongest desire to understand or explain whatever I observed,—that is, to group all facts under some general laws. These causes combined have given me the patience to reflect or ponder for any number of years over any unexplained problem. As far as I can judge, I am not apt to follow blindly the lead of other men. I have steadily endeavoured to keep my mind free so as to give up any hypothesis, however much beloved (and I cannot resist forming one on every subject), as soon as facts are shown to be opposed to it.

Indeed, I have had no choice but to act in this manner, for with the exception of the Coral Reefs, I cannot remember a single first-formed hypothesis which had not after a time to be given up or greatly modified. This has naturally led me to distrust greatly deductive reasoning in the mixed sciences. On the other hand, I am not very sceptical—a frame of mind which I believe to be injurious to the progress of science. A good deal of scepticism in a scientific man is advisable to avoid much loss of time, but I have met with not a few men, who, I feel sure, have often thus been deterred from experiment or observations, which would have proved directly or indirectly serviceable.

[...]

Therefore my success as a man of science, whatever this may have amounted to, has been determined, as far as I can judge, by complex and diversified mental qualities and conditions. Of these, the most important have been—the love of science—unbounded patience in long reflecting over any subject—industry in observing and collecting facts—and a fair share of invention as well as of common sense.

5. Most inspirational to us of average intellect, he outperformed his own mental aptitude with these good habits, surprising even himself with the results.

With such moderate abilities as I possess, it is truly surprising that I should have influenced to a considerable extent the belief of scientific men on some important points.

38. A Short List of Books for Doing New Things

Andrew Ng has quite the modern resume.

He founded Coursera, a wonderful website that gives anyone with Internet access the ability to take high level university courses on almost any topic. He founded the *Google Brain* project at Google, their deep learning research project intended to help bring about better artificial intelligence. Now he's the Chief Scientist at Baidu Research.

Ng is, unsurprisingly, *devoted to reading and learning*. As he puts it,

In my own life, I found that whenever I wasn't sure what to do next, I would go and learn a lot, read a lot, talk to experts. I don't know how the human brain works but it's almost magical: when you read enough or talk to enough experts, when you have enough inputs, new ideas start appearing. This seems to happen for a lot of people that I know.

When you become sufficiently expert in the state of the art, you stop picking ideas at random. You are thoughtful in how to select ideas, and how to combine ideas. You are thoughtful about when you should be generating many ideas versus pruning down ideas. [...]

I read a lot and I also spend time talking to people a fair amount. I think two of the most efficient ways to learn, to get information, are reading and talking to experts. So I spend quite a bit of time doing both of them. I think I have just shy of a thousand books on my Kindle. And I've probably read about two-thirds of them.

Ng thinks innovation and creativity can be *learned* — that they are pattern-recognition and combinatorial creativity exercises which can be performed by an intelligent and devoted practitioner with the right approach.

He also encourages the creation of new things; new businesses, new technologies. And on that topic, Ng has a few book recommendations. Given his list of accomplishments, the quality of his mind, and his admitted devotion to reading the printed word, it seems worth our time to check out the list.

Zero to One

The first is "Zero to One" by Peter Thiel, a very good book that gives an overview of entrepreneurship and innovation.

Crossing the Chasm / The Lean Startup

We often break down entrepreneurship into B2B ("business to business," i.e., businesses whose customers are other businesses) and B2C ("business to consumer").

For B2B, I recommend "Crossing the Chasm." For B2C, one of my favorite books is "The Lean Startup," which takes a narrower view but it gives one specific tactic for innovating quickly. It's a little narrow but it's very good in the area that it covers.

Talking to Humans

Then to break B2C down even further, two of my favorites are "Talking to Humans," which is a very short book that teaches you how to develop empathy for users you want to serve by talking to them.

Rocket Surgery Made Easy

Also, "Rocket Surgery Made Easy." If you want to build products that are important, that users care about, this teaches you different tactics for learning about users, either through user studies or by interviews.

The Hard Thing about Hard Things

Then finally there is "The Hard Thing about Hard Things." It's a bit dark but it does cover a lot of useful territory on what building an organization is like.

So Good They Can't Ignore You

For people who are trying to figure out career decisions, there's a very interesting one: "So Good They Can't Ignore You." That gives a valuable perspective on how to select a path for one's career.

39. Zero — Invented or Discovered?

It seems almost a bizarre question. Who thinks about whether zero was invented or discovered? And why is it important?

Answering this question, however, can tell you a lot about yourself and how you see the world.

Let's break it down.

"Invented" implies that humans created the zero and that without us, the zero and its properties would cease to exist.

"Discovered" means that although the symbol is a human creation, what it represents would exist independently of any human ability to label it.

So do you think of the zero as a purely mathematical function, and by extension think of all math as a human construct like, say, cheese or self-driving cars? Or is math, and the zero, a symbolic language that describes the world, the content of which exists completely independently of our descriptions?

The zero is now a ubiquitous component of our understanding.

The concept is so basic it is routinely mastered by the pre-kindergarten set. Consider the equation $3-3=0$. Nothing complicated about that. It is second nature to us that we can represent "nothing" with a symbol. It makes perfect sense now, in 2017, and it's so common that we forget that zero was a relatively late addition to the number scale.

Here's a fact that's amazing to most people: the zero is actually younger than mathematics. Pythagoras's famous conclusion — that in a right-angled triangle, the square of the hypotenuse is equal to the sum of the squares of the other two sides — was achieved without a zero. As was Euclid's entire *Elements*.

How could this be? It seems surreal, given the importance the zero now has to mathematics, computing, language, and life. How could someone figure out the complex geometry of triangles, yet not realize that nothing was also a number?

Tobias Dantzig, in *Number: The Language of Science*, offers this as a possible explanation: "The concrete mind of the ancient Greeks could not conceive the void as a number, let alone endow the void with a symbol." This gives us a good direction for finding the answer to the original question because it hints that you must first understand the concept of the void before you can name it. You need to see that nothingness still takes up space.

It was thought, and sometimes still is, that the number zero was invented in the pursuit of ancient commerce. Something was needed as a placeholder; otherwise, 65 would be indistinguishable from 605 or 6050. The zero represents "no units" of the particular place that it holds. So for that last number, we have six thousands, no hundreds, five tens, and no singles.

A happy accident of no great original insight, zero then made its way around the world. In addition to being convenient for keeping track of how many bags of grain you were owed, or how many soldiers were in your army, it turned our number scale into an extremely efficient decimal system. More so than any numbering system that preceded it (and there were many), the zero transformed the power of our other numerals, propelling mathematics into fantastic equations that can explain our world and fuel incredible scientific and technological advances.

But there is, if you look closely, a missing link in this story.

What changed in humanity that made us comfortable with confronting the void and giving it a symbol? And is it reasonable to imagine creating the number without understanding what it represented? Given its properties, can we really think that it started as a placeholder? Or did it contain within it, right from the beginning, the notion of defining the void, of giving it space?

In *Finding Zero*, Amir Aczel offers some insight. Basically, he claims that the people who discovered the zero must have had an appreciation of the emptiness that it represented. They were labeling a concept with which they were already familiar. He rediscovered the oldest known zero, on a stone tablet dating from 683 CE in what is now Cambodia.

On his quest to find this zero, Aczel realized that it was far more natural for the zero to first appear in the Far East, rather than in Western or Arab cultures, due to the philosophical and religious understandings prevalent in the region.

Western society was, and still is in many ways, a binary culture. Good and evil. Mind and body. You're either with us or against us. A patriot or a terrorist. Many of us naturally try to fit our world into these binary understandings. If something is "A," then it cannot be "not A." The very definition of "A" is that it is not "not A." Something cannot be both.

Aczel writes that this duality is not at all reflected in much Eastern thought. He describes the *catuskoti*, found in early Buddhist logic, that presents four possibilities, instead of two, for any state: that something is, is not, is both, or is neither.

At first, a typical Western mind might rebel against this kind of logic. My father is either bald or not bald. He cannot be both and he cannot be neither, so what is the use of these two other almost nonsensical options?

A closer examination of our language, though, reveals that the expression of the non-binary is understood, and therefore perhaps more relevant than we think. Take, for example, "you're either with us or against us." Is it possible to say "I'm both with you and against you"? Yes. It could mean that you are for the principles but against the tactics. Or that you are supportive in contrast to your values. And to say "I'm neither with you nor against you" could mean that you aren't supportive of the tactic in question, but won't do anything to stop it. Or that you just don't care.

Feelings, in particular, are a realm where the binary is often insufficient. Watching my children, I know that it's possible to be both happy and sad, a traditional binary, at the same time. And the zero itself defies binary categorization. It is something and nothing simultaneously.

Aczel reflects on a conversation he had with a Buddhist monk. "Everything is not everything — there is always something that lies outside of what you may think covers all creation. It could be a thought, or a kind of void, or a divine aspect. Nothing contains everything inside it."

He goes on to conclude that "Here was the intellectual source of the number zero. It came from Buddhist meditation. Only this deep introspection could equate absolute nothingness with a number that had not existed until the emergence of this idea."

Which is to say, certain properties of the zero likely were understood conceptually before the symbol came about — nothingness was a thing that could be represented. This idea fits with how we treat the zero today; it may represent nothing, but that nothing still has properties. And investigating those properties demonstrates that there is power in the void — it has something to teach us about how our universe operates.

Further contemplation might illuminate that the zero has something to teach us about existence as well. If we accept zero, the symbol, as being discovered as part of our realization about the existence of nothingness, then trying to understand the zero can teach us a lot about moving beyond the binary of alive/not alive to explore other ways of conceptualizing what it means to be.

39. Loops of Progress, or How Modern Are You?

On your way to work, you grab breakfast from one of the dozen coffee shops you pass. Most of the goods you buy get delivered right to your door. If you live in a large city and have a car, you barely use it, preferring Uber or ride-sharing services. You feel modern. Your parents didn't do any of this. Most of their meals were consumed at home, and they took their cars everywhere, in particular to purchase all the stuff they needed. You think of your life as being so different from theirs. It is. You think of this as progress. It isn't.

We tend to consider social development as occurring in a straight line: we progressed from A to B to C, with each step being more advanced and, we assume, better than the one before. This perception isn't always accurate, though. Part of learning from the past is appreciating that we humans have tried many different ways to organize ourselves, with lots of repetitions. If we want success now, we need to understand our past efforts in order to see what changes might be needed this time around.

Would you be surprised to learn that in Victorian London (the nineteenth century), the vast majority of people ate their food on the run? That ride sharing was common? Or that you could purchase everything you needed without ever leaving your house?

To be fair, these situations didn't exist in the exact instantiations that they do today.

Obviously, there was no amazon.com back then. But while the parallels are not exact, they are worth exploring, if only to remind us that no matter the array of pressures we face as a society, there are only so many ways we can organize ourselves.

To start with, street food was the norm. All classes except the very wealthy (thus, essentially, anyone who worked) ate on the run. At outdoor stalls or indoor counters. Food purchased from street vendors or chophouses (the Victorian equivalent of fast-food outlets). Food was purchased and consumed outside of the home, on the commute to or from work.

Why? Why would everyone from the middle classes to the working poor eat out?

Unlike today, eating out was cheaper then. As Judith Flanders explains in The Victorian City:

Today, eating out is more expensive than cooking at home, but in the nineteenth century the situation was reversed. Most of the working class lived in rooms, not houses. They might have had access to a communal kitchen, but more often they cooked in their own fireplace: to boil a kettle before going to work, leaving the fire to burn when there was no one home, was costly, time-consuming and wasteful. ... Several factors — the lack of storage space, routine infestations of vermin and being able, because of the cost, to buy food only in tiny quantities — meant that storing any foodstuff, even tea, overnight was unusual.

Even food delivery isn't new.

Every eating place expected to deliver meals, complete with cutlery, dishes and even condiments, which were brought by waiters who then stayed on, if wanted, to serve.

Endless processions of meals passed through the streets daily. ... Large sums of money were not necessary for this service.

People need to eat. It's fundamental. No matter what living conditions we find ourselves in, the drive away from starvation means that we are willing to experiment in how we organize to get our food.

Public transportation took hold in Victorian London and is another interesting point of comparison. Then, its use was not due to a sense of civic responsibility or concerns about the environment. Public transportation succeeded because it was faster. Most cities had grown organically, and streets were not designed for the volume they had to carry in the nineteenth century. There was no flow, and there were no traffic rules. The population was

swelling and road surfaces would be devastating to today's SUVs. It was simply painful to get anywhere.

Thus the options exploded. Buses and cabs to get about the city. Stagecoaches and the railroad for longer excursions (and commutes!). And the Underground. Buses "increased the average speed of travel to nearly six miles an hour; with the railway this figure rose to over twelve, sometimes double that." Public transportation allowed people to move faster, and "therefore, areas that had traditionally been on the edges of London now housed commuters."

As a direct consequence of the comparable efficiency of the public transportation system, "most people could not imagine ever owning a private carriage. It was not just the cost of the carriage itself, of the horse and its accoutrements — harnesses and so on — but the running costs: the feed and care of the horse, the stabling, as well as the taxes that were imposed on carriages throughout the century." As well as the staff. A driver, footmen, their salaries and uniforms.

A form of ride-sharing was also common then. For travel outside of the city, one could hire a post-chaise. "A post-chaise was always hired privately, to the passenger's own schedule, but the chaise, horses, driver and postboys all belonged to the coaching inn or a local proprietor."

Aside from the cost of owning your own transportation, neither the work day nor the city infrastructure was designed for reliance on individual transport. London in the nineteenth century (and to a large extent today) functioned better with an extensive public transport system.

[quote]There was no social safety net. You worked or you died.[/quote]

Finally, living in London in the nineteenth century was very much about survival. There was no social safety net. You worked or you died. And given the concentration of wealth in the top tier of society, there was a lot of competition among the working poor for a slight edge that would mean the difference between living another day and starvation.

This situation is likely part of the reason that sellers went to buyers, rather than the other way around. Unlike today, when so many bookstores are owned by the same company or when a conglomerate makes multiple brands of "unique" luxury goods, a watercress girl owned and sold only the watercress she could carry. And this watercress was no different from the bundles the girl one street over had. The competition to sell was fierce.

And so, as Flanders describes, in the first half of the nineteenth century, street vendors in all neighborhoods sold an astonishing array of goods and services. First chimney sweeps, then milkmaids; "the next sellers were the watercress girls, followed by the costermongers, then the fishmongers', the butchers' and the bakers' boys to take the daily orders." Next came the guy selling horsemeat.

Other goods regularly available from itinerant sellers in the suburbs included: footstools; embroidery frames; clothes horses, clothes-pegs and clothes line; sponges, chamois leathers, brushes and brooms; kitchen skewers, toasting-forks and other tinware; razors and penknives; trays, keyrings, and small items of jewellery; candlesticks, tools, trivets, pots and pans; bandboxes and hatboxes; blackleading for kitchen ranges and grates, matches and glue; china ornaments and crockery; sheets, shirts, laces, thread, ribbons, artificial flowers, buttons, studs, handkerchiefs; pipes, tobacco, snuff, cigars; spectacles, hats, combs and hairbrushes; firewood and sawdust.

You didn't have to leave your house to purchase items for meeting your daily needs.

This is not to say that Victorian London had everything figured out or that progress is always a loop. For example, there is no time in history in which it was better to be a woman than it is now, and modern medicine and the scientific method are significant steps up over what has come before. But reading these accounts of how London functioned almost two hundred years ago hints that a lot of what we consider modern innovations have been tried before.

Maybe ways of organizing come and go depending on time and place. When things are useful, they appear; as needs change, those things disappear. There really is no new way of doing business.

But we can look at the impact of social progress, how it shapes communities, and what contributes to its ebb and flow. Flanders notes that in the second half of the nineteenth century, there was a shift to going out to shop in stores. What changes did this give rise to? And how did those changes contribute to the loop we are experiencing and to our current desire to have everything brought to us?

40. Finding Truth in History

If we are to learn from the past, does the account of it have to be true? One would like to think so. Otherwise you might be preparing for the wrong battle. There you are, geared up for mountains, and instead you find swamps. You've done a bunch of reading, trying to understand the terrain you are about to enter, only to find it useless. The books must have been written by crazy people. You are upset and confused. Surely there must be some reliable, objective account of the past. How are you supposed to prepare for the possibilities of the future if you can't trust the accuracy of the reports on anything that has come before?

For why do we study history, anyway? Why keep a record of things that have happened? We fear that if we don't, we are doomed to repeat history; but often that doesn't seem to stop us from repeating it. And we have an annoying tendency to remember only the things which don't really challenge or upset us. But still we try to capture what we can, through museums and ceremonies and study, because somehow we believe that eventually we will come to learn something about why things happen the way they do. And armed with this knowledge, we might even be able to shape our future.

This "problem of historical truth" is explored by Isaiah Berlin in The Hedgehog and the Fox: An Essay on Tolstoy's View of History. He explains that Tolstoy was driven by a "desire to penetrate to first causes, to understand how and why things happen as they do and not otherwise." We can understand this goal – because if we know how the world really works, we know everything.

Of course, it's not that simple, and — spoiler alert — Tolstoy never figured it out. But Berlin's analysis can illuminate the challenges we face with history and help us find something to learn from.

Tolstoy's main problem with historical efforts at the time was that they were "nothing but a collection of fables and useless trifles. ... History does not reveal causes; it presents only a blank succession of unexplained events." Seen like this, the study of history is a waste of time, other than for trivia games or pub quizzes. Being able to recite what happened is supremely uninteresting if you can't begin to understand why it happened in the first place. But Tolstoy was also an expert at tearing down the theories of anyone who attempted to make sense of history and provide the why. He thought that they "must be imposters, since no theories can possibly fit the immense variety of possible human behavior, the vast multiplicity of minute, undiscoverable causes and effects which form that interplay of men and nature which history purports to record."

[quote]History is more than just factoids, but its complexity makes it difficult for us to learn exactly why things happened the way they did.[/quote]

And therein lies the spectrum of the problem for Tolstoy. History is more than just factoids, but its complexity makes it difficult for us to learn exactly why things happened the way they did. A battle is more than dates and times, but trying to trace the real impact of the decisions of Napoleon or Churchill is a fool's errand. There is too much going on – too many decisions and interactions happening in every moment – for us to be able to conclude cause and effect with any certainty. After leaving an ice cube to melt on a table, you can't untangle exactly what happened with each molecule from the puddle. That doesn't mean we can't learn from history; it means only that we need to be careful with the lessons we draw and the confidence we have in them.

Berlin explains:

There is a particularly vivid simile [in War and Peace] in which the great man is likened to the ram whom the shepherd is fattening for slaughter. Because the ram duly grows fatter, and perhaps is used as a bellwether for the rest of the flock, he may easily imagine that he is the leader of the flock, and that the other sheep go where they go solely in obedience to his will. He thinks this and the flock may think it too. Nevertheless the purpose of his

selection is not the role he believes himself to play, but slaughter – a purpose conceived by beings whose aims neither he nor the other sheep can fathom. For Tolstoy, Napoleon is just such a ram, and so to some degree is Alexander, and indeed all the great men of history.

Arguing against this view of history was N. I. Kareev, who said:

...it is men, doubtless, who make social forms, but these forms – the ways in which men live – in their turn affect those born into them; individual wills may not be all-powerful, but neither are they totally impotent, and some are more effective than others. Napoleon may not be a demigod, but neither is he a mere epiphenomenon of a process which would have occurred unaltered without him.

This means that studying the past is important for making better decisions in the future. If we can't always follow the course of cause and effect, we can at least discover some very strong correlations and act accordingly.

We have a choice between these two perspectives: Either we can treat history as an impenetrable fog, or we can figure out how to use history while accepting that each day might reveal more and we may have to update our thinking.

Sound familiar? Sounds a lot like the scientific method to me – a preference for updating the foundation of knowledge versus being adrift in chaos or attached to a raft that cannot be added to.

Berlin argues that Tolstoy spent his life trying to find a theory strong enough to unify everything. A way to build a foundation so strong that all arguments would crumble against it. Although that endeavor was ambitious, we don't need to fully understand the why of history in order to be able to learn from it. We don't need the foundation of the past to be solid and fixed in order to gain some insight into our future. We can still find some truth in history.

How?

Funnily enough, Berlin clarifies that Tolstoy “believed that only by patient empirical observation could any knowledge be obtained.” But he also believed “that simple people often know the truth better than learned men, because their observation of men and nature is less clouded by empty theories.”

Unhelpfully, Tolstoy's position amounts to “the more you know, the less you learn.”

The answer to finding truth in history is not to be found in Tolstoy's writing. He was looking for “something too indivisibly simple and remote from normal intellectual processes to be assailable by the instruments of reason, and therefore, perhaps, offering a path to peace and salvation.” He never was able to conclude what that might be.

But there might be an answer in how Berlin interprets Tolstoy's major dissonance in life, the discrepancy that drove him and was never resolved. Tolstoy “tried to resolve the glaring contradiction between what he believed about men and events, and what he thought he believed, or ought to believe.”

Finding truth in history is about understanding that this truth is not absolute. In this sense, truth is based on perspective. The perspective of the person who captured it and the person interpreting it. And the perspective of the translators and editors and primary sources. We don't get to be invisible observers of moments in the past, and we don't get to go into other minds. The best we can do is keep our eyes open and keep our biases in check. And what history can teach us is found not just in the moments it tries to describe, but also in what we choose to look at and how we choose to represent it.

41. Epistemology: How do you know that you know what you know?

There is no definite way to confirm that we know anything at all. Only from our direct experience can we claim any knowledge about the world.

The role of perception in knowledge

It is hard to imagine a world that exists outside of what we can perceive. In the effort to get through each day without crashing our cars or some other calamity, we make assumptions about the objects in our physical world. Their continuity, their behavior.

Some of these assumptions are based on our own experience, some on the knowledge imparted by others of their experience, and some on inferences of logic.

Experience, however, comes through the lens of perception. How things look, how they feel, how they sound.

Our understanding of, and interaction with, the world comes through particular constructs of the human body – eyes, ears, fingers, etc. Most people intuitively understand the subjectivity of some of our perceptions.

Colors look 'different' to people who are color blind. Our feeling of temperature is impacted by immediate contrast – People stepping outside the doors of an airport will have a different impression of the temperature if they have just come from Moose Jaw or Cancun. Even more substantial understandings come to us through the lens of our senses. We can see the shape of a tree, or we could close our eyes and infer the shape through touch, but in either case, or even combining the two, we are relying on our senses to impart an understanding of the physical world.

The question of what objectively 'is', is something that has long been one of the subjects of philosophy. Philosophers from Descartes to Kant have tried to describe our existence in such a way as to arrive at understanding of the physical world in which things can be conclusively known.

Descartes introduces the idea in his Meditations: "Surely whatever I had admitted until now as most true I received either from the senses or through the senses. However, I have noticed that the senses are sometimes deceptive; and it is a mark of prudence never to place our complete trust in those who have deceived us even once."

Descartes famously employed systematic doubt, questioning all knowledge conveyed by his experience in the world until the only knowledge he couldn't doubt was the fact that he could doubt.

Therefore I suppose that everything I see is false. I believe that none of what my deceitful memory represents ever existed. I have no sense whatever. Body, shape, extension, movement, and place are all chimeras. What then will be true? ... Thus, after everything has been most carefully weighed, it must finally be established that this pronouncement "I am, I exist" is necessarily true every time I utter it or conceive it in my mind. (Descartes, Meditations)

Descartes confirmed we have a self. Unfortunately this self could be the one we see in the mirror each morning or a brain in a vat. If the only thing we cannot doubt is that we can doubt, essentially that guarantees us having only the mechanism to doubt. No body. We could therefore be isolated brains, being manipulated by things unknown, our entire world a mirage.

How then can we hope to claim knowledge about the physical world?

For Locke, our understanding of the world comes from our experience of it. It is this experience that provides knowledge. He says, in his Essay Concerning Human Understanding:

Let us then suppose the mind to be, as we say, white paper, void of all characters, without any ideas: – How comes it to be furnished? Whence comes it by that vast store with the busy and boundless fancy of man has painted on it with an almost endless variety Whence

has it all the materials or reason and knowledge? To this I answer, in one word, from EXPERIENCE. In that all our knowledge is founded; and from that it ultimately derives itself.

He wrote that there were two types of qualities, ones that existed innately in an object or series of objects, such as size, number, or motion, and those that are wholly dependent on our perception of them, such as color or smell.

The particular bulk, number, figure, and motion of the parts of fire or snow are really in them, whether one's senses perceive them or no: and therefore they may be called real qualities, because they really exist in those bodies. But light, heat, whiteness, or coldness are not more really in them than sickness or pain is in manna. (Locke, An Essay Concerning Human Understanding)

Experience then, as long as we have an understanding of the limitations of our perception, will confer certain truths about the physical world we inhabit. For example, through experience we can claim knowledge of how many crows are perched on a telephone wire, but not how many of them have 'black' as an intrinsic property of their feathers.

Quite in opposition to this was George Berkeley (pronounced Bar-clay), for whom 'to be' was 'to be perceived'. Berkeley wrote in A Treatise Concerning the Principles of Human Knowledge:

Besides all that endless variety of ideas or objects of knowledge, there is likewise something which knows or perceives them and exercised divers operations, as willing, imagining, remembering, about them. This perceiving ... does not denote any one of my ideas, but a thing entirely distinct from them, wherein they exist or, which is the same thing, whereby they are perceived – for the existence of an idea consists in being perceived.

Because our knowledge of the world comes from our perception of it, it is impossible to conclusively know the existence of anything independent of our perception. Berkeley, wrote:

Hence, as it is impossible for me to see or feel anything without an actual sensation of that thing, so it is impossible for me to conceive in my thoughts any sensible thing or object distinct from the sensation or perception of it.

This line of inquiry ultimately results in the entire physical world being called into question, as Berkeley observed:

If we have any knowledge at all of external things, it must be by reason, inferring their existence from what is immediately perceived by sense. {However} it is granted on all hands (and what happens in dreams, frenzies, and the like, puts it beyond dispute) that it is possible we might be affected with all the ideas we have now, though no bodies existed without resembling them.

If we can not know things outside of perception, and our perceptions are entirely unreliable, where does that leave us? It certainly isn't useful to imagine your existence as the sum total of your knowledge, or that our experiences are inherently mistrustful.

What these philosophies can be useful for understanding though, is that often what we consider knowledge is more of a general social agreement on a somewhat consistent comprehension of the things before us. For example, we appreciate that the color green can be perceived differently by various people, but we organize our language based on a general understanding of the color green without worrying about the particular experience of green that any individual may have.

For David Hume, there definitely was a physical world, our perception of which was ultimately responsible for all of our ideas, no matter how complex or abstract. He wrote in An Enquiry Concerning Human Understanding:

When we analyze our thoughts or ideas, however compounded or sublime, we always find that they resolve themselves into such simple ideas as were copied from a precedent

feeling or sentiment. Even those ideas, which, at first view, seem the most wide of this origin, are found, upon a nearer scrutiny, to be derived from it.

Furthermore, since all of our perceptions of the physical world are coming from the same physical world, and the nature of perceiving works more or less the same in each person, we can achieve a consistency in our understanding.

So although it may not be possible to know things with the same certainty as knowing oneself, or to be able to really describe the construct of the world outside of our perception of it, at least we can get along with each other because of a general consistency of experience.

However, this experience still admits to a certain fragility. There is no guarantee that past experiences will be consistent with future ones. In *An Enquiry Concerning Human Understanding*, Hume observes:

Being determined by custom to transfer the past to the future, in all our inferences; where the past has been entirely regular and uniform, we expect the event with the greatest assurance and leave no room for any contrary supposition. But where different effects have been found to follow from causes, which are to appearance exactly similar, all these various effects must occur to the mind in transferring the past to the future, and enter into our consideration, when we determine the probability of the event.

To simultaneously understand all effects when considering an event in the future is not necessarily a limitation, thanks to our amazingly sophisticated brains. Immanuel Kant thought that the way we process the information provided by our senses was an important component of knowledge. Kant wrote in the *Prolegomena to Any Future Metaphysics*:

The difference between truth and dreaming is not ascertained by the nature of the representations which are referred to objects (for they are the same in both cases), but by their connection according to those rules which determine the coherence of the representation in the concept of an object, and by ascertaining whether they can subsist together in experience or not.

Kant did not support the view that the existence of objects was called into question because of the subjectivity of the perceptions by which we must experience them, but neither that all knowledge of the physical world comes from experience. Kant argued: *Experience teaches us what exists and how it exists, but never that it must necessarily exist so and not otherwise. Experience therefore can never teach us the nature of things in themselves.*

Knowledge then, is made up of things we infer, things we experience, and the way our brain processes both. The great metaphysical question of 'Why it is all this way?' may always be out of our reach.

Understanding some of this metaphysical uncertainty in knowledge does not mean that we have to give up on knowing anything. It simply points to a certain subjectivity, an allowance for different conceptions of the world. And hopefully it offers a set of tools with which to evaluate or build claims of knowledge.

42. The Narratives of History: Applying Lessons from the Past

“History is written by the winners” is the popular view. But your winner may not be my winner. A lot depends on the narrative you are trying to build.

History is rewritten all the time.

Sometimes it is rewritten because new information has come to light, perhaps from an archeological find or previously classified documents. When this happens, it is exciting. We joyfully anticipate that more information will deepen our understanding.

But rewriting frequently happens in the service of building a cultural or national narrative. We highlight bits of the past that support our perceived identities and willfully ignore the details that don't fit. We like our history uncomplicated. It's hard for us to understand our groups or our countries, and by extension ourselves, as both good and not-good at the same time.

Culture is a collective memory. It's the interwoven stories that we use to explain who we are as nations, organizations, or just loosely formed groups.

Many of us belong to multiple cultural groups, but only one national group. Margaret MacMillan, in *The Uses and Abuses of History*, explains that “Collective memory is more about the present than the past because it is integral to how the group sees itself.” And “while collective memory is usually grounded in fact, it need not be.”

We have seen how people justify all kinds of mistakes to preserve the personal narratives they are invested in, and groups also engage in this behavior. Countries rewrite their histories, from the textbook up, to support how they see themselves now. Instinctively we may recoil from this idea, believing that it's better to turn over all the rocks and confront what is lurking underneath. However, as MacMillan writes, “It can be dangerous to question the stories people tell about themselves because so much of our identity is both shaped by and bound up with our history. That is why dealing with the past, in deciding on which version we want, or on what we want to remember and to forget, can become so politically charged.”

For example, when Canada's new war museum opened, controversy immediately ensued because part of the World War II exhibit called attention “to the continuing debate over both the efficacy and the morality of the strategy of the Royal Air Force's bomber command, which sought to destroy Germany's capacity to fight on by massive bombing of German industrial and civilian targets.” RAF veterans were outraged that their actions were considered morally ambiguous. Critics of the exhibit charged that the veterans should have the final say because, after all, “they were there.”

We can see that this rationale makes no sense. Galilean relativity shows that the pilots who flew the bombing campaigns are actually the least likely to have an objective understanding of the events. And the ends don't always justify the means. It is possible to do bad things in the pursuit of morally justified outcomes.

MacMillan warns that the danger of abusing history is that it “flattens out the complexity of human experience and leaves no room for different interpretations of the past.”

Which leaves us asking, What do we want from history? Do we want to learn from it, with the hopes that in doing so we will avoid mistakes by understanding the experiences of others? Or do we want to practice self-justification on a national level, reinforcing what we already believe about ourselves to justify what we did and what we are doing? After all, “you could almost always find a basis for your claims in the past if you looked hard enough.”

As with medicine, there is certain fallibility to history. Our propensity to fool ourselves with self-justified narratives is hard to overcome. If we selectively use the past only to reinforce our claims in the present, then the situation becomes precarious when there is pressure to change. Instead of looking as objectively as possible at history, welcoming historians who

challenge us, we succumb to confirmation bias, allowing only those interpretations that are consistent with the narrative we are invested in.

Consider what MacMillan writes about nationalism, which “is a very late development indeed in terms of human history.”

It all started so quietly in the nineteenth century. Scholars worked on languages, classifying them into different families and trying to determine how far back into history they went. They discovered rules to explain changes in language and were able to establish, at least to their own satisfaction, that texts centuries old were written in early forms of, for example, German or French. Ethnographers like the Grimm brothers collected German folk tales as a way of showing that there was something called the German nation in the Middle Ages. Historians worked assiduously to recover old stories and pieced together the history of what they chose to call their nation as though it had an unbroken existence since antiquity. Archaeologists claimed to have found evidence that showed where such nations had once lived, and where they had moved to during the great waves of migrations.

The cumulative result was to create an unreal yet influential version of how nations formed. While it could not be denied that different peoples, from Goths to Slavs, had moved into and across Europe, mingling as they did so with peoples already there, such a view assumed that at some point, generally in the Middle Ages, the music had stopped. The dancing pieces had fallen into their chairs, one for the French, another for the Germans and yet another for the Poles. And there history had fixed them as “nations.” German historians, for example, could depict an ancient German nation whose ancestors had lived happily in their forests from before the time of the Roman Empire and which at some time, probably in the first century A.D., had become recognisably “German.” So — and this was the dangerous question — what was properly the German nation’s land? Or the land of any other “nation”? Was it where the people now lived, where they had lived at the time of their emergence in history, or both?

Would the scholars have gone on with their speculations if they could have seen what they were preparing the way for? The bloody wars that created Italy and Germany? The passions and hatred that tore apart the old multinational Austria-Hungary? The claims, on historical grounds, by new and old nations after World War I for the same pieces of territory? The hideous regimes of Hitler and Mussolini with their elevation of the nation and the race to the supreme good and their breathtaking demands for the lands of others?

When we selectively reach back into the past to justify claims in the present, we reduce the complexity of history and of humanity. This puts us in an awkward position because the situations we are confronted with are inherently complex. If we cut ourselves off from the full scope of history because it makes us uncomfortable, or doesn’t fit with the cultural narrative in which we live, we reduce our ability to learn from the past and apply those lessons to the situations we are facing today.

MacMillan says, “There are also many lessons and much advice offered by history, and it is easy to pick and choose what you want. The past can be used for almost anything you want to do in the present. We abuse it when we create lies about the past or write histories that show only one perspective. We can draw our lessons carefully or badly. That does not mean we should not look to history for understanding, support and help; it does mean that we should do so with care.”

We need to accept that people can do great things while still having flaws. Our heroes don’t have to be perfect, and we can learn just as much from their imperfections as from their achievements.

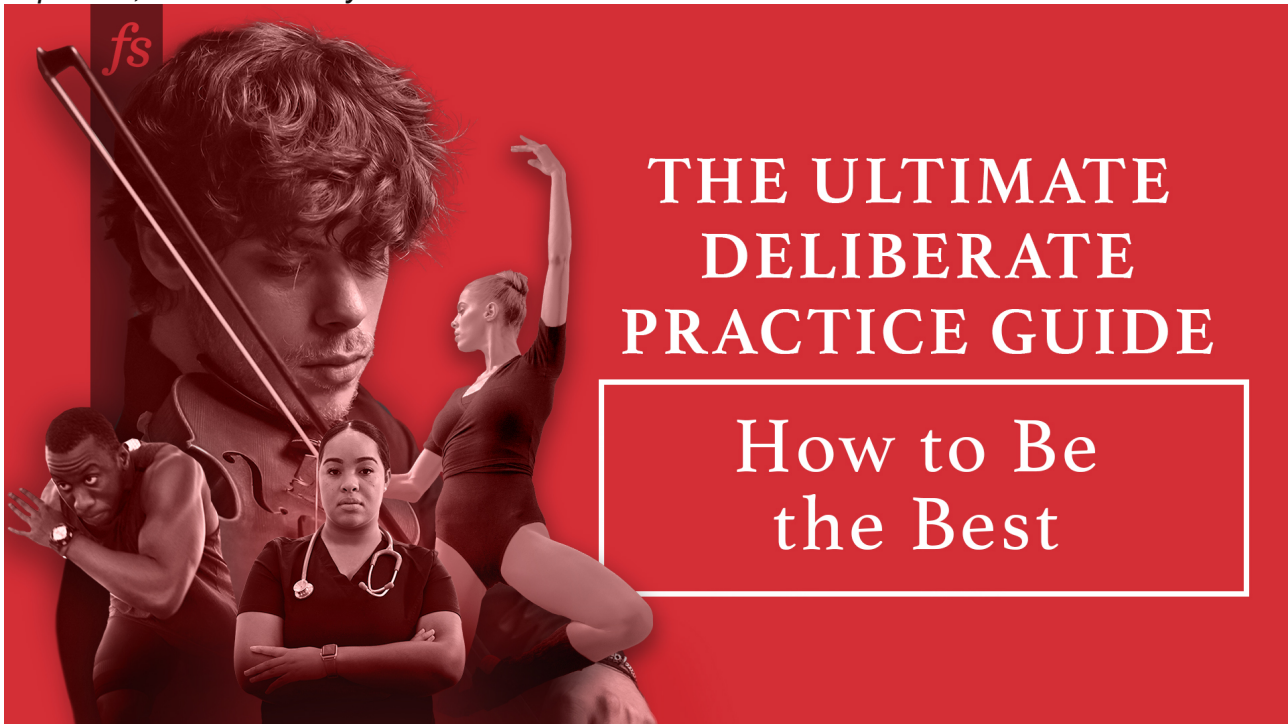

We have to allow that there are at least two sides to every story, and we have to be willing to listen to both. There are no conflicts in which one side doesn’t feel morally justified in their actions; that’s why your terrorist can be my freedom fighter. History can be an

important part of bridging this divide only if we are willing to lift up all the rocks and shine our lights on what is lurking underneath.

43. The Ultimate Deliberate Practice Guide: How to Be the Best

Everything You Need to Know to Improve Your Performance at Anything—For Beginners and Experts

Deliberate practice is the best technique for achieving expert performance in every field—including writing, teaching, sports, programming, music, medicine, therapy, chess, and business. But there's much more to deliberate practice than 10,000 hours. Read this to learn how to accelerate your learning, overcome the "OK" plateau, turn experience into expertise, and enhance your focus.

What is deliberate practice?

*“Engaged in the creative process we feel more alive than ever, because we are making something and not merely consuming, masters of the small reality we create. In doing this work, we are in fact creating ourselves.” —Robert Greene, *Mastery**

Deliberate practice is what turns amateurs into professionals. Across every field, deliberate practice is what creates top performers and what they use to stay at the top of their game. It's absolutely essential for expert performance.

As a general concept, “practice” means preparing. It's the act of repeatedly performing certain activities with the intention of improving a specific associated skill. We rehearse what to do in low-pressure situations so we'll be better when we use a skill in situations where something is actually at stake, such as in a competition or in the workplace.

Although this definition may seem obvious, it's crucial to distinguish between doing something and practicing it, because they're not always synonymous.

The key distinction between doing and practicing is that we're only practicing something when we do it in a way that makes us better at it—or at least with that intention.

Deliberate practice means practicing with a clear awareness of the specific components of a skill we're aiming to improve and exactly how to improve them. Unlike regular practice, in which we work on a skill by repeating it again and again until it becomes almost mindless, deliberate practice is a laser-focused activity. It requires us to pay unwavering attention to what we're doing at any given moment and whether it's an improvement or not.

Geoff Colvin summarizes deliberate practice as such in *Talent Is Overrated*:

Deliberate practice is characterized by several elements, each worth examining. It is activity designed specifically to improve performance, often with a teacher's help; it can be repeated a lot; feedback on results is continuously available; it's highly demanding

mentally, whether the activity is purely intellectual, such as chess or business-related activities, or heavily physical, such as sports; and it isn't much fun.

The extraordinary power of deliberate practice is that it aims at constant progress. Practitioners are not content with repeating a skill at the same level. They have metrics for measuring their performance. And they aspire to see those metrics get continuously better. While engaging in deliberate practice, we are always looking for errors or areas of weakness. Once we identify one, we establish a plan for improving it. If one approach doesn't work, we keep trying new ones until something does.

Using deliberate practice, we can overcome many limitations that we might view as fixed. We can go further than we might even think possible when we begin. Deliberate practice creates new physical and mental capabilities—it doesn't just leverage existing ones. The more we engage in deliberate practice, the greater our capabilities become. Our minds and bodies are far more malleable than we usually realize.

Deliberate practice is a universal technique, and you can employ it for whatever you're trying to be the best (or just get a little bit better) at. It's easiest to apply to competitive fields with clear measurements and standards, including music, dance, football/soccer, cricket, hockey, basketball, golf, horse riding, swimming, and chess.

But deliberate practice is also invaluable for improving performance in fields such as teaching, nursing, surgery, therapy, programming, trading, and investing. It can even accelerate your progress in widely applicable skills such as writing, decision-making, leadership, studying, and spoken communication.

The key in any area is to identify objective standards for performance, study top performers, and then design practice activities reflecting what they do. Recent decades have seen dramatic leaps in what people are capable of doing in many fields. The explanation for this is that we're getting better at understanding and applying the principles of deliberate practice. As a field advances, people can learn from the best of what those who came before them figured out. The result is that now average high-schoolers achieve athletic feats and children advance to levels of musical prowess that would have seemed unthinkable a century earlier. And there's little evidence to suggest we've reached the limits of our physical or mental abilities in any area whatsoever.

Many of us spend a lot of time each week practicing different skills in our lives and work. But we don't automatically get better just because we repeat the same actions and behaviors, even if we spend hours per day doing it. Research suggests that in areas such as medicine, people with many years of experience are often no better than novices—and may even be worse.

If we want to improve a skill, we need to know *what* exactly has to change and what might get us there. Otherwise, we plateau.

Some people will tell you it's only possible for anyone to improve at anything through deliberate practice, and any other sort of practice is a waste of time. This is an exaggeration. In reality, regular practice works for reinforcing and maintaining skills. It can also help us improve skills, particularly in the early stages of learning something. However, deliberate practice *is* the only way to:

1. Reach expert-level performance and enjoy competitive success
2. Overcome plateaus in our skill level
3. Improve at a skill much faster than through regular practice

If you're just doing something for fun and don't care about constantly improving at it, you don't need deliberate practice. For example, maybe you like to go for a walk around a local park in the afternoons to clear your head. Although you're practicing that walk each time you go, you probably don't care about increasing your walking speed day by day. It's

enough that the repetitions further ingrain the habit and help maintain a certain level of physical fitness. Not everything in life is a competition! But if you want to keep getting better at something as fast as possible or reach an expert level, deliberate practice is vital. Another important point to note is that deliberate practice isn't just a catchy name we came up with out of thin air. The term is largely attributed to Karl Anders Ericsson, one of the most influential figures of all time in the field of performance psychology. It's something many scientists have studied for decades. Everything we say here is supported by substantial academic research, particularly Ericsson's work. We'll also debunk the numerous myths swirling around deliberate practice as a concept and reveal some of its significant limitations. So if you're looking for quick hacks for overnight success, you might want to look elsewhere. If you want a realistic roadmap for improving your performance, read on.

If we want to improve a skill,
we need to know what exactly
has to change and what
might get us there.

“

fs

The elements of deliberate practice

“Life is not always a matter of holding good cards, but sometimes, playing a poor hand well.” —Jack London

In this section, we'll break down the fundamental elements of deliberate practice and exactly how to incorporate them into your practice sessions. As Ericsson wrote in *Peak*, *“No matter what the field, the most effective approach to improving performance is to follow a single set of principles.”* We'll explain why each component is crucial and how they apply to different fields, and we'll cover multiple ways to implement them depending on your goals.

Deliberate practice is structured and methodical

“Everyone has talent. What's rare is the courage to follow it to the dark places where it leads.” —Erica Jong

As humans, we're wired to want to do the easiest thing at all times in order to conserve energy. Put more simply, it's in our nature to be lazy. When we practice something a lot, we develop habits that become almost effortless to enact. While that's beneficial in many areas of our lives (and helps us survive), it's something we have to overcome in order to engage in deliberate practice. We can't expect constant improvement if we keep repeating the elements of a skill we already know how to do with ease. That's only enough if we're just having fun or want to reinforce our habits.

Deliberate practice is structured to improve specific elements of a skill through defined techniques. Practitioners focus above all on what they *can't* do. They seek out areas of weaknesses impacting their overall performance, then target those. At every stage, they set tailored, measurable goals in order to gauge whether their practice is effective at moving them forwards. Numbers are a deliberate practitioner's best friend.

If you want to reach an expert level of performance, you need to begin practice sessions with a plan in mind. You need to know what you're working on, why, and how you intend to improve it. You also need a way to tell if your improvement efforts aren't working and if you need to try a new tactic. Once you reach your goal for that particular component of the skill, it's time to identify a new area of weakness to work on next.

Having lots of little, realistic goals with a game plan for achieving them makes deliberate practice motivating. There's a sense of ongoing movement, yet the next step is always a realistic stretch. Day by day, the gains from deliberate practice may feel modest. But when we look back over a longer period of time, small bits of progress compound into gigantic leaps.

How to implement this: Take the skill you're aiming to improve and break it down into the smallest possible component parts. Make a plan for working through them in a logical order, beginning with the fundamentals, then building upon them. Decide which parts you'd like to master over the next month. Put your practice sessions in your calendar, then plan precisely which parts of the skill you're going to work on during each session.

Don't expect your plan to be perfect. You'll likely need to keep modifying it as you discover new elements or unexpected weaknesses. The most important thing is to always go into practice with a plan for what you're working on and how. Knowing what you're doing next is the best way to stay on track and avoid aimless time-wasting. That means seeking to keep figuring out what separates you from the next level of performance so you can concentrate on that.

Deliberate practice is challenging and uncomfortable

"One must develop an instinct for what one can just barely achieve through one's greatest efforts." —Albert Einstein (attributed)

Imagine the world from the perspective of a baby learning to walk for the first time. It's not usually an easy process. They need to develop a lot of new skills and capabilities. They need to build enough muscular strength to stand upright without support. And they need to learn how to coordinate their limbs well enough to move around. Along the way, a baby needs to develop numerous sub-skills, such as how to grip supports to pull themselves up. It likely takes thousands of attempts to master walking—as well as numerous, falls, collisions, and other mishaps. We might not remember the process as adults, but a baby learning to walk needs to spend many hours challenging themselves and moving incrementally out of their comfort zone.

If we want to use deliberate practice, we could do with learning a thing or two from babies. Deliberate practice isn't necessarily fun while we're doing it. In fact, most of the time it's a process of repeated frustration and failure. We have to fall down a dozen times for every step we take. That's the whole point.

Seeing as deliberate practice requires us to keep targeting our weakest areas, it means spending time doing stuff we're not good at. In the moment, that can feel pretty miserable. But the quickest route to improvement involves stepping outside of our comfort zones.

The reason why people who have spent decades doing something are not necessarily better than newbies is that they're liable to get complacent and stop pushing themselves. We need to keep attempting to do things that feel out of reach at the moment.

In his studies of elite violinists, Ericsson asked them to rate different practice activities by how enjoyable they were and how much they contributed to improving performance.

Invariably, there was an inverse correlation between the usefulness of an activity and its enjoyability. As Ericsson puts it in *Peak*:

The reason that most people don't possess these extraordinary physical capabilities isn't because they don't have the capacity for them, but rather because they're satisfied to live in the comfortable rut of homeostasis and never do the work that is required to get out of it. They live in the world of "good enough." The same thing is true for all the mental activities we engage in.

Elsewhere in the book, he writes *"This is a fundamental truth about any sort of practice: If you never push yourself beyond your comfort zone, you will never improve."* The interesting part is the more time you spend deliberately practicing, the more comfortable you'll become with being uncomfortable.

Daniel Coyle writes in *The Little Book of Talent*:

There is a place, right on the edge of your ability, where you learn best and fastest. It's called the sweet spot.... The underlying pattern is the same: Seek out ways to stretch yourself. Play on the edges of your competence. As Albert Einstein said, "One must develop an instinct for what one can just barely achieve through one's greatest efforts." The key word is 'barely.'

A quick way to assess if you're doing deliberate practice or just regular rote practice is to ask yourself if you ever feel bored or zone out during practice sessions. If the answer is yes, you're probably not practicing deliberately.

Deliberate practice isn't boring. Frustrating, yes. Maddening, yes. Annoying, even. But never boring. As soon as practicing a skill gets comfortable, it's time to up the stakes. Challenging yourself is about more than trying to work harder—it means doing new things. Pushing ourselves just beyond the limits of our abilities is uncomfortable, yet it's how we do our best—and indeed, it can be the source of some of our greatest moments of satisfaction. According to psychologist Mihaly Csikszentmihalyi, we often experience happiness as a result of entering a "flow" state, which occurs when we intensely focus on an activity that is challenging yet achievable. During moments of flow, we become so immersed in the activity that we lose any sense of time or of ourselves.

Noel Tichy, professor at the University of Michigan business school and the former chief of General Electric's famous management development center at Crotonville, puts the concept of practice into three zones: the comfort zone, the learning zone, and the panic zone.

Most of the time when we're practicing, we're really doing activities in our comfort zone. This doesn't help us improve because we can already do these activities easily. On the other hand, operating in the panic zone leaves us paralyzed, as the activities are too difficult and we don't know where to start. The only way to make progress is to operate in the learning zone, which are those activities that are just out of our reach.

Repetition inside the comfort zone does not equal deliberate practice. Deliberate practice requires that you operate in the learning zone and you repeat the activity a lot with feedback.

How to implement this: Each time you practice a component of a skill, aim to make it 10% harder than the level you find comfortable.

Once per month, have a practice session where you set yourself an incredibly ambitious stretch goal—not impossible, just well above your current level. Challenge yourself to see how close you can get to it. You might surprise yourself and find you perform far better than expected.

A common deliberate practice mistake is to plan a long practice session, then adjust the intensity of your practice to allow you to engage in a skill for the whole time. It's far more effective to engage in "sprints." Practice with the most intense focus you can manage for short periods of time, then take breaks. Seeing as you learn most when you stretch yourself beyond your current capabilities, shorter, more challenging practice periods are the way to go.

Deliberate practice requires rest and recovery time

“There is a time for many words, and there is also a time for sleep.” —Homer, The Odyssey

Seeing as deliberate practice is so challenging, it’s impossible to do it all day long. Across fields, top practitioners rarely spend more than around three to five hours per day on deliberate practice, at the high end. They may work for more hours than that per day, but few can sustain the mental energy to engage in deliberate practice for eight hours a day. Additional hours often result in diminishing negative returns, meaning more practice makes performance worse because it results in burnout. Geoff Colvin writes:

The work is so great that it seems no one can sustain it for very long. A finding that is remarkably consistent across disciplines is that four or five hours a day seems to be the upper limit of deliberate practice, and this is frequently accomplished in sessions lasting no more than an hour to ninety minutes.

Ericsson’s studies of elite violinists found they often took afternoon naps and slept an average of eight hours per night, considerably more than the average person. They were highly aware of the importance of sleep.

Even fitting in a single hour per day of deliberate practice is ample time to make substantial improvements, especially when we’re consistent with committing to it over the long haul. Continuous investments in success compound. In the long run, commitment pays off.

Not only do most deliberate practitioners not spend all day at it, they also devote a lot of time to recuperation and recovery. They sleep as much as their bodies need. They nap if necessary. They take frequent, refreshing breaks. Most of us understand that rest is necessary after physical activity. But we can underestimate its importance after mental activity, too. Deliberate practice needs to be sustainable for the long term. How long a person keeps at a skill is often far more important than how many hours a day they spend on it.

When you’re practicing deliberately, truly practice. When you’re recuperating, truly relax. No one can spend every waking hour on deliberate practice.

Sleep is a vital part of deliberate practice. Being asleep doesn’t mean you’re not still improving your skill. We consolidate memories at night, moving them from short-term to long-term memory. And we can’t exactly benefit from deliberate practice sessions if we don’t remember what we learn each time. Not only that, but sleep deprivation also results in a plethora of negative cognitive effects that impact performance. If we skimp on sleep, we’re likely to forget far more of what we learn during deliberate practice sessions, rendering them less useful.

When you’re not engaging in deliberate practice, your brain is still at work. During deliberate practice, we’re in focused mode. When we let our minds wander freely while at rest, we’re in diffuse mode. Although that time feels less productive, it’s when we form connections and mull over problems. Both modes of thinking are equally valuable, but it’s the harmony between them that matters. We can’t maintain the effort of the focused mode for long. At some point, we need to relax and slip into the diffuse mode. Learning a complex skill—a language, a musical instrument, chess, a mental model—requires both modes to work together. We master the details in focused mode, then comprehend how everything fits together in diffuse mode. It’s about combining creativity with execution. How to implement this: Make a list of activities you can engage in without too much conscious thought, letting yourself daydream while you do them. Common examples include going for a walk, washing the dishes, taking a shower, free-writing in a journal, playing with a toy like Lego, driving a familiar route, gardening, cooking, listening to music, or just gazing out the window. When you feel yourself getting tired or hitting a roadblock during deliberate practice, don’t keep pushing for too long. You want to be stretching yourself, not exhausting yourself. Instead, switch to one of those more relaxing activities

for at least five minutes. You'll likely come back to practice with new connections or at last feeling refreshed.

When you're practicing deliberately, truly practice. When you're recuperating, truly relax. No one can spend every waking hour on deliberate practice.

Deliberate practice involves constant feedback and measurement

"Deliberate practice is hard. It hurts. But it works. More of it equals better performance and tons of it equals great performance." —Geoff Colvin, *Talent Is Overrated*

Practicing something without knowing whether you are getting better is pointless. Yet that is what most of us do every day without thinking.

As we saw before, deliberate practice involves continuously stretching yourself to improve on weak areas of a skill. For that to work, practitioners require constant feedback about their current level of performance so they can identify what works for making it better. What gets measured gets managed. To engage in deliberate practice, you need a way of measuring the most instructive metrics related to your performance. Seeing how those metrics change is the sole way to know if practice is working or not. Top performers across fields tend to spend time examining their past performance with care to identify areas for improvement. For example, a tennis player might film themselves playing a match so they can go through the footage frame by frame afterward. This provides valuable feedback, because they can figure out what might have held them back during weaker moments. In fields such as sports and chess, measuring performance tends to be straightforward. In other areas such as business, measurements are harder to take, and there may be no established markers of success. The influence of random factors may also be stronger, making it less clear whether technique changes are actually having an influence or not. When you engage in deliberate practice, it's always important to be aware of how strongly correlated your practice and your performance are likely to be.

When measuring your performance, beware of vanity metrics. These are numbers that are easy to calculate and feel good to boost. But they don't actually move the needle towards the real improvements in performance that help you reach your goals. For example, let's say you're using deliberate practice to improve the skill of email marketing, as part of the wider goal of getting more customers for your business. The number of email subscribers is a vanity metric; the number of paying customers is a useful metric. It's completely possible to increase the former without a corresponding increase in the latter.

How to implement this: Identify the most significant metrics related to performance in your chosen skill and keep a record of them each time you practice. It's easy to fool yourself

without a clear record of how you're doing. You might want to break the skill down into a few different parts to measure it, but make sure you're not fixating on vanity metrics. Deliberate practice is most effective with the help of a coach or some kind of teacher *"The best teacher is not the one who knows most but the one who is most capable of reducing knowledge to that simple compound of the obvious and wonderful."* —H.L. Mencken (attributed)

Deliberate practice is most effective when conducted with some kind of coach who can give feedback, point out errors, suggest techniques for improvement, and provide vital motivation. Although mastering any skill requires a lot of time engaging in solitary practice, working with a coach at least some of the time is incredibly valuable. In some fields such as sports and music, it's common for a coach to be present all of the time. But most top performers benefit from a combination of coaching and solitary practice.

When we look at the lives of people who achieved great things, we often find that those who did so at a young age or in a shorter time than expected benefited from having fantastic teachers. For example, physicist Werner Heisenberg had the epiphany that led to the formulation of matrix mechanics a mere five years after commencing serious study of physics. But he no doubt benefited from the mentorship of Niels Bohr and Max Born, two of the foremost physicists at the time.

Even people at the most elite levels of performance across fields can benefit from specialist coaching. Engaging in something and teaching that thing are separate skills in themselves. The best practitioners are not always the best teachers because teaching is a skill in itself.

Ericsson explained that *"the best way to get past any barrier is to come at it from a different direction, which is one reason it is useful to work with a teacher or coach."* We often make the same mistakes again and again because we simply don't realize what we're doing. Our performance falls into ruts and we can't figure out why we're running into the same problem yet again.

A coach can see your performance from the outside, without the influence of overconfidence and other biases. They can identify your blind spots. They can help you interpret key metrics and feedback.

Ericsson went on to say that *"even the most motivated and intelligent student will advance more quickly under the tutelage of someone who knows the best order in which to learn things, who understands and can demonstrate the proper way to perform various skills, who can provide useful feedback, and who can devise practice activities designed to overcome particular weaknesses."* An experienced coach will have worked with many people on the same skill so they'll be able to advise on the best ways to structure practice. They'll know when you're just repeating what you find easy, and they'll be able to push you to the next level.

Teachers or coaches see what you miss and make you aware of where you're falling short. Geoff Colvin writes:

In some fields, especially intellectual ones such as the arts, sciences, and business, people may eventually become skilled enough to design their own practice. But anyone who thinks they've outgrown the benefits of a teacher's help should at least question that view. There's a reason why the world's best golfers still go to teachers.

But what if you don't have access to a coach? What if you don't have the means to hire one or one isn't available for your particular skill? In that case, it's still possible to apply the same principles that make a coach useful by yourself. Top performers across fields build the skill of metacognition, essentially making it possible for them to coach themselves.

Colvin explains:

The best performers observe themselves closely. They are in effect able to step outside themselves, monitor what is happening in their own minds, and ask how it's going.

Researchers call this metacognition—knowledge about your own knowledge, thinking

about your own thinking. Top performers do this much more systematically than others do; it's an established part of their routine.

...A critical part of self-evaluation is deciding what caused those errors. Average performers believe their errors were caused by factors outside their control: my opponent got lucky; the task was too hard; I just don't have the natural ability for this. Top performers, by contrast, believe they are responsible for their errors. Note that this is not just a difference of personality or attitude. Recall that the best performers have set highly specific, technique-based goals and strategies for themselves; they have thought through exactly how they intend to achieve what they want. So when something doesn't work, they can relate the failure to specific elements of their performance that may have misfired.

How to implement this: Don't expect the same teacher to suit you forever. We usually need different teachers as our skill level progresses because we outgrow them. One attribute of a good teacher is that they know when to tell a student to move on. As we reach expert levels of performance, we need teachers who are themselves experts. If they're always a step ahead, we can learn from their mistakes instead of making our own.

You get the best results from working with a coach if you show yourself to be receptive to constructive criticism, even if it's uncomfortable to hear. If you respond badly, you disincentivize them from telling you what's most useful to know. Top performers know the goal is to get better, not just to hear you're already great.

Deliberate practice requires intrinsic motivation

Persisting with deliberate practice despite its innate difficulty and discomfort requires a lot of motivation. But that motivation needs to be intrinsic, meaning that it comes from inside us because we find an activity enjoyable for its own sake. This is in contrast to extrinsic motivation, where we participate in an activity to gain an external reward or avoid a negative consequence. Yet another reason why rest is important for deliberate practice is because it helps sustain motivation.

Although deliberate practice can lead to external rewards for using a skill (such as winning a competition or getting a promotion), this should not be the sole reason for practicing it. Extrinsic motivation is unlikely to be enough to get us through the long period of struggle necessary to master a skill. Becoming proficient at anything means spending time failing repeatedly at it, during which there are few external rewards. But if we enjoy getting better for its own sake, we have more of a chance of persevering until our practice starts paying off. We can navigate obstacles because we want to see where the road might take us—the obstacles aren't roadblocks.

If you want to use deliberate practice to master a skill, you need to be willing to keep practicing it no matter what. Although brute force and rewarding yourself can be effective in the short run, it won't work forever. If you're planning to engage in deliberate practice to reach expert-level performance, make sure it's a prospect you feel excited about even if it won't always be fun.

Extrinsic motivation isn't always ineffective, however. People who engage in consistent, sustainable deliberate practice tend to be adept at knowing when and how they need to employ external incentives. It's important to reward yourself when you make progress in your practice and reflect on how far you've come, not just how far is left to go.

The need for intrinsic motivation is one reason why children who are pushed to develop a skill from a young age by their parents don't always end up reaching a high level of performance and often quit as soon as they can.

How to implement this: Make a list of the reasons you want to work on a skill and the benefits getting better at it might bring. Before you begin a deep practice session, reread the list to remind you of why you're bringing your full focus to something difficult. You could also list some of the benefits you've experienced from it in the past or include quotes from

top performers in your field you find inspiring. It might feel cheesy, but it can provide a powerful boost during particularly difficult practice moments. Try to focus on intrinsic reasons and benefits, such as feeling fulfilled.

Keep a “motivation diary” for one week (or longer if possible.) Try setting an alarm to go off every fifteen minutes during each practice session. When the alarm sounds, score your motivation level out of ten (or whichever scale you prefer.) At the end of the week, review your notes to look for any patterns. For example, you might find that you begin to feel demotivated once you’ve been practicing for more than an hour, or that you feel more motivated in the morning, or some other pattern. This information could be enlightening for planning future deliberate practice sessions, even if it may disrupt your focus at the time. Another method is to simply take notes each day, documenting your current level of motivation to work on your chosen skill. Pay attention to any recurring influences. For example, you might feel more motivated to improve your skill after speaking with a more proficient friend, but less motivated after a bad night’s sleep.

One potent option for sustaining motivation is to find someone who can be a reliable cheerleader for you. In an Ask Me Anything session for Farnam Street members, Tesla co-founder Marc Tarpenning explained that having a cofounder is vital for entrepreneurs because partnering with someone else helps sustain motivation. It’s rare that both founders feel demotivated on the same day. So if one is struggling, the other can provide the encouragement needed to stay resilient. Having someone to provide extrinsic motivation when you need it can help you persevere at deliberate practice. Your cheerleader doesn’t necessarily need to be working on the same skill themselves. They just need to understand your reasons and be willing to remind you of them when you start to doubt whether the hard work is worthwhile.

Deliberate practice takes time and can be a lifelong process

Although deliberate practice tends to result in much faster progress than normal practice, truly mastering a skill is a lifelong process. Reaching the top of a field can take years or even decades, depending on its competitiveness. As the bar for success in many areas keeps rising, more deliberate practice is required to stand out.

When we applaud the top people in any field, we often fail to appreciate that their success almost always came after many years of deliberate practice, which Robert Greene refers to in *Mastery* as “a largely self-directed apprenticeship that lasts some five to ten years [and] receives little attention because it does not contain stories of great achievement or discovery.” They may have ultimately benefited from a lucky break, but their extensive preparation meant they were ready for it. Great achievements tend to come later in life or even near the ends of careers. Those who succeeded young started very young.

Throughout Ericsson’s decades of research, he searched high and low for an example of a true prodigy: someone born with an innate, remarkable talent. He never found a single proven example. Instead, he discovered that people labeled as prodigies invariably put in enormous amounts of deliberate practice—they just often obscured it on purpose or started at a young age.

Although innate differences count when beginning to learn something (and people who begin with advantages may be more likely to persist), in the long run, deliberate practice always wins out.

David Shenk writes in *The Genius in All of Us*: “Short-term intensity cannot replace long-term commitment. Many crucial changes take place over long periods of time.

Physiologically, it’s impossible to become great overnight.”

According to psychologist John Hayes, creative genius tends to come after ten years of studying relevant knowledge and developing skills. Hayes referred to this as the “ten years of silence.” In a study of seventy-six composers with sufficient biographical data available listed in *The Lives of the Great Composers*, Hayes found they almost always created their first notable works (defined as being those for which at least five different recordings were

available at the time) at least ten years after commencing a serious study of music. Just three of the five hundred works Hayes included in his sample were composed after less than a decade of preparation—and those were produced in years eight or nine. In additional studies, Hayes found similar patterns for painters and poets.

Later research reinforces Hayes' findings, and any casual survey of the lives of people widely considered to be geniuses tends to show a similar pattern. Making a breakthrough takes time. When it seems like someone was an overnight success, there's almost always a long period of silent deliberate practice preceding it. Innate talents are just a starting point. If we want to master a skill, we need to commit to working on it for a lengthy period of time, likely with few rewards. While there are no assurances that with struggle comes reward, without it the odds are lower.

Not only do world-class performers spend a long time getting good at their core skill, those in creative fields tend to produce an enormous quantity of work before gaining recognition. For every piece of work we're familiar with, there are likely dozens or even hundreds of others few people remember or ever saw.

For example, British prime minister Winston Churchill was known for his masterful public speaking. One of his best-known speeches "We Shall Fight on the Beaches," given in June 1940, displayed the extent of his command of oration and helped build morale at the time. But it's hard to overstate how prolific Churchill was as a speaker, giving an estimated 3,000 speeches during his political career. For every speech—an average of one per week between 1900 and 1955—he used deliberate practice to prepare. He engaged in focused rehearsals in front of a mirror, taking notes as he went to inform modifications. Churchill also left nothing to chance, planning his pauses and movements in advance. As well as devising his own techniques for added impact, he memorized the works of some of history's most inspiring orators.

Although he doubtless began with a degree of innate talent (his father, Randolph Churchill, was also an admired orator), Churchill clearly used extensive deliberate practice to build upon it. While this impressive resume and history solidified his place on the throne of oratorical excellence, it's important to note that he wasn't a "born speaker"—in fact, he made many mistakes. And he learned from them. If you want to produce a masterpiece, you need to accept that you'll make a lot of less remarkable work first.

Deliberate practice requires intense focus

"You seldom improve much without giving the task your full attention." —Karl Anders Ericsson

The deeper we focus during deliberate practice sessions, the more we get out of them. Intense focus allows us to increase skills and break through plateaus. Developing your attention span can have a huge impact on your life. When asked about his success, Charlie Munger once said, *"I succeeded because I have a long attention span."*

The authors of *The Game Before the Game* write, *"If you can pay attention for only five minutes in practice, then take a break every five minutes. If you can pay attention for only twenty balls, don't hit fifty. To be able to practice longer and maintain the quality of the practice, train yourself to pay attention for longer periods of time....Productive practice is about how present you can stay with your intention and is measured in the quality of the experience as opposed to the quantity of time used."*

A benefit of getting constant feedback is that it shows you what moves the needle towards improved performance and what is just running in place. Certain practice activities can feel good without having any impact. Top performers prioritize knowing what to prioritize. They always start with the most important thing because anything else is a distraction.

Intense focus is a multiplier of everything else. Keeping an eye on key metrics enables top performers to identify and systematically remove distractions from their lives. To be the best, you need to focus on both the micro and macro level. You need to pay full attention to what you're doing in the current practice sessions, and you need to know how it fits into

the bigger picture of your desired trajectory. Deliberate practice is part of the exploit phase of selecting opportunities.

As the authors of the *International Handbook of Research in Professional and Practice-Based Learning* write, “*Practicing the right things is at the core of the theory of deliberate practice.*”

How to implement this: Put the big rocks in first. You can do anything, but you can’t do everything. Figure out which practice activities have the biggest influence on your performance and plan to engage in those first before you even consider activities that offer marginal gains.

Deliberate practice leverages the spacing effect

One reason why consistent deliberate practice sessions over the course of years are more effective than longer sessions for a shorter period of time relates to the spacing effect. We can’t approach learning a skill through deliberate practice in the same way we quite likely approached studying for tests in school. If we better understand how our minds work, we can use them in the optimal way for learning. By leveraging the spacing effect, we can encode valuable knowledge related to our particular skill for life during practice sessions. Memory mastery comes from repeated exposure to the same material. The spacing effect refers to how we are better able to recall information and concepts if we learn them in multiple sessions with increasingly large intervals between them. The most effective way to learn new information is through spaced repetition. It works for learning almost anything, and research has provided robust evidence of its efficacy for people of all ages—and even for animals.

Spaced repetition is also satisfying because it keeps us on the edge of our abilities (which, as we saw earlier, is a core element of deliberate practice.) Spaced sessions allow us to invest less total time to memorize than one single session, whereas we might get bored while going over the same material again and again in a single session. Of course, when we’re bored we pay less and less attention. The authors of *Focused Determination* put it this way:

There is also minimal variation in the way the material is presented to the brain when it is repeatedly visited over a short time. This tends to decrease our learning. In contrast, when repetition learning takes place over a longer period, it is more likely that the materials are presented differently. We have to retrieve the previously learned information from memory and hence reinforce it. All of this leads us to become more interested in the content and therefore more receptive to learning it.

We simply cannot practice something once and expect it to stick.

By engaging in deliberate practice on a regular basis, even if each practice session is short, we leverage the power of the spacing effect. Once we learn something through spaced repetition, it actually sticks with us. After a certain point, we may only need to revisit it every few years to keep our knowledge fresh. Even if we seem to forget something between repetitions, it later proves easier to relearn.

How to implement this: Forget about cramming. Each time you’re learning a new component of a skill, make a schedule for when you’ll review it. Typical systems involve going over information after an hour, then a day, then every other day, then weekly, then fortnightly, then monthly, then every six months, then yearly. Guess correctly and the information moves to the next level and is reviewed less often. Guess incorrectly and it moves down a level and is reviewed more often.

The history of deliberate practice

Karl Anders Ericsson: The expert on expertise

“*Learning isn’t a way of reaching one’s potential but rather a way of developing it.*” —Karl Anders Ericsson, *Peak*

The concept of deliberate practice is attributed to Florida State University psychologist Karl Anders Ericsson, who along with his collaborators performed pioneering research in the field of expert performance. Ericsson spent decades seeking to answer the question of what it takes to become really good at something difficult. His research often focused on medicine, music, and sports.

Ericsson's interest in expert performance kicked off in the late 1970s, when he began working with psychologist Bill Chase at Carnegie Mellon University to study short-term memory. Together, they began a series of experiments to see how many random digits it's possible to memorize after hearing them once. Ericsson and Chase used an undergrad named Steve Faloan as their guinea pig. For a few hours each week, they read out numbers and Faloan repeated as many as he could recall.

Although the experiment might sound dull, they uncovered something intriguing. In a 1982 paper entitled "Exceptional Memory," Ericsson and Chase summarized their findings. Previously, researchers believed the average person could hold just seven random digits in their short-term memory. Yet with careful practice, Faloan began to remember more and more numbers. At his peak and after 200 hours of practice, he could recall 82 digits. To assess if this was a fluke, Ericsson tried the same with a friend, Dario Donatelli. Five years later, Donatelli could recall 113 digits. Both he and Faloan went far beyond what seemed to be an immovable ceiling on human performance and blew past existing world records. The experience of seeing two people who started off with ordinary memories enhance their capabilities in such a drastic way inspired Ericsson to further study the effects of practice on skills. Could it be that extraordinary abilities came from extraordinary practice, not just innate ability?

Through his studies of expert performers in a range of fields, Ericsson concluded they practiced their skills in a fundamentally different way than amateur practitioners. Ericsson described this kind of practice as "deliberate" due to its methodical, hyper-conscious nature. He argued that experts become experts largely as a result of the way they practice. They may benefit from innate advantages, but their talents themselves are not innate. Ericsson also believed that the standards in many additional fields could be improved far beyond their current level if practitioners employed the principles of deliberate practice. Indeed, many fields have seen remarkable increases in their standards for high performance over time. Today, high-schoolers manage athletic feats that were once Olympic level and children play music once considered world-class. This is possible because of better training and knowledge of what it takes to be the best. The more we improve how we train, the more we expand our range of possible performance.

In 2016, Ericsson published *Peak: Secrets from the New Science of Expertise*, a popular science book condensing his learnings from thirty years of research. He also co-edited the 2006 *Cambridge Handbook of Expertise and Expert Performance*.

Malcolm Gladwell: The 10,000 hour rule

The widespread awareness of Ericsson's work outside the scientific community is in part a result of Malcolm Gladwell's 2008 book, *Outliers: The Story of Success*. In the book, Gladwell attributed unusual success in different fields to a mixture of lucky factors (such as when or where a person was born) and around 10,000 hours of practice. He based this figure on research, including Ericsson's, that suggested top performers tended to have put in about that amount of time before reaching peak performance.

Gladwell showed how the success of Bill Gates, the Beatles, and other outstanding performers is not so much to do with what they are like but rather where they come from. "The people who stand before kings may look like they did it all by themselves," Gladwell writes. "But in fact they are invariably the beneficiaries of hidden advantages and extraordinary opportunities and cultural legacies that allow them to learn and work hard and make sense of the world in ways others cannot."

The so-called “10,000 hours rule” caught on. It’s a catchy idea, and many people took it to mean that anyone can master anything if they just put the time in. Ericsson himself disputed Gladwell’s representations of his research, which led to the widespread belief that the time someone spends practicing predicts their success, without emphasizing the quality of their practice.

Although the backlash against Gladwell’s calculation has arguably been exaggerated, it’s important to stress that research into deliberate practice emphasizes quality of practice, not quantity. It’s all too possible to spend 10,000 hours engaging in a skill without serious improvements. For example, most of us spend hours per day typing, yet we don’t see continuous improvements in speed and quality because we’re not using deliberate practice.

The useful takeaway from the “10,000 hours rule” is simply that it takes a lot of work to become the best. There’s no magic number of practice sessions, and everyone’s path will look different. Just because successful people in a given field have spent around 10,000 hours practicing their key skill, that doesn’t mean every person who practices that skill for 10,000 hours will become successful.

The limitations and downsides of deliberate practice

Part of us wants to believe expert performance is something innate and magical so we can recuse ourselves from hard work. The other part of us wants to believe that it’s something earned through blood, sweat, and tears—that we too could achieve amazing performance, if only we could devote ourselves to something.

Deliberate practice, in reality, is far more complex and nuanced than many people would have you believe. It’s not a panacea, and it won’t solve all of your work- and art-related problems. Let’s take a look at some of the limitations of deliberate practice.

First of all, deliberate practice is a necessary but insufficient part of becoming a world-class performer. You can’t rise to the top without it. But it’s not enough on its own to be the absolute best in any field. Once you reach higher echelons for any skill, everyone is engaging in a lot of deliberate practice.

If you’re aiming at expertise or just really good performance, deliberate practice will most likely get you there. But the higher you rise, the more luck and randomness end up mattering. However much you engage in deliberate practice, you can’t control the chance events (good or bad) that dictate a great deal of life.

When we look at the lives of top performers, they often benefited from specific backgrounds or opportunities, in addition to engaging in deliberate practice. For example, if you’re trying to become a champion chess player, it’s a big boost if your mother was a champion chess player. Not only will you have potential genetic advantages, you’ll have also likely grown up hearing about chess, been encouraged to practice it from a young age, and have someone to turn to for advice.

Seeing as it takes years of consistent deliberate practice to master a skill, people who begin early in life have an advantage over those who start later on. That doesn’t mean you can’t become exceptional at something you discover well into adulthood (just look at [Julia Child](#) or check out the book [Guitar Zero](#)). But it does mean that people who begin deliberate practice as kids are more likely to enjoy the success that makes it possible to keep committing to it. If you’re trying to master a skill while also having to work an unrelated job, care for your family, and deal with the other myriad responsibilities of adult life, you likely will have less room for it than a ten-year-old.

People who discover they want to master a skill or are encouraged to do so by others early in life have an advantage. Once the opportunity for practice is in place, the prospects of high achievement take off. And if practice is denied or diminished, no amount of talent is going to get you there.

In addition to lucky circumstances, high performers benefit from a combination of deliberate practice and innate talents or physical advantages. However much you practice, certain physical limitations are insurmountable. For example, if you're 165 centimeters tall, you're unlikely to become a professional basketball player. There are some physical abilities, such as particular kinds of flexibility, that can only be developed at a young age when a person's skeletal structure is still forming. It's important to be realistic about your starting point and be aware of any limitations. But that doesn't mean you can't develop workarounds or even use them to your advantage.

Another downside of deliberate practice is that the level of focus it requires can mean practitioners miss out on other parts of life. Top performers often devote almost every waking hour to practice, recuperation from practice, and support activities. For example, a professional dancer might spend several hours a day on deliberate practice with all of the remaining hours going toward sleep, low-impact exercise, stretching, preparing nutritious food, icing his feet, and so on. There is enormous satisfaction in the flow states produced by deliberate practice, but practitioners can absolutely miss out on other sources of happiness, such as spending time with friends.

Deliberate practice is part of the exploit phase of new opportunities. Yet sometimes we can end up having too much grit. We can keep persevering with the skill we're practicing right now, remaining overly passionate, past the point where it serves us. We can wear ourselves out or get hurt or fail to realize when it's no longer worth practicing a skill. For example, a new technology might mean our skill is no longer valuable. If we keep on deliberately practicing due to sunk costs, we'll be unlikely to see many long-term benefits from it. A crucial skill in life is knowing when to pivot. Focusing too much on our goals can blind us to risks.

In some fields, expertise is hard to quantify or measure, which makes it less clear how to structure practice. There may be no single target to hit or universal rule for what improves performance.

A final limitation to keep in mind is that, as Ericsson explained, "*the cognitive and physical changes caused by training require upkeep. Stop training and they go away.*" If someone can't practice for a period of time, such as due to an injury or having a child, they're likely to see the skills they developed through deliberate practice deteriorate.

Summary

Deliberate practice isn't everything, but if you want to keep improving at a skill or overcome a plateau, you'll benefit from incorporating the principles mentioned in this article. To recap:

- Deliberate practice means practicing with a clear awareness of the specific components of a skill we're aiming to improve and exactly how to improve them.
- The more we engage in deliberate practice, the greater our capabilities become.
- Our minds and bodies are far more malleable than we usually realize.
- Deliberate practice is structured and methodical.
- Deliberate practice is challenging because it involves constantly pushing yourself out of your comfort zone.
- Deliberate practice requires constant feedback and measurement of informative metrics—not vanity metrics.
- Deliberate practice works best with the help of a teacher or coach.

- Continuing deliberate practice requires a great deal of intrinsic motivation.
- Deliberate practice requires constant, intense focus.
- Deliberate practice leverages the spacing effect—meaning a consistent commitment over time is crucial.
- If you're content with your current level of skill or just doing something for fun, you don't necessarily need to engage in deliberate practice
- Deliberate practice is best suited to pursuits where you're actively aiming for a high level of performance or to break beyond some kind of supposed limit.

44. The Terror of Totalitarianism Explained

We all hope totalitarianism — a form of government in which the state has no limits in authority and does whatever it wants — is a thing of the past.

Nazi Germany and Stalinist Russia showed what the end of humanity would look like, and it terrified us. But it's important to understand that totalitarianism didn't just spring up out of a mystical vacuum. As Hannah Arendt explains in *The Origins of Totalitarianism*, it is, rather, just one possibility along a path that most countries are on at one time or another. And that is why it is so important to understand what it is.

The People

One of the most disturbing things about Nazism in Germany is how quickly the country changed. They went from democracy to concentration camps in fewer than ten years. Most of us assume that the Germans of the time were different from us — *we'd* never fall for the kind of propaganda that Hitler spewed. And our democracy is too strong to be so easily dismantled. Right?

Wrong.

Arendt writes that “the success of totalitarian movements ... meant the end of two illusions of democratically ruled countries....” One illusion was that most citizens were politically active and were part of a political party. However,

... the [totalitarian] movements showed that the politically neutral and indifferent masses could easily be the majority in a democratically ruled country, [and] that therefore a democracy could function according to rules which are actively recognized by only a minority. The second democratic illusion exploded by the totalitarian movements was that these politically indifferent masses did not matter, that they were truly neutral and constituted no more than the inarticulate backward setting for the political life of the nation. In many modern democracies, we can see evidence of indifference and pervasive feelings of helplessness. There is low voter turnout and an assumption that things will be the way they are no matter what an individual does.

There is pent-up energy in apathy. Arendt suggests that the desire to be more than indifferent is what totalitarian movements initially manipulate until the individual is totally subsumed.

The disturbing factor in the success of totalitarianism is ... the true selflessness of its adherents: it may be understandable that a Nazi or Bolshevik will not be shaken in his conviction by crimes against people who do not belong to the movement...; but the amazing fact is that neither is he likely to waver when the monster begins to devour its own children and not even if he becomes a victim of persecution himself....

How does totalitarianism incite this kind of fanaticism? How does a political organization “succeed in extinguishing individual identity permanently and not just for the moment of collective heroic action”?

As Arendt demonstrates, both Nazi Germany and Stalinist Russia capitalized on tensions already present in society. There was essentially a massive rejection of the existing political system as ineffectual and self-serving.

The fall of protecting class walls transformed the slumbering majorities behind all parties into one great unorganized, structureless mass of furious individuals who had nothing in common except their vague apprehension that the hopes of party members were doomed, that, consequently, the most respected, articulate and representative members of the community were fools and that all the powers that be were not so much evil as they were equally stupid and fraudulent.

How does a totalitarian government harness this attitude of the masses? By completely isolating individuals through random “liquidating” (mass murder) so that “the most elementary caution demands that one avoid all intimate contacts, if possible – not in order to prevent discovery of one’s secret thoughts, but rather to eliminate, in the almost certain

case of future trouble, all persons who might have not only an ordinary cheap interest in your denunciation but an irresistible need to bring about your ruin simply because they are in danger [in] their own lives.”

It's important to understand that it is simple to isolate people who already feel isolated. When you feel disconnected from the system around you and the leaders it has, when you believe that neither your vote nor your opinion matters, it's not a huge leap to feel that your very self has no importance. This feeling is what totalitarianism figured out how to manipulate by random terror that severed any form of connection with other human beings.

Totalitarianism “demand[s] total, unrestricted, unconditional, and unalterable loyalty of the individual member. ... Such loyalty can be expected only from the completely isolated human being who, without any other social ties to family, friends, comrades, or even mere acquaintances, derives his sense of having a place in the world only from his belonging to a movement.”

The Politics and Propaganda

Totalitarianism does not have an end goal in the usual political sense. Its only real goal is to perpetuate its own existence. There is no one party line that, if you stick to it, will save you from persecution. Remember the random mass murders. Stalin repeatedly purged whole sections of his government — just because. The fear is a requirement. The fear is what keeps the movement going.

And how do they get there? How do they get this power?

Arendt argues that there is a “possibility that gigantic lies and monstrous falsehoods can eventually be established as unquestioned facts, that man may be free to change his own past at will, and that the difference between truth and falsehood may cease to be objective and become a mere matter of power and cleverness, of pressure and infinite repetition.”

This battle with truth is something we see today. Opinions are being given the same weight as facts, leading to endless debates and the assumption that nothing can be known anyway.

It is this turning away from knowledge that opens the doors to totalitarianism. “Before mass leaders seize the power to fit reality to their lies, their propaganda is marked by its extreme contempt for facts as such, for in their opinion fact depends entirely on the power of man who can fabricate it.”

These fabrications form the basis of the propaganda, with different messages crafted for different audiences. Arendt makes the point that “the necessities for propaganda are always dictated by the outside world and that the movements themselves do not actually propagate but indoctrinate.” Thus, propaganda can be understood as directed to those who are out of the control of the totalitarian movement, and it is used to convince them of its legitimacy. Then, once you are on the inside, it's about breaking down the individuality of the citizens until there is nothing but a “subdued population.”

The success of the propaganda directed internally demonstrated that “the audience was ready at all times to believe the worst, no matter how absurd, and did not particularly object to being deceived because it held every statement to be a lie anyhow.”

The Power

What does totalitarian rule look like? These states are not run by cliques or gangs. There is no protected group getting rich from this control of the masses. And no one is outside the message. For example, “Stalin ... shot almost everybody who could claim to belong to the ruling clique and ... moved the members of the Politburo back and forth whenever a clique was on the point of consolidating itself.”

Why no clique? One reason is that the goal of totalitarianism is not the welfare of the state. It is not economic prosperity or social advancement.

The reason why the ingenious devices of totalitarian rule, with their absolute and unsurpassed concentration of power in the hands of a single man, were never tried before

is that no ordinary tyrant was ever mad enough to discard all limited and local interests — economic, national, human, military — in favor of a purely fictitious reality in some indefinite distant future.

Since independent thinkers are a threat, they are among the first to be purged. Bureaucratic functions are duplicated and layered, with people being shifted all the time. *This regular violent turnover of the whole gigantic administrative machine, while it prevents the development of competence, has many advantages: it assures the relative youth of officials and prevents a stabilization of conditions which, at least in time of peace, are fraught with danger for totalitarian rule....*

Any chances of discontent and questioning of the status quo are eliminated by this perpetual rising of the newly indoctrinated.

The humiliation implicit in owing a job to the unjust elimination of one's predecessor has the same demoralizing effect that the elimination of the Jews had upon the German professions: it makes every jobholder a conscious accomplice in the crimes of the government....

Totalitarianism in power is about keeping itself in power. By preemptively removing large groups of people, the system neutralizes all those who might question it.

Possibly the one ray of hope in these systems is that because they pay no attention to actually governing, they are not likely to be sustainable in the long run.

The incredibility of the horrors is closely bound up with their economic uselessness. The Nazis carried this uselessness to the point of open anti-utility when in the midst of the war, despite the shortage of building material and rolling stock, they set up enormous, costly extermination factories and transported millions of people back and forth. In the eyes of a strictly utilitarian world the obvious contradiction between these acts and military expediency gave the whole enterprise an air of mad unreality.

But in the meantime, what these regimes create is so devastating to humanity that it would be naive to assume that humanity will always bounce back. "They have corrupted all human solidarity. Here the night has fallen on the future. When no witnesses are left, there can be no testimony."

Even though totalitarianism doesn't produce countries with a variety of strengths and a robustness to fight off significant challenges, they should not be easily dismissed. The carnage they create tears apart all social fabric. And we must not assume that they exist only in the past. Thus, from Hannah Arendt, a final word of caution: "Totalitarian solutions may well survive the fall of totalitarian regimes in the form of strong temptations which will come up whenever it seems impossible to alleviate political, social, or economic misery in a manner worthy of man."

45. Pain Plus Reflection Equals Progress

Our most painful moments are also our most important. Rather than run from pain, we need to identify it, accept it, and learn how to use it to better ourselves.

Our images of learning are filled with positive thoughts about how we learn from others. We read memoirs from the titans of industry, op-ed pieces from thought leaders, and gobble up the latest letters from CEOs in an attempt to absorb as much knowledge as we can. But it may surprise you that we're missing one of the most obvious sources of learning: ourselves.

Pain is something we all try to avoid, both instinctively and consciously. However, if we want to achieve great things in life, we need to change our relationship with pain.

Ray Dalio, the longtime leader of Bridgewater, the largest hedge fund in the world, argues in his book Principles that pain "is a signal that you need to find solutions so you can progress." Only by exploring it and reflecting on it can we start to learn and evolve.

There is an adage that states, "if you're not failing, then you're not really pushing the limits of what's possible." Sometimes when we push ourselves, we fall, and sometimes we break through. When we fall, the key is to reflect on our failures. However, doing that in the moment is often a very painful process that goes against human nature.

Our painful moments are important moments. When we confront something painful, we are left with a choice: accept an ugly and painful truth or embrace a beautiful delusion. Many of us opt for the latter, and it slows our progress.

We've known about our tendency to prefer delusion for a long time. We've watched others make mistakes and fail to learn from them. They are blind to the mistakes that are so clear to us. They run from the pain that could be the source of learning. They become comfortable operating without pain. They become comfortable protecting the version of themselves that existed yesterday, not the version of themselves that's better than they were yesterday.

Rather than running from pain, we need to identify it, accept it, and learn how to use it to better ourselves. In order for us to adapt, we need to learn from uncomfortable moments. We need to value a tough-love approach, where people show us what we're missing and help us improve.

You have a choice: You can prefer that the people around you fail to point out your blind spots, or you can prefer that they do. If you want them to, it's going to be uncomfortable. It's going to be awkward. It's going to hurt. Embracing this approach, however, means that you will learn faster and go further. It's a great example of "first-order negative, subsequent positive." This means the first step is the hardest and it hurts, but after that, you reap the benefits.

Of course, many of us prefer to tell ourselves that we have no weaknesses. That the world is wrong and we are right. We hide our weaknesses not only from others but also from ourselves. Being open about weaknesses means being open about who we are in the moment. It doesn't mean that's who we are forever. But we can't improve what we can't see.

Many of the people I talk to on the podcast have endured setbacks that seemed catastrophic at the time. Dalio, for instance, punched his boss in the face. Annie Duke lost millions. Countless others have been divorced, fired, or otherwise in a position where they felt unable to go on. I've been there too. It's in these moments, however, that a meaningful part of life happens. Life is about what you do in the painful moments; the choices you make and the path you choose.

The easy road is staying the same, avoiding pain and ignoring your flaws. The hard road is embracing the pain, examining your mistakes, and shining a light on your blind spots. This is the path to seeing reality and leaving your self-made bubble behind.

The people who have succeeded in life have learned to embrace pain and not be afraid to fall. They've learned from their failures and used them to make themselves better. Embracing pain is not easy but it is a choice that can lead to personal growth and success. Don't be afraid to confront your painful moments, be open about your weaknesses and strive to improve yourself, it's the only way to truly achieve greatness in life.

46. Double Loop Learning: Download New Skills and Information into Your Brain

We're taught single loop learning from the time we are in grade school, but there's a better way. Double loop learning is the quickest and most efficient way to learn anything that you want to "stick."

So, you've done the work necessary to have an opinion, learned the mental models, and considered how you make decisions. But how do you now implement these concepts and figure out which ones work best in your situation? How do you know what's effective and what's not? One solution to this dilemma is double loop learning.

We can think of double loop learning as learning based on Bayesian updating — the modification of goals, rules, or ideas in response to new evidence and experience. It might sound like another piece of corporate jargon, but double loop learning cultivates creativity and innovation for both organizations and individuals.

"Every reaction is a learning process; every significant experience alters your perspective."

— Hunter S. Thompson

Single Loop Learning

The first time we aim for a goal, follow a rule, or make a decision, we are engaging in single loop learning. This is where many people get stuck and keep making the same mistakes. If we question our approaches and make honest self-assessments, we shift into double loop learning. It's similar to the Orient stage in John Boyd's OODA loop. In this stage, we assess our biases, question our mental models, and look for areas where we can improve. We collect data, seek feedback, and gauge our performance. In short, we can't learn from experience without reflection. Only reflection allows us to distill the experience into something we can learn from.

In Teaching Smart People How to Learn, business theorist Chris Argyris compares single loop learning to a typical thermostat. It operates in a homeostatic loop, always seeking to return the room to the temperature at which the thermostat is set. A thermostat might keep the temperature steady, but it doesn't learn. By contrast, double loop learning would entail the thermostat's becoming more efficient over time. Is the room at the optimum temperature? What's the humidity like today and would a lower temperature be more comfortable? The thermostat would then test each idea and repeat the process. (Sounds a lot like Nest.)

Double Loop Learning

Double loop learning is part of *action science* — the study of how we act in difficult situations. Individuals and organizations need to learn if they want to succeed (or even survive). But few of us pay much attention to exactly how we learn and how we can optimize the process.

Even smart, well-educated people can struggle to learn from experience. We all know someone who's been at the office for 20 years and claims to have 20 years of experience, but they really have one year repeated 20 times.

Not learning can actually make you worse off. The world is dynamic and always changing. If you're standing still, then you won't adapt. Forget moving ahead; you have to get better just to stay in the same relative spot, and not getting better means you're falling behind.

Many of us are so focused on solving problems as they arise that we don't take the time to reflect on them after we've dealt with them, and this omission dramatically limits our ability to learn from the experiences. Of course, we want to reflect, but we're busy and we have more problems to solve — not to mention that reflecting on our idiocy is painful and we're predisposed to avoid pain and protect our egos.

Reflection, however, is an example of an approach I call first-order negative, second-order positive. It's got very visible short-term costs — it takes time and honest self-assessment about our shortcomings — but pays off in spades in the future. The problem is that the future is not visible today, so slowing down today to go faster at some future point seems like a bad idea to many. Plus with the payoff being so far in the future, it's hard to connect to the reflection today.

The Learning Dilemma: How Success Becomes an Impediment

Argyris wrote that many skilled people excel at single loop learning. It's what we learn in academic situations. But if we are accustomed only to success, double loop learning can ignite defensive behavior. Argyris found this to be the reason learning can be so difficult. It's not because we aren't competent, but because we resist learning out of a fear of seeming incompetent. Smart people aren't used to failing, so they struggle to learn from their mistakes and often respond by blaming someone else. As Argyris put it, "their ability to learn shuts down precisely at the moment they need it the most."

In the same way, a muscle strengthens at the point of failure, we learn best after dramatic errors.

The problem is that single loop processes can be self-fulfilling. Consider managers who assume their employees are inept. They deal with this by micromanaging and making every decision themselves. Their employees have no opportunity to learn, so they become discouraged. They don't even try to make their own decisions. This is a self-perpetuating cycle. For double loop learning to happen, the managers would have to let go a little. Allow someone else to make minor decisions. Offer guidance instead of intervention. Leave room for mistakes. In the long run, everyone would benefit. The same applies to teachers who think their students are going to fail an exam. The teachers become condescending and assign simple work. When the exam rolls around, guess what? Many of the students do badly. The teachers think they were right, so the same thing happens the next semester.

Many of the leaders Argyris studied blamed any problems on "unclear goals, insensitive and unfair leaders, and stupid clients" rather than making useful assessments. Complaining might be cathartic, but it doesn't let us learn. Argyris explained that this defensive reasoning happens even when we want to improve. Single loop learning just happens to be a way of minimizing effort. We would go mad if we had to

rethink our response every time someone asked how we are, for example. So everyone develops their own “theory of action—a set of rules that individuals use to design and implement their own behavior as well as to understand the behavior of others.” Most of the time, we don’t even consider our theory of action. It’s only when asked to explain it that the divide between how we act and how we think we act becomes apparent. Identifying the gap between our espoused theory of action and what we are actually doing is the hard part.

The Key to Double Loop Learning: Push to the Point of Failure

The first step Argyris identified is to stop getting defensive. Justification gets us nowhere. Instead, he advocates collecting and analyzing relevant data. What conclusions can we draw from experience? How can we test them? What evidence do we need to prove a new idea is correct?

The next step is to change our mental models. Break apart paradigms. Question where conventions came from. Pivot and make reassessments if necessary.

Problem-solving isn’t a linear process. We can’t make one decision and then sit back and await success.

Argyris found that many professionals are skilled at teaching others, yet find it difficult to recognize the problems they themselves cause (see Galilean Relativity). It’s easy to focus on other people; it’s much harder to look inward and face complex challenges. Doing so brings up guilt, embarrassment, and defensiveness. As John Grey put it, “If there is anything unique about the human animal, it is that it has the ability to grow knowledge at an accelerating rate while being chronically incapable of learning from experience.”

When we repeat a single loop process, it becomes a habit. Each repetition requires less and less effort. We stop questioning or reconsidering it, especially if it does the job (or appears to). While habits are essential in many areas of our lives, they don’t serve us well if we want to keep improving. For that, we need to push the single loop to the point of failure, to strengthen how we act in the double loop. It’s a bit like the Feynman technique — we have to dismantle what we know to see how solid it truly is.

“Fail early and get it all over with. If you learn to deal with failure... you can have a worthwhile career. You learn to breathe again when you embrace failure as a part of life, not as the determining moment of life.”

— Rev. William L. Swig

One example is the typical five-day, 9-to-5 work week. Most organizations stick to it year after year. They don’t reconsider the efficacy of a schedule designed for Industrial Revolution factory workers. This is single loop learning. It’s just the way things are done, but not necessarily the smartest way to do things.

The decisions made early on in an organization have the greatest long-term impact. Changing them in the months, years, or even decades that follow becomes a non-option. How to structure the work week is one such initial decision that becomes invisible. As G.K. Chesterton put it, “The things we see every day are the things we never see at all.” Sure, a 9-to-5 schedule might not be causing any obvious problems. The organization might be perfectly successful. But that doesn’t mean things cannot improve. It’s the equivalent of a child continuing to crawl because it gets them around. Why try walking if crawling does the job? Why look for another option if the current one is working?

A growing number of organizations are realizing that conventional work weeks might not be the most effective way to structure work time. They are using double loop learning to test other structures. Some organizations are trying shorter work days or four-day work weeks or allowing people to set their own schedules. Managers then keep track of how the tested structures affect productivity and profits. Over time, it becomes apparent whether the new schedule is better than the old one.

37Signals is one company using double loop learning to restructure their work week. CEO Jason Fried began experimenting a few years ago. He tried out a four-day, 32-hour work week. He gave employees the whole of June off to explore new ideas. He cut back on meetings and created quiet spaces for focused work. Rather than following conventions, 37Signals became a laboratory looking for ways of improving. Over time, what worked and what didn't became obvious.

Double loop learning is about data-backed experimentation, not aimless tinkering. If a new idea doesn't work, it's time to try something else.

In an op-ed for *The New York Times*, Camille Sweeney and Josh Gosfield give the example of David Chang. Double loop learning turned his failing noodle bar into an award-winning empire.

After apprenticing as a cook in Japan, Mr. Chang started his own restaurant. Yet his early efforts were ineffective. He found himself overworked and struggling to make money. He knew his cooking was excellent, so how could he make it profitable? Many people would have quit or continued making irrelevant tweaks until the whole endeavor failed. Instead, Mr. Chang shifted from single to double loop learning. A process of making honest self-assessments began. One of his foundational beliefs was that the restaurant should serve only noodles, but he decided to change the menu to reflect his skills. In time, it paid off; "the crowds came, rave reviews piled up, awards followed and unimaginable opportunities presented themselves." This is what double loop learning looks like in action: questioning everything and starting from scratch if necessary.

Josh Waitzkin's approach (as explained in *The Art of Learning*) is similar. After reaching the heights of competitive chess, Waitzkin turned his focus to martial arts. He began with tai chi chuan. Martial arts and chess are, on the surface, completely different, but Waitzkin used double loop learning for both. He progressed quickly because he was willing to lose matches if doing so meant he could learn. He noticed that other martial arts students had a tendency to repeat their mistakes, letting fruitless habits become ingrained. Like the managers Argyris worked with, students grew defensive when challenged. They wanted to be right, even if it prevented their learning. In contrast, Waitzkin viewed practice as an experiment. Each session was an opportunity to test his beliefs. He mastered several martial arts, earning a black belt in jujitsu and winning a world championship in tai ji tui shou.

Argyris found that organizations learn best when people know how to communicate. (No surprise there.) Leaders need to listen actively and open up exploratory dialogues so that problematic assumptions and conventions can be revealed. Argyris identified some key questions to consider.

- What is the current theory in use?
- How does it differ from proposed strategies and goals?
- What unspoken rules are being followed, and are they detrimental?
- What could change, and how?
- Forget the details; what's the bigger picture?

Meaningful learning doesn't happen without focused effort. Double loop learning is the key to turning experience into improvements, information into action, and conversations into progress.

47. The Power of Questions

The quality of the answers we get are directly correlated with the quality of the questions we ask. Here's how to improve your questions.

When we run our once-a-year Re:Think Europe event, 10 participants work with us for a month before the event to hone their questions. This is the most intense event we run for a reason. Each person brings a problem or challenge to the table for others to help with. Participants research each other's problems before the event. Before they even show up, refining and iterating the questions often help the participants make huge leaps forward. As a society, we tend to focus a lot on answers. Answers are solutions to problems. We tend to give less prestige to questions. Everyone has them. They're easy. It's the answers that take the work.

This overlooks the power of questions. Asking questions gives you a better understanding of everything: the situation you are in, the challenges you are facing. Life.

Let me share a story that took place in my second-year history class at university. We started discussing the assigned reading. I didn't really understand it, but I figured I'd get it just sitting there. Then this guy raised his hand and said, "Hey Professor, could you explain [technical term]? It wasn't clear to me from the article."

Boom. I had this startling insight. Up until then, I had always been afraid to ask questions like that for fear of looking stupid [read about pluralistic ignorance here]. But this guy didn't appear stupid. At that moment, he seemed like the smartest guy in the class.

Asking questions means you want to learn. You want to understand and know. So where do you start? Anywhere you want. But don't feel pressure to begin with the big questions, the ones we all confront at one time or another, like the meaning of life, or what exists beyond our physical experience of earth. There is a significant amount to be learned from the seemingly mundane ones, questions that seem so basic, once we reach about age 12 we no longer bother asking them—because we either think we know the answer or are afraid of admitting we don't.

Consider the following three questions:

1. What is a horse?
2. What is green?
3. What is a point in time?

At first glance, these don't seem difficult. They're grade school stuff. But these are actually really hard questions that can show us how much is to be gained from asking them.

First, what is a horse? Most people will list the physical characteristics that horses have in common, saying, "A horse has four legs, and a mane, and you can ride it." This is definitely true of some horses, but we would reasonably consider a three-legged horse still a horse. And a horse doesn't cease to be a horse if it can't be ridden. It doesn't become some other animal.

There is, I think, some component of DNA that is the same for all horses, a bit of code that tells the cells to form the horse. So why don't we reference a specific gene sequence when we are explaining what a horse is? Because it wouldn't in any way communicate what we mean by the word horse. Horses have properties that relate to our experience of them. The problem is, they all don't have the same properties.

So what we do is fix a vague concept in our minds of horseness. It can't be an image, because then it would be a specific horse, and it can't be explicitly defined because we wouldn't encompass the whole category. So we keep it at a fuzzy level that, despite its lack of precision, is extremely useful when we have to communicate in any way about horses. The abstract concept must stay abstract to retain its utility.

So, are you being pedantic when you ask, “What is a horse?” Not at all. You’re actually doing something very important. You are assessing the understanding of the person you are talking to about yours. And you discover that it’s never going to be a perfect match. As for the second question, what is green? This one is definitely more painful. The easy answer is a color. But that’s not a good answer, for what is a color? A quality that objects possess? Ooh cool. Where can I get some of this quality? Ah. Nowhere. Green is a quality that does not exist outside of the objects that possess it.

There is no place you can see green without seeing something being green. How unfair is this? I know green. I see it all the time. But it is not a thing I can hold. A change in the way my eyes process light and there could cease to be green [related: [How do you know that you know what you know?](#)]. But greenness would always be out there, a property of the interaction of light and molecules that can be so vivid but doesn’t actually exist on its own. Does this make asking, “What is green?” a waste of time? No. Wanting to get a handle on the fundamentals is never a waste of time. You can learn what you can influence and what you cannot. In this case you learn that you can change the color of an object, but you have no powers when it comes to color itself.

Finally, what is a point in time? This one really hurts. First, we should ask what is a point? Conveniently, [Euclid provided some definitions](#) over 2000 years ago.

1. A point is that which has no part.
2. A line is length without breadth.
3. A surface is that which has length and breadth only.

From this, we can conclude that a point has neither length nor breadth. That’s okay. It’s just this thing, and if you connect two of them with length you get a line. Euclid also said, “The extremities of lines are points.” It all works. Conceptually, it makes sense. I can wrap my head around it enough to do basic geometry. Great.

But if you actually think about it, your brain could explode. A point has neither length nor breadth? Then what does it have? It has to have something, to be something, doesn’t it? But anything that occupies space must have length and breadth, however infinitesimal. Since points have neither, they cannot occupy space. But then how can they form the ends of lines? How can they be?

The same thing happens when we try to conceive of a point in time. It’s something we all get. We say things like “going forward” as if there is a specific moment that we can measure all other moments against. But how exactly would you describe a moment in time? To say that implies that there are many moments, all of which could be distinguished from each other. But can they be? What fills the space between them? And if you say nothing, then how can the points be distinguished at all?

Are we unreasonable, then, when we question, “What is a point in time?” No. We can’t question everything every day, as it would likely put us in a state of paralysis, but asking questions like this shows that there is much to be gained from the act of trying to answer. We can learn a lot, often more, from work involved in answering a question than from the answer itself.

There are no dumb questions. Don’t be afraid to ask them. They are the most straight forward path to learning.

Article Summary

- Good questions are the key to better insights.
- Questions allow you to assess your understanding as well as others. Identifying gaps in your knowledge is the first step to filling them.

- We can learn a lot, often more, from the work involved in answering a question than from the answer itself.

48. Learning by Thinking: How Reflection Aids Performance

“By three methods we may learn wisdom: First, by reflection, which is noblest; Second, by imitation, which is easiest; and third, by experience, which is the bitterest.”

— Confucius

It's been a while since I covered an academic paper. But one by Giada Di Stefano, Francesca Gino, Gary Pisano, and Bradley Staats on the role reflection plays in learning is fascinating.

Learning plays an important role in everything. This is why the concept of learning has gotten a lot of attention from scholars. You can argue that today's "Knowledge economy" further accelerates the pace of learning; things are changing and we need to keep up. This, the authors argue, makes our experience more productive and builds our confidence "in the ability to achieve a goal," which further translates into "higher rates of learning."

What is learning?

"Learning," they write, "is defined as a lasting change in knowledge generated by experience."

(There are) two types of learning, which are based on the source of such experience: direct learning from one's own experience and indirect learning from the experience of others.

Most research tends to focus on "learning by doing" whereas Farnam Street is more oriented towards indirect learning.

In Learning by Thinking: How Reflection Aids Performance the authors "take a less traveled road and focus on how individual learning can be augmented when individuals can not only "do" but also "think" about what they have been doing." That is, we learn better when we couple learning by doing with reflection — "that is, the intentional attempt to synthesize, abstract, and articulate the key lessons taught by experience."

This, the authors argue, makes our experience more productive and builds our confidence "in the ability to achieve a goal," which further translates into "higher rates of learning."

Dual Process Theory

The argument is based on the dual-process theory, which suggests:

"... the existence of two systems of thought that underlie intuitive and reflective processing, often referred to as type 1 and type 2, respectively ... We propose a dual-process learning model in which the automatic, unconscious process of learning generated from experience is coupled with the controlled, conscious attempt at learning."

Findings

Our findings suggest that reflection is a powerful mechanism by which experience is translated into learning. In particular, we find that individuals perform significantly better on subsequent tasks when they think about what they learned from the task they completed. Interestingly, we do not observe an additional boost in performance when individuals share the insights from their reflection efforts with others. Results of mediation analyses further show that the improvement in performance observed when individuals are learning by thinking is explained by increased self-efficacy generated by reflection.

Interesting, my system for remembering what I read has intuitive roots built around reflection.

General Discussion

Though some organizations are increasingly relying on some group reflection (e.g., "after-action reports"), there has been almost no effort to encourage individuals to reflect, and people often fail to engage in self-reflection themselves. Though reflection entails the high opportunity cost of one's time, we argue and show that reflecting after completing tasks is no idle pursuit: it can powerfully enhance the learning process. Learning, we find, can be augmented if one deliberately focuses on thinking about what one has been doing. In

addition to showing a significant performance differential when comparing learning-by-doing alone to learning-by-doing coupled with reflection, we also demonstrate that the effect of reflection on learning is mediated by greater self-efficacy.

This part was also interesting. What matters is reflection, not why you are reflecting. Across our studies, we also included a condition in which people shared their reflections with others. Interestingly, our results show that while sharing one's learning improves one's subsequent performance, the value of sharing is no different than that of reflecting and keeping one's thoughts to oneself.

Implications

The implications here support much that we've already covered on Farnam Street.

"... taking time away from training and reallocating that time to reflection actually improved individual performance."

Learning and decision journals encourage reflection and thus knowledge.

Companies often use tools such as learning journals as a way to encourage reflection in training and regular operations.

It's all about smarter, not harder.

"Our personal experience is that individuals of all ages may not treat these exercises with much seriousness."

So if you want a leg up, pay attention and take this seriously.

49. The Illusory Truth Effect: Why We Believe Fake News, Conspiracy Theories and Propaganda

When a “fact” tastes good and is repeated enough, we tend to believe it, no matter how false it may be. Understanding the illusory truth effect can keep us from being bamboozled.

A recent *Verge* article looked at some of the unsavory aspects of working as Facebook content moderators—the people who spend their days cleaning up the social network’s most toxic content. One strange detail stands out. The moderators the *Verge* spoke to reported that they and their coworkers often found themselves believing fringe, often hatemongering conspiracy theories they would have dismissed under normal circumstances. Others described experiencing paranoid thoughts and intense fears for their safety.

An overnight switch from skepticism to fervent belief in conspiracy theories is not unique to content moderators. In a *Nieman Lab* article by Laura Hazard Owen, she explains that researchers who study the spread of disinformation online can find themselves struggling to be sure about their own beliefs and needing to make an active effort to counteract what they see. Some of the most fervent, passionate conspiracy theorists admit that they first fell into the rabbit hole when they tried to debunk the beliefs they now hold. There’s an explanation for why this happens: the illusory truth effect.

The illusory truth effect

“Facts do not cease to exist because they are ignored.”

— *Aldous Huxley*

Not everything we believe is true. We may act like it is and it may be uncomfortable to think otherwise, but it’s inevitable that we all hold a substantial number of beliefs that aren’t objectively true. It’s not about opinions or different perspectives. We can pick up false beliefs for the simple reason that we’ve heard them a lot.

If I say that the moon is made of cheese, no one reading this is going to believe that, no matter how many times I repeat it. That statement is too ludicrous. But what about something a little more plausible? What if I said that moon rock has the same density as cheddar cheese? And what if I wasn’t the only one saying it? What if you’d also seen a tweet touting this amazing factoid, perhaps also heard it from a friend at some point, and read it in a blog post?

Unless you’re a geologist, a lunar fanatic, or otherwise in possession of an unusually good radar for moon rock-related misinformation, there is a not insignificant chance you would end up believing a made-up fact like that, without thinking to verify it. You might repeat it to others or share it online. This is how the illusory truth effect works: we all have a tendency to believe something is true after being exposed to it multiple times. The more times we’ve heard something, the truer it seems. The effect is so powerful that repetition can persuade us to believe information we know is false in the first place. Ever thought a product was stupid but somehow you ended up buying it on a regular basis? Or you thought that new manager was okay, but now you participate in gossip about her?

The illusory truth effect is the reason why advertising works and why propaganda is one of the most powerful tools for controlling how people think. It’s why the speech of politicians can be bizarre and multiple-choice tests can cause students problems later on. It’s why fake news spreads and retractions of misinformation don’t work. In this post, we’re going to look at how the illusory truth effect works, how it shapes our perception of the world, and how we can avoid it.

The discovery of the illusory truth effect

“Rather than love, than money, than fame, give me truth.”

— *Henry David Thoreau*

The illusory truth effect was first described in a 1977 paper entitled “Frequency and the Conference of Referential Validity,” by Lynn Hasher and David Goldstein of Temple University and Thomas Toppino of Villanova University. In the study, the researchers presented a group of students with 60 statements and asked them to rate how certain they were that each was either true or false. The statements came from a range of subjects and were all intended to be not too obscure, but unlikely to be familiar to study participants. Each statement was objective—it could be verified as either correct or incorrect and was not a matter of opinion. For example, “the largest museum in the world is the Louvre in Paris” was true.

Students rated their certainty three times, with two weeks in between evaluations. Some of the statements were repeated each time, while others were not. With each repetition, students became surer of their certainty regarding the statements they labelled as true. It seemed that they were using familiarity as a gauge for how confident they were of their beliefs.

An important detail is that the researchers did not repeat the first and last 10 items on each list. They felt students would be most likely to remember these and be able to research them before the next round of the study. While the study was not conclusive evidence of the existence of the illusory truth effect, subsequent research has confirmed its findings.

Why the illusory truth effect happens

“The sad truth is the truth is sad.”

— *Lemony Snicket*

Why does repetition of a fact make us more likely to believe it, and to be more certain of that belief? As with other cognitive shortcuts, the typical explanation is that it’s a way our brains save energy. Thinking is hard work—remember that the human brain uses up about 20% of an individual’s energy, despite accounting for just 2% of their body weight.

The illusory truth effect comes down to processing fluency. When a thought is easier to process, it requires our brains to use less energy, which leads us to prefer it. The students in Hasher’s original study recognized the repeated statements, even if not consciously.

That means that processing them was easier for their brains.

Processing fluency seems to have a wide impact on our perception of truthfulness. Rolf Reber and Norbert Schwarz, in their article “Effects of Perceptual Fluency on Judgments of Truth,” found that statements presented in an easy-to-read color are judged as more likely to be true than ones presented in a less legible way. In their article “Birds of a Feather Flock Conjointly (?): Rhyme as Reason in Aphorisms,” Matthew S. McGlone and Jessica Tofighbakhsh found that aphorisms that rhyme (like “what sobriety conceals, alcohol reveals”), even if someone hasn’t heard them before, seem more accurate than non-rhyming versions. Once again, they’re easier to process.

Fake news

“One of the saddest lessons of history is this: If we’ve been bamboozled long enough, we tend to reject any evidence of the bamboozle. We’re no longer interested in finding out the truth. The bamboozle has captured us. It’s simply too painful to acknowledge, even to ourselves, that we’ve been taken.”

— Carl Sagan

The illusory truth effect is one factor in why fabricated news stories sometimes gain traction and have a wide impact. When this happens, our knee-jerk reaction can be to assume that anyone who believes fake news must be unusually gullible or outright stupid. Evan Davis writes in *Post Truth*, “Never before has there been a stronger sense that fellow citizens have been duped and that we are all suffering the consequences of their

intellectual vulnerability.” As Davis goes on to write, this assumption isn’t helpful for anyone. We can’t begin to understand why people believe seemingly ludicrous news stories until we consider some of the psychological reasons why this might happen. Fake news falls under the umbrella of “information pollution,” which also includes news items that misrepresent information, take it out of context, parody it, fail to check facts or do background research, or take claims from unreliable sources at face value. Some of this news gets published on otherwise credible, well-respected news sites due to simple oversight. Some goes on parody sites that never purport to tell the truth, yet are occasionally mistaken for serious reporting. Some shows up on sites that replicate the look and feel of credible sources, using similar web design and web addresses. And some fake news comes from sites dedicated entirely to spreading misinformation, without any pretense of being anything else.

A lot of information pollution falls somewhere in between the extremes that tend to get the most attention. It’s the result of people being overworked or in a hurry and unable to do the due diligence that reliable journalism requires. It’s what happens when we hastily tweet something or mention it in a blog post and don’t realize it’s not quite true. It extends to miscited quotes, doctored photographs, fiction books masquerading as memoirs, or misleading statistics.

The signal to noise ratio is so skewed that we have a hard time figuring out what to pay attention to and what we should ignore. No one has time to verify everything they read online. No one. (And no, offline media certainly isn’t perfect either.) Our information processing capabilities are not infinite and the more we consume, the harder it becomes to assess its value.

Moreover, we’re often far outside our circle of competence, reading about topics we don’t have the expertise in to assess accuracy in any meaningful way. This drip-drip of information pollution is not harmless. Like air pollution, it builds up over time and the more we’re exposed to it, the more likely we are to end up picking up false beliefs which are then hard to shift. For instance, a lot of people believe that crime, especially the violent kind, is on an upward trend year by year—in a 2016 study by Pew Research, 57% of Americans believed crime had worsened since 2008. This despite violent crime having actually fallen by nearly a fifth during that time. This false belief may stem from the fact that violent crime receives a disproportional amount of media coverage, giving it wide and repeated exposure.

When people are asked to rate the apparent truthfulness of news stories, they score ones they have read multiple times more truthful than those they haven’t. Danielle C. Polage, in her article “Making Up History: False Memories of Fake News Stories,” explains that a false story someone has been exposed to more than once can seem more credible than a true one they’re seeing for the first time. In experimental settings, people also misattribute their previous exposure to stories, believing they read a news item from another source when they actually saw it as part of a prior part of a study. Even when people *know* the story is part of the experiment, they sometimes think they’ve also read it elsewhere. The repetition is all that matters.

Given enough exposure to contradictory information, there is almost no knowledge that we won’t question.

Propaganda

“If a lie is only printed often enough, it becomes a quasi-truth, and if such a truth is repeated often enough, it becomes an article of belief, a dogma, and men will die for it.”

— *Isa Blagden*

Propaganda and fake news are similar. By relying on repetition, disseminators of propaganda can change the beliefs and values of people.

Propaganda has a lot in common with advertising, except instead of selling a product or service, it's about convincing people of the validity of a particular cause. Propaganda isn't necessarily malicious; sometimes the cause is improved public health or boosting patriotism to encourage military enrollment. But often propaganda is used to undermine political processes to further narrow, radical, and aggressive agendas.

During World War II, the graphic designer Abraham Games served as the official war artist for the British government. Games's work is iconic and era-defining for its punchy, brightly colored visual style. His army recruitment posters would often feature a single figure rendered in a proud, strong, admirable pose with a mere few words of text. They conveyed to anyone who saw them the sorts of positive qualities they would supposedly gain through military service. Whether this was true or not was another matter. Through repeated exposure to the poster, Games instilled the image the army wanted to create in the minds of viewers, affecting their beliefs and behaviors.

Today, propaganda is more likely to be a matter of quantity over quality. It's not about a few artistic posters. It's about saturating the intellectual landscape with content that supports a group's agenda. With so many demands on our attention, old techniques are too weak. Researchers Christopher Paul and Miriam Matthews at the Rand Corporation refer to the method of bombarding people with fabricated information as the "firehose of propaganda" model. While the report focuses on modern Russian propaganda, the techniques it describes are not confined to Russia. These techniques make use of the illusory truth effect, alongside other cognitive shortcuts. Firehose propaganda has four distinct features:

- High-volume and multi-channel
- Rapid, continuous and repetitive
- Makes no commitment to objective reality
- Makes no commitment to consistency

Firehose propaganda is predicated on exposing people to the same messages as frequently as possible. It involves a large volume of content, repeated again and again across numerous channels: news sites, videos, radio, social media, television and so on. These days, as the report describes, this can also include internet users who are paid to repeatedly post in forums, chat rooms, comment sections and on social media disputing legitimate information and spreading misinformation. It is the sheer volume that succeeds in obliterating the truth. Research into the illusory truth effect suggests that we are further persuaded by information heard from multiple sources, hence the efficacy of funneling propaganda through a range of channels.

Seeing as repetition leads to belief in many cases, firehose propaganda doesn't need to pay attention to the truth or even to be consistent. A source doesn't need to be credible for us to end up believing its messages. Fact-checking is of little help because it further adds to the repetition, yet we feel compelled not to ignore obviously untrue propagandistic material.

Firehose propaganda does more than spread fake news. It nudges us towards feelings like paranoia, mistrust, suspicion, and contempt for expertise. All of this makes future propaganda more effective. Unlike those espousing the truth, propagandists can move fast because they're making up some or all of what they claim, meaning they gain a foothold in our minds first. First impressions are powerful. Familiarity breeds trust.

How to combat the illusory truth effect

So how can we protect ourselves from believing false news and being manipulated by propaganda due to the illusory truth effect? The best route is to be far more selective. The information we consume is like the food we eat. If it's junk, our thinking will reflect that.

We don't need to spend as much time reading the news as most of us do. As with many other things in life, more can be less. The vast majority of the news we read is just information pollution. It doesn't do us any good.

One of the best solutions is to quit the news. This frees up time and energy to engage with timeless wisdom that will improve your life. Try it for a couple of weeks. And if you aren't convinced, read a few days' worth of newspapers from 1978. You'll see how much the news doesn't really matter at all.

If you can't quit the news habit, stick to reliable, well-known news sources that have a reputation to uphold. Steer clear of dubious sources whenever you can—even if you treat it as entertainment, you might still end up absorbing it. Research unfamiliar sources before trusting them. Be cautious of sites that are funded entirely by advertising (or that pay their journalists based on views) and seek to support reader-funded news sources you get value from if possible. Prioritize sites that treat their journalists well and don't expect them to churn out dozens of thoughtless articles per day. Don't rely on news in social media posts without sources, from people outside of their circle of competence.

Avoid treating the news as entertainment to passively consume on the bus or while waiting in line. Be mindful about it—if you want to inform yourself on a topic, set aside designated time to learn about it from multiple trustworthy sources. Don't assume breaking news is better, as it can take some time for the full details of a story to come out and people may be quick to fill in the gaps with misinformation. Accept that you can't be informed about everything and most of it isn't important. Pay attention to when news items make you feel outrage or other strong emotions, because this may be a sign of manipulation. Be aware that correcting false information can further fuel the illusory truth effect by adding to the repetition.

We can't stop the illusory truth effect from existing. But we can recognize that it is a reality and seek to prevent ourselves from succumbing to it in the first place.

Conclusion

Our memories are imperfect. We are easily led astray by the illusory truth effect, which can direct what we believe and even change our understanding of the past. It's not about intelligence—this happens to all of us. This effect is too powerful for us to override it simply by learning the truth. Cognitively, there is no distinction between a genuine memory and a false one. Our brains are designed to save energy and it's crucial we accept that.

We can't just pull back and think the illusory truth only applies to other people. It applies to everyone. We're all responsible for our own beliefs. We can't pin the blame on the media or social media algorithms or whatever else. When we put effort into thinking about and questioning the information we're exposed to, we're less vulnerable to the illusory truth effect. Knowing about the effect is the best way to identify when it's distorting our worldview. Before we use information as the basis for important decisions, it's a good idea to verify if it's true, or if it's something we've just heard a lot.

Truth is a precarious thing, not because it doesn't objectively exist, but because the incentives to warp it can be so strong. It's up to each of us to seek it out.

50. The Feynman Learning Technique

The Feynman Technique is the best way to supercharge your learning. And it works no matter the subject. Devised by Nobel Prize-winning physicist Richard Feynman, it leverages the power of teaching for better learning.

Learning doesn't happen from skimming through a book or remembering enough to pass a test.

Information is learned when you can explain it and use it in a wide variety of situations.

The Feynman Technique gets more mileage from the ideas you encounter instead of rendering anything new into isolated, useless factoids.

When you really learn something, you give yourself a tool to use for the rest of your life.

The more you know, the fewer surprises you will encounter because most new things will connect to something you already understand.

Ultimately, the point of learning is to understand the world. But most of us don't bother to deliberately learn anything.

We memorize what we need to as we move through school, then forget most of it. As we continue through life, we don't extrapolate from our experiences to broaden the applicability of our knowledge. Consequently, life kicks us in the ass time and again.

To avoid the pain of being bewildered by the unexpected, the Feynman Technique helps you turn information into knowledge that you can access as easily as reaching for a chair.

*

The Feynman Technique

"Any intelligent fool can make things bigger, more complex, and more violent. It takes a touch of genius—and a lot of courage—to move in the opposite direction."

E.F. Schumacher

There are four steps to the Feynman Learning Technique, based on the method Richard Feynman originally used. We have adapted it slightly after reflecting on our own experiences using this process to learn. The steps are as follows:

1. Pretend to teach a concept you want to learn about to a student in the sixth grade.
2. Identify gaps in your explanation. Go back to the source material to better understand it.
3. Organize and simplify.
4. Transmit (optional).

Step 1: Pretend to teach it to a child

Take out a blank sheet of paper. At the top, write the subject you want to master. Now write out everything you know about the subject as if you were teaching it to a child or a rubber duck sitting on your desk.

It's important to remember that you are not teaching to your smart adult friend, but rather a child who has just enough vocabulary and attention span to understand basic concepts and relationships. It has to be simple and clear. There is nowhere to hide in obfuscation.

Or, for a different angle on the Feynman Technique, you could place a rubber duck on your desk and try explaining the concept to it. Software engineers sometimes tackle debugging by explaining their code, line by line, to a rubber duck. It sounds silly, but it's a forcing function to make you walk through your thinking as simply as possible.

It turns out that one of the ways we mask our lack of understanding is by using complicated vocabulary and jargon. The truth is, if you can't clearly and simply define the words and terms you are using, you don't really know what you're talking about.

If you look at a painting and describe it as "abstract" because that's what you heard in art class, you demonstrate no understanding. You're just mimicking what you've heard. You haven't learned anything.

When you write out an idea from start to finish in simple language that a child can understand, you force yourself to understand the concept at a deeper level and simplify relationships and connections between ideas. You can better explain the why behind your description of the what.

Writing helps you think because it gives you nowhere to hide.

Looking at the painting again, you will be able to say that the painting doesn't display buildings like the ones we look at every day. Instead, it uses certain shapes and colors to depict a city landscape. You will be able to point out what these are. You will be able to engage in speculation about why the artist chose those shapes and those colors. You will be able to explain why artists sometimes do this, and you will be able to communicate what you think of the piece considering all of this.

Chances are, after capturing a full explanation of the painting in the simplest possible terms that would be easily understood by a sixth-grader, you will have learned a lot about that painting and abstract art in general.

Some of capturing what you would teach will be easy. These are the places where you have a clear understanding of the subject. But you will find many places where things are much foggy.

Step 2: Identify gaps in your explanation

Areas, where you struggle in Step 1, are the points where you have some gaps in your understanding.

Identifying gaps in your knowledge—where you forget something important, aren't able to explain it, or simply have trouble thinking of how variables interact—is a critical part of the learning process.

Filling those gaps is when you really make the learning stick.

Now that you know where you have gaps in your understanding go back to the source material. Augment it with other sources. Look up definitions. Keep going until you can explain everything you need to in basic terms.

Only when you can explain your understanding without jargon and in simple terms can you demonstrate understanding. Think about it this way. If you require complicated terminology to explain what you know, you have no flexibility. When someone asks you a question, you can only repeat what you've already said.

Simple terms can be rearranged and easily combined with other words to communicate your point. When you can say something in multiple ways using different words, you understand it really well.

Being able to explain something in a simple, accessible way shows you've done the work required to learn. Skipping it leads to the illusion of knowledge—an illusion that can be quickly shattered when challenged.

Identifying the boundaries of your understanding is also a way of defining your circle of competence. When you know what you know (and are honest about what you don't know), you limit the mistakes you're liable to make and increase your chance of success when applying knowledge.

Step 3. Organize and simplify

Now you have a set of hand-crafted notes containing a simple explanation. Organize them into a narrative that you can tell from beginning to end. Read it out loud. If the explanation sounds confusing at any point, go back to Step 2. Keep iterating until you have a story that you can tell to anyone who will listen.

If you follow this approach over and over, you will end up with a binder full of pages on different subjects. If you take some time twice a year to go through this binder, you will find just how much you retain.

Step 4: Transmit (optional)

This part is optional, but it's the logical result of everything you've just done.

If you really want to be sure of your understanding, run it past someone (ideally someone who knows little of the subject).

The ultimate test of your knowledge is your capacity to convey it to another. You can read out directly what you've written. You can present the material like a lecture. You can ask your friends for a few minutes of their time while you're buying them dinner. You can volunteer as a guest speaker in your child's classroom or your parents' retirement residence. All that really matters is that you attempt to transmit the material to at least one person who isn't that familiar with it.

The questions you get and the feedback you receive are invaluable for further developing your understanding.

Hearing what your audience is curious about will likely pique your own curiosity and set you on a path for further learning. After all, it's only when you begin to learn a few things really well do you appreciate how much there is to know.

The Feynman Technique is not only a wonderful recipe for learning but also a window into a different way of thinking that allows you to tear ideas apart and reconstruct them from the ground up. It also allows you to supercharge your learning from others.

Too often, we want to seem smart rather than learn. We nod along even when we don't understand what someone is talking about. This is a missed opportunity for learning. If you're having a conversation with someone and they start using jargon that you don't understand, ask them to explain it to you like you're twelve. Not only will you supercharge your own learning, but you'll also supercharge theirs.

Feynman's approach intuitively believes that intelligence is a process of growth, which dovetails nicely with the work of Carol Dweck, who describes the difference between a fixed and growth mindset.

"If you can't reduce a difficult engineering problem to just one 8-1/2 x 11-inch sheet of paper, you will probably never understand it."

—Ralph Peck

What does it mean to "know?"

Richard Feynman believed that *"the world is much more interesting than any one discipline."* He understood the difference between knowing something and knowing the name of something, as well as how, when you truly know something, you can use that knowledge broadly.

When you only know what something is called, you have no real sense of what it is.

You can't take it apart and play with it or use it to make new connections and generate new insights. When you know something, the labels are unimportant because it's not necessary to keep it in the box it came in.

"The person who says he knows what he thinks but cannot express it usually does not know what he thinks."

—Mortimer Adler

Feynman's explanations—on why questions, why trains stay on the tracks as they go around a curve, how we look for new laws of science, or how rubber bands work—are simple and powerful. He doesn't hide behind abstraction or jargon.

Here he articulates the difference between knowing the name of something and understanding it.

"See that bird? It's a brown-throated thrush, but in Germany it's called a halzenfugel, and in Chinese they call it a chung ling, and even if you know all those names for it, you still know nothing about the bird. You only know something about people: what they call the bird. Now that thrush sings, and teaches its young to fly, and flies so many miles away during the summer across the country, and nobody knows how it finds its way."

Knowing the name of something doesn't mean you understand it. We talk in fact-deficient, obfuscating generalities to cover up our lack of understanding.

51. What Information Do You Need in Order to Change?

“Feedback is an effective tool for promoting efficient behavior: it enhances individuals’ awareness of choice consequences in complex settings.” —“Feedback and Efficient Behavior,” Sandro Casal, Nives DellaValle, Luigi Mittone, and Ivan Soraperra

We all want to improve at something. Skills we’d like to develop, habits we like to change, relationships we’d like to improve—there are lots of areas where we’d love to see positive, meaningful change.

Sometimes though, we don’t know how to keep moving forward.

We do research. We think of strategies. We try to implement a few tactics. And then we get stuck because we aren’t sure if what we’re doing is moving us in the right direction. So we keep on spinning our wheels, running without getting anywhere.

When you’re stuck, you need feedback. Feedback is a valuable source of information that you can use to effect the changes you want. You need information that tells you what you’re doing well and where you’re going wrong. Then you can use that information to plan tactics for bridging the gap between where you are now and where you want to be.

The more feedback you can get, the better. But how do you get good feedback?

Sometimes feedback is obvious, like when someone laughs at one of our jokes. They found it funny, and their reaction emboldens us to later try the joke on someone else.

Sometimes feedback is codified into our professional lives, such as during a formal performance review.

Often though, if we want feedback we have to actively seek it out.

How feedback works in behavior change

“A robust finding in economics, psychology, and behavioral sciences is the systematic failure to act according to rational well-informed preferences. This failure to rationally process and integrate information due to limited cognitive resources may lead to inefficient behavior in many domains of everyday life and may produce costs that, in some cases, can be avoided simply by highlighting the consequences of such behavior.” —“Feedback and Efficient Behavior,” Sandro Casal, Nives DellaValle, Luigi Mittone, and Ivan Soraperra

A really simple example of the effect of feedback on behavioral change is energy consumption. Most people don’t have a deep understanding of their energy usage. In your home, do you use more or less energy than your neighbors? What’s your consumption like compared to the national average? The global average? What activities and habits use the most energy? Studies show that feedback on usage can be used quickly by consumers to make lasting change.

If you decide you want to reduce your energy consumption, research on how to do it is a great place to start. But feedback on the impacts of your subsequent choices is equally important.

Energy companies have started providing consumers with detailed information on their consumption, such as amount used in comparable months, what in the home is using the most energy, and usage according to time of day. Some companies go further by relating energy consumption to local and global effects, like brownouts and light pollution. People can then further adjust their behavior by switching appliances or better insulating their home, and they can stay motivated to stick to the new behavior because of the consistent feedback.

Having direct feedback on the results of your specific actions can reinforce positive changes, help you develop habits, and inspire you to take further action. Feedback also helps you set goals for what you can reasonably accomplish.

Trying to make ongoing systemic changes in life without feedback on those changes is hard. Feedback gives you the information you need to improve. Without it, you may be completely missing the mark of what you want to achieve.

Don't be afraid to ask for feedback

Asking how you could be a better partner, team member, friend, or leader from the people best placed to give you accurate feedback is a requirement for improving. If your actions are eventually going to get you fired, divorced, or ghosted by your close friends, you probably want feedback communicating the steps you're taking toward disaster. Getting useful information in an ongoing, iterative loop gives you the opportunity to discuss solutions and make changes.

Feedback is baked into some professions. Writers have editors. Athletes have coaches. Actors have directors. In a *New York Times* [article](#) about the television show *The Good Place*, the show's creator, Michael Schur, says of actor Kristen Bell, "*She just has a really low center of gravity for how she approaches her job; you can give her forty notes on a line, and she'll go, 'Yep, got it,' and she'll do all forty of those notes at once.*" When you trust the source, it's easier to accept and incorporate feedback.

If you aren't getting enough feedback or you want to augment what feedback you routinely get, hire a coach—an expert who knows how to give useful feedback in the area you want to improve in. No one is so good at something that they have no room for improvement. We can all get better. And if you want to get better, you have to be open to the feedback you receive. You don't have to agree with it, but you do need to hear it. Getting defensive, critical, or shutting down will lead you to miss information and prevent others from attempting to give you feedback in the future.

If you want honest feedback, you have to prepare yourself to listen to things you might not want to hear. When you ask for feedback, explain that you're looking to identify your blind spots and that you're genuinely seeking information that will help you improve. Be as specific as you can. Be gracious with the results, even if they're unpleasant. Remember that [listening to a perspective doesn't mean you endorse it](#).

Of course, not all feedback is good. Sometimes it's just noise. Knowing when to ignore feedback that isn't useful or is badly intentioned can be just as useful as knowing when to seek out the kind of feedback that is instructive. For example, feedback and opinions are not the same thing. Feedback is based on observation and reactions to your specific actions. It does not aim to tell you what you *should* be doing; it simply seeks to enlarge your perspective on what you *are* doing. Opinions are just someone sharing how they feel about a particular aspect of the world – they have nothing to do with you in particular. The person giving you feedback is also indirectly sharing a wealth of information about themselves. Often what we give feedback on is related to what we find important, and what directly connects with our values.

The power of feedback

When you're aware of how powerful strong feedback can be, you may find you'd like to start giving more of it. When giving others feedback, ask yourself what information they might need to make meaningful change. [Giving great feedback](#) isn't about convincing others to do things your way. It's about giving them insight into how to improve on their own methods.

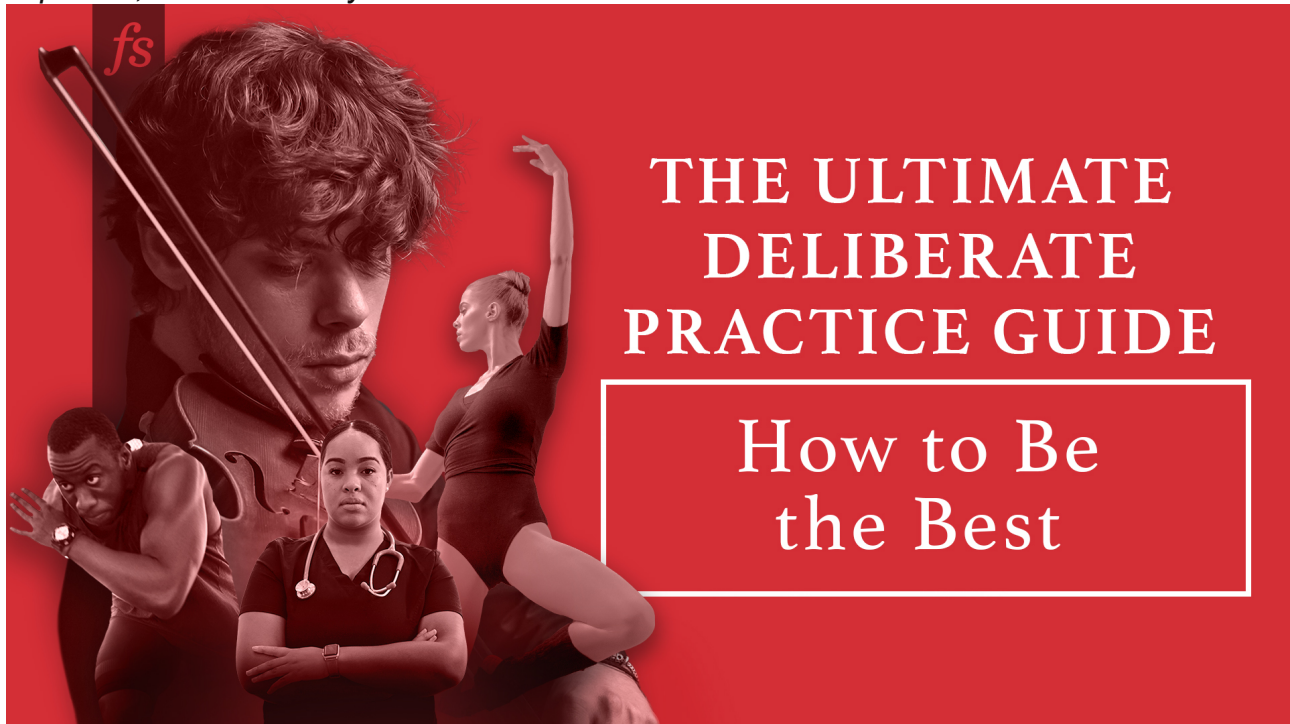

Giving good feedback requires an awareness of both what you're saying, and how you say it. To the first point, make it personal, provide specific examples, and notice how things have changed over time. Reassure the person that you are trying to help them be a better version of themselves, that you are in their corner. Consequently, be aware of your tone. You're a team member, not an accuser. And choose your timing wisely. At the end of a busy work day is probably not the time to give constructive feedback. People need the space to hear and process what you have to say.

We all want to get better at something. Don't underestimate the importance of feedback in helping you reach your goals.

52. The Ultimate Deliberate Practice Guide: How to Be the Best

Everything You Need to Know to Improve Your Performance at Anything—For Beginners and Experts

Deliberate practice is the best technique for achieving expert performance in every field—including writing, teaching, sports, programming, music, medicine, therapy, chess, and business. But there's much more to deliberate practice than 10,000 hours. Read this to learn how to accelerate your learning, overcome the "OK" plateau, turn experience into expertise, and enhance your focus.

What is deliberate practice?

*“Engaged in the creative process we feel more alive than ever, because we are making something and not merely consuming, masters of the small reality we create. In doing this work, we are in fact creating ourselves.” —Robert Greene, *Mastery**

Deliberate practice is what turns amateurs into professionals. Across every field, deliberate practice is what creates top performers and what they use to stay at the top of their game. It's absolutely essential for expert performance.

As a general concept, “practice” means preparing. It's the act of repeatedly performing certain activities with the intention of improving a specific associated skill. We rehearse what to do in low-pressure situations so we'll be better when we use a skill in situations where something is actually at stake, such as in a competition or in the workplace.

Although this definition may seem obvious, it's crucial to distinguish between doing something and practicing it, because they're not always synonymous.

The key distinction between doing and practicing is that we're only practicing something when we do it in a way that makes us better at it—or at least with that intention.

Deliberate practice means practicing with a clear awareness of the specific components of a skill we're aiming to improve and exactly how to improve them. Unlike regular practice, in which we work on a skill by repeating it again and again until it becomes almost mindless, deliberate practice is a laser-focused activity. It requires us to pay unwavering attention to what we're doing at any given moment and whether it's an improvement or not.

Geoff Colvin summarizes deliberate practice as such in *Talent Is Overrated*:

Deliberate practice is characterized by several elements, each worth examining. It is activity designed specifically to improve performance, often with a teacher's help; it can be repeated a lot; feedback on results is continuously available; it's highly demanding

mentally, whether the activity is purely intellectual, such as chess or business-related activities, or heavily physical, such as sports; and it isn't much fun.

The extraordinary power of deliberate practice is that it aims at constant progress. Practitioners are not content with repeating a skill at the same level. They have metrics for measuring their performance. And they aspire to see those metrics get continuously better. While engaging in deliberate practice, we are always looking for errors or areas of weakness. Once we identify one, we establish a plan for improving it. If one approach doesn't work, we keep trying new ones until something does.

Using deliberate practice, we can overcome many limitations that we might view as fixed. We can go further than we might even think possible when we begin. Deliberate practice creates new physical and mental capabilities—it doesn't just leverage existing ones. The more we engage in deliberate practice, the greater our capabilities become. Our minds and bodies are far more malleable than we usually realize.

Deliberate practice is a universal technique, and you can employ it for whatever you're trying to be the best (or just get a little bit better) at. It's easiest to apply to competitive fields with clear measurements and standards, including music, dance, football/soccer, cricket, hockey, basketball, golf, horse riding, swimming, and chess.

But deliberate practice is also invaluable for improving performance in fields such as teaching, nursing, surgery, therapy, programming, trading, and investing. It can even accelerate your progress in widely applicable skills such as writing, decision-making, leadership, studying, and spoken communication.

The key in any area is to identify objective standards for performance, study top performers, and then design practice activities reflecting what they do. Recent decades have seen dramatic leaps in what people are capable of doing in many fields. The explanation for this is that we're getting better at understanding and applying the principles of deliberate practice. As a field advances, people can learn from the best of what those who came before them figured out. The result is that now average high-schoolers achieve athletic feats and children advance to levels of musical prowess that would have seemed unthinkable a century earlier. And there's little evidence to suggest we've reached the limits of our physical or mental abilities in any area whatsoever.

Many of us spend a lot of time each week practicing different skills in our lives and work. But we don't automatically get better just because we repeat the same actions and behaviors, even if we spend hours per day doing it. Research suggests that in areas such as medicine, people with many years of experience are often no better than novices—and may even be worse.

If we want to improve a skill, we need to know *what* exactly has to change and what might get us there. Otherwise, we plateau.

Some people will tell you it's only possible for anyone to improve at anything through deliberate practice, and any other sort of practice is a waste of time. This is an exaggeration. In reality, regular practice works for reinforcing and maintaining skills. It can also help us improve skills, particularly in the early stages of learning something. However, deliberate practice *is* the only way to:

1. Reach expert-level performance and enjoy competitive success
2. Overcome plateaus in our skill level
3. Improve at a skill much faster than through regular practice

If you're just doing something for fun and don't care about constantly improving at it, you don't need deliberate practice. For example, maybe you like to go for a walk around a local park in the afternoons to clear your head. Although you're practicing that walk each time you go, you probably don't care about increasing your walking speed day by day. It's

enough that the repetitions further ingrain the habit and help maintain a certain level of physical fitness. Not everything in life is a competition! But if you want to keep getting better at something as fast as possible or reach an expert level, deliberate practice is vital. Another important point to note is that deliberate practice isn't just a catchy name we came up with out of thin air. The term is largely attributed to Karl Anders Ericsson, one of the most influential figures of all time in the field of performance psychology. It's something many scientists have studied for decades. Everything we say here is supported by substantial academic research, particularly Ericsson's work. We'll also debunk the numerous myths swirling around deliberate practice as a concept and reveal some of its significant limitations. So if you're looking for quick hacks for overnight success, you might want to look elsewhere. If you want a realistic roadmap for improving your performance, read on.

If we want to improve a skill,
we need to know what exactly
has to change and what
might get us there.

“

fs

The elements of deliberate practice

“Life is not always a matter of holding good cards, but sometimes, playing a poor hand well.” —Jack London

In this section, we'll break down the fundamental elements of deliberate practice and exactly how to incorporate them into your practice sessions. As Ericsson wrote in *Peak*, *“No matter what the field, the most effective approach to improving performance is to follow a single set of principles.”* We'll explain why each component is crucial and how they apply to different fields, and we'll cover multiple ways to implement them depending on your goals.

Deliberate practice is structured and methodical

“Everyone has talent. What's rare is the courage to follow it to the dark places where it leads.” —Erica Jong

As humans, we're wired to want to do the easiest thing at all times in order to conserve energy. Put more simply, it's in our nature to be lazy. When we practice something a lot, we develop habits that become almost effortless to enact. While that's beneficial in many areas of our lives (and helps us survive), it's something we have to overcome in order to engage in deliberate practice. We can't expect constant improvement if we keep repeating the elements of a skill we already know how to do with ease. That's only enough if we're just having fun or want to reinforce our habits.

Deliberate practice is structured to improve specific elements of a skill through defined techniques. Practitioners focus above all on what they *can't* do. They seek out areas of weaknesses impacting their overall performance, then target those. At every stage, they set tailored, measurable goals in order to gauge whether their practice is effective at moving them forwards. Numbers are a deliberate practitioner's best friend.

If you want to reach an expert level of performance, you need to begin practice sessions with a plan in mind. You need to know what you're working on, why, and how you intend to improve it. You also need a way to tell if your improvement efforts aren't working and if you need to try a new tactic. Once you reach your goal for that particular component of the skill, it's time to identify a new area of weakness to work on next.

Having lots of little, realistic goals with a game plan for achieving them makes deliberate practice motivating. There's a sense of ongoing movement, yet the next step is always a realistic stretch. Day by day, the gains from deliberate practice may feel modest. But when we look back over a longer period of time, small bits of progress compound into gigantic leaps.

How to implement this: Take the skill you're aiming to improve and break it down into the smallest possible component parts. Make a plan for working through them in a logical order, beginning with the fundamentals, then building upon them. Decide which parts you'd like to master over the next month. Put your practice sessions in your calendar, then plan precisely which parts of the skill you're going to work on during each session.

Don't expect your plan to be perfect. You'll likely need to keep modifying it as you discover new elements or unexpected weaknesses. The most important thing is to always go into practice with a plan for what you're working on and how. Knowing what you're doing next is the best way to stay on track and avoid aimless time-wasting. That means seeking to keep figuring out what separates you from the next level of performance so you can concentrate on that.

Deliberate practice is challenging and uncomfortable

"One must develop an instinct for what one can just barely achieve through one's greatest efforts." —Albert Einstein (attributed)

Imagine the world from the perspective of a baby learning to walk for the first time. It's not usually an easy process. They need to develop a lot of new skills and capabilities. They need to build enough muscular strength to stand upright without support. And they need to learn how to coordinate their limbs well enough to move around. Along the way, a baby needs to develop numerous sub-skills, such as how to grip supports to pull themselves up. It likely takes thousands of attempts to master walking—as well as numerous, falls, collisions, and other mishaps. We might not remember the process as adults, but a baby learning to walk needs to spend many hours challenging themselves and moving incrementally out of their comfort zone.

If we want to use deliberate practice, we could do with learning a thing or two from babies. Deliberate practice isn't necessarily fun while we're doing it. In fact, most of the time it's a process of repeated frustration and failure. We have to fall down a dozen times for every step we take. That's the whole point.

Seeing as deliberate practice requires us to keep targeting our weakest areas, it means spending time doing stuff we're not good at. In the moment, that can feel pretty miserable. But the quickest route to improvement involves stepping outside of our comfort zones.

The reason why people who have spent decades doing something are not necessarily better than newbies is that they're liable to get complacent and stop pushing themselves. We need to keep attempting to do things that feel out of reach at the moment.

In his studies of elite violinists, Ericsson asked them to rate different practice activities by how enjoyable they were and how much they contributed to improving performance.

Invariably, there was an inverse correlation between the usefulness of an activity and its enjoyability. As Ericsson puts it in *Peak*:

The reason that most people don't possess these extraordinary physical capabilities isn't because they don't have the capacity for them, but rather because they're satisfied to live in the comfortable rut of homeostasis and never do the work that is required to get out of it. They live in the world of "good enough." The same thing is true for all the mental activities we engage in.

Elsewhere in the book, he writes *"This is a fundamental truth about any sort of practice: If you never push yourself beyond your comfort zone, you will never improve."* The interesting part is the more time you spend deliberately practicing, the more comfortable you'll become with being uncomfortable.

Daniel Coyle writes in *The Little Book of Talent*:

There is a place, right on the edge of your ability, where you learn best and fastest. It's called the sweet spot. ... The underlying pattern is the same: Seek out ways to stretch yourself. Play on the edges of your competence. As Albert Einstein said, "One must develop an instinct for what one can just barely achieve through one's greatest efforts." The key word is 'barely.'

A quick way to assess if you're doing deliberate practice or just regular rote practice is to ask yourself if you ever feel bored or zone out during practice sessions. If the answer is yes, you're probably not practicing deliberately.

Deliberate practice isn't boring. Frustrating, yes. Maddening, yes. Annoying, even. But never boring. As soon as practicing a skill gets comfortable, it's time to up the stakes. Challenging yourself is about more than trying to work harder—it means doing new things. Pushing ourselves just beyond the limits of our abilities is uncomfortable, yet it's how we do our best—and indeed, it can be the source of some of our greatest moments of satisfaction. According to psychologist Mihaly Csikszentmihalyi, we often experience happiness as a result of entering a "flow" state, which occurs when we intensely focus on an activity that is challenging yet achievable. During moments of flow, we become so immersed in the activity that we lose any sense of time or of ourselves.

Noel Tichy, professor at the University of Michigan business school and the former chief of General Electric's famous management development center at Crotonville, puts the concept of practice into three zones: the comfort zone, the learning zone, and the panic zone.

Most of the time when we're practicing, we're really doing activities in our comfort zone. This doesn't help us improve because we can already do these activities easily. On the other hand, operating in the panic zone leaves us paralyzed, as the activities are too difficult and we don't know where to start. The only way to make progress is to operate in the learning zone, which are those activities that are just out of our reach.

Repetition inside the comfort zone does not equal deliberate practice. Deliberate practice requires that you operate in the learning zone and you repeat the activity a lot with feedback.

How to implement this: Each time you practice a component of a skill, aim to make it 10% harder than the level you find comfortable.

Once per month, have a practice session where you set yourself an incredibly ambitious stretch goal—not impossible, just well above your current level. Challenge yourself to see how close you can get to it. You might surprise yourself and find you perform far better than expected.

A common deliberate practice mistake is to plan a long practice session, then adjust the intensity of your practice to allow you to engage in a skill for the whole time. It's far more effective to engage in "sprints." Practice with the most intense focus you can manage for short periods of time, then take breaks. Seeing as you learn most when you stretch yourself beyond your current capabilities, shorter, more challenging practice periods are the way to go.

Deliberate practice requires rest and recovery time

“There is a time for many words, and there is also a time for sleep.” —Homer, The Odyssey

Seeing as deliberate practice is so challenging, it’s impossible to do it all day long. Across fields, top practitioners rarely spend more than around three to five hours per day on deliberate practice, at the high end. They may work for more hours than that per day, but few can sustain the mental energy to engage in deliberate practice for eight hours a day. Additional hours often result in diminishing negative returns, meaning more practice makes performance worse because it results in burnout. Geoff Colvin writes:

The work is so great that it seems no one can sustain it for very long. A finding that is remarkably consistent across disciplines is that four or five hours a day seems to be the upper limit of deliberate practice, and this is frequently accomplished in sessions lasting no more than an hour to ninety minutes.

Ericsson’s studies of elite violinists found they often took afternoon naps and slept an average of eight hours per night, considerably more than the average person. They were highly aware of the importance of sleep.

Even fitting in a single hour per day of deliberate practice is ample time to make substantial improvements, especially when we’re consistent with committing to it over the long haul. Continuous investments in success compound. In the long run, commitment pays off.

Not only do most deliberate practitioners not spend all day at it, they also devote a lot of time to recuperation and recovery. They sleep as much as their bodies need. They nap if necessary. They take frequent, refreshing breaks. Most of us understand that rest is necessary after physical activity. But we can underestimate its importance after mental activity, too. Deliberate practice needs to be sustainable for the long term. How long a person keeps at a skill is often far more important than how many hours a day they spend on it.

When you’re practicing deliberately, truly practice. When you’re recuperating, truly relax. No one can spend every waking hour on deliberate practice.

Sleep is a vital part of deliberate practice. Being asleep doesn’t mean you’re not still improving your skill. We consolidate memories at night, moving them from short-term to long-term memory. And we can’t exactly benefit from deliberate practice sessions if we don’t remember what we learn each time. Not only that, but sleep deprivation also results in a plethora of negative cognitive effects that impact performance. If we skimp on sleep, we’re likely to forget far more of what we learn during deliberate practice sessions, rendering them less useful.

When you’re not engaging in deliberate practice, your brain is still at work. During deliberate practice, we’re in focused mode. When we let our minds wander freely while at rest, we’re in diffuse mode. Although that time feels less productive, it’s when we form connections and mull over problems. Both modes of thinking are equally valuable, but it’s the harmony between them that matters. We can’t maintain the effort of the focused mode for long. At some point, we need to relax and slip into the diffuse mode. Learning a complex skill—a language, a musical instrument, chess, a mental model—requires both modes to work together. We master the details in focused mode, then comprehend how everything fits together in diffuse mode. It’s about combining creativity with execution. How to implement this: Make a list of activities you can engage in without too much conscious thought, letting yourself daydream while you do them. Common examples include going for a walk, washing the dishes, taking a shower, free-writing in a journal, playing with a toy like Lego, driving a familiar route, gardening, cooking, listening to music, or just gazing out the window. When you feel yourself getting tired or hitting a roadblock during deliberate practice, don’t keep pushing for too long. You want to be stretching yourself, not exhausting yourself. Instead, switch to one of those more relaxing activities

for at least five minutes. You'll likely come back to practice with new connections or at last feeling refreshed.

When you're practicing deliberately, truly practice. When you're recuperating, truly relax. No one can spend every waking hour on deliberate practice.

fs

Deliberate practice involves constant feedback and measurement

"Deliberate practice is hard. It hurts. But it works. More of it equals better performance and tons of it equals great performance." —Geoff Colvin, *Talent Is Overrated*

Practicing something without knowing whether you are getting better is pointless. Yet that is what most of us do every day without thinking.

As we saw before, deliberate practice involves continuously stretching yourself to improve on weak areas of a skill. For that to work, practitioners require constant feedback about their current level of performance so they can identify what works for making it better. What gets measured gets managed. To engage in deliberate practice, you need a way of measuring the most instructive metrics related to your performance. Seeing how those metrics change is the sole way to know if practice is working or not. Top performers across fields tend to spend time examining their past performance with care to identify areas for improvement. For example, a tennis player might film themselves playing a match so they can go through the footage frame by frame afterward. This provides valuable feedback, because they can figure out what might have held them back during weaker moments. In fields such as sports and chess, measuring performance tends to be straightforward. In other areas such as business, measurements are harder to take, and there may be no established markers of success. The influence of random factors may also be stronger, making it less clear whether technique changes are actually having an influence or not. When you engage in deliberate practice, it's always important to be aware of how strongly correlated your practice and your performance are likely to be.

When measuring your performance, beware of vanity metrics. These are numbers that are easy to calculate and feel good to boost. But they don't actually move the needle towards the real improvements in performance that help you reach your goals. For example, let's say you're using deliberate practice to improve the skill of email marketing, as part of the wider goal of getting more customers for your business. The number of email subscribers is a vanity metric; the number of paying customers is a useful metric. It's completely possible to increase the former without a corresponding increase in the latter.

How to implement this: Identify the most significant metrics related to performance in your chosen skill and keep a record of them each time you practice. It's easy to fool yourself

without a clear record of how you're doing. You might want to break the skill down into a few different parts to measure it, but make sure you're not fixating on vanity metrics. Deliberate practice is most effective with the help of a coach or some kind of teacher *"The best teacher is not the one who knows most but the one who is most capable of reducing knowledge to that simple compound of the obvious and wonderful."* —H.L. Mencken (attributed)

Deliberate practice is most effective when conducted with some kind of coach who can give feedback, point out errors, suggest techniques for improvement, and provide vital motivation. Although mastering any skill requires a lot of time engaging in solitary practice, working with a coach at least some of the time is incredibly valuable. In some fields such as sports and music, it's common for a coach to be present all of the time. But most top performers benefit from a combination of coaching and solitary practice.

When we look at the lives of people who achieved great things, we often find that those who did so at a young age or in a shorter time than expected benefited from having fantastic teachers. For example, physicist Werner Heisenberg had the epiphany that led to the formulation of matrix mechanics a mere five years after commencing serious study of physics. But he no doubt benefited from the mentorship of Niels Bohr and Max Born, two of the foremost physicists at the time.

Even people at the most elite levels of performance across fields can benefit from specialist coaching. Engaging in something and teaching that thing are separate skills in themselves. The best practitioners are not always the best teachers because teaching is a skill in itself.

Ericsson explained that *"the best way to get past any barrier is to come at it from a different direction, which is one reason it is useful to work with a teacher or coach."* We often make the same mistakes again and again because we simply don't realize what we're doing. Our performance falls into ruts and we can't figure out why we're running into the same problem yet again.

A coach can see your performance from the outside, without the influence of overconfidence and other biases. They can identify your blind spots. They can help you interpret key metrics and feedback.

Ericsson went on to say that *"even the most motivated and intelligent student will advance more quickly under the tutelage of someone who knows the best order in which to learn things, who understands and can demonstrate the proper way to perform various skills, who can provide useful feedback, and who can devise practice activities designed to overcome particular weaknesses."* An experienced coach will have worked with many people on the same skill so they'll be able to advise on the best ways to structure practice. They'll know when you're just repeating what you find easy, and they'll be able to push you to the next level.

Teachers or coaches see what you miss and make you aware of where you're falling short. Geoff Colvin writes:

In some fields, especially intellectual ones such as the arts, sciences, and business, people may eventually become skilled enough to design their own practice. But anyone who thinks they've outgrown the benefits of a teacher's help should at least question that view. There's a reason why the world's best golfers still go to teachers.

But what if you don't have access to a coach? What if you don't have the means to hire one or one isn't available for your particular skill? In that case, it's still possible to apply the same principles that make a coach useful by yourself. Top performers across fields build the skill of metacognition, essentially making it possible for them to coach themselves.

Colvin explains:

The best performers observe themselves closely. They are in effect able to step outside themselves, monitor what is happening in their own minds, and ask how it's going.

Researchers call this metacognition—knowledge about your own knowledge, thinking

about your own thinking. Top performers do this much more systematically than others do; it's an established part of their routine.

...A critical part of self-evaluation is deciding what caused those errors. Average performers believe their errors were caused by factors outside their control: my opponent got lucky; the task was too hard; I just don't have the natural ability for this. Top performers, by contrast, believe they are responsible for their errors. Note that this is not just a difference of personality or attitude. Recall that the best performers have set highly specific, technique-based goals and strategies for themselves; they have thought through exactly how they intend to achieve what they want. So when something doesn't work, they can relate the failure to specific elements of their performance that may have misfired.

How to implement this: Don't expect the same teacher to suit you forever. We usually need different teachers as our skill level progresses because we outgrow them. One attribute of a good teacher is that they know when to tell a student to move on. As we reach expert levels of performance, we need teachers who are themselves experts. If they're always a step ahead, we can learn from their mistakes instead of making our own.

You get the best results from working with a coach if you show yourself to be receptive to constructive criticism, even if it's uncomfortable to hear. If you respond badly, you disincentivize them from telling you what's most useful to know. Top performers know the goal is to get better, not just to hear you're already great.

Deliberate practice requires intrinsic motivation

Persisting with deliberate practice despite its innate difficulty and discomfort requires a lot of motivation. But that motivation needs to be intrinsic, meaning that it comes from inside us because we find an activity enjoyable for its own sake. This is in contrast to extrinsic motivation, where we participate in an activity to gain an external reward or avoid a negative consequence. Yet another reason why rest is important for deliberate practice is because it helps sustain motivation.

Although deliberate practice can lead to external rewards for using a skill (such as winning a competition or getting a promotion), this should not be the sole reason for practicing it. Extrinsic motivation is unlikely to be enough to get us through the long period of struggle necessary to master a skill. Becoming proficient at anything means spending time failing repeatedly at it, during which there are few external rewards. But if we enjoy getting better for its own sake, we have more of a chance of persevering until our practice starts paying off. We can navigate obstacles because we want to see where the road might take us—the obstacles aren't roadblocks.

If you want to use deliberate practice to master a skill, you need to be willing to keep practicing it no matter what. Although brute force and rewarding yourself can be effective in the short run, it won't work forever. If you're planning to engage in deliberate practice to reach expert-level performance, make sure it's a prospect you feel excited about even if it won't always be fun.

Extrinsic motivation isn't always ineffective, however. People who engage in consistent, sustainable deliberate practice tend to be adept at knowing when and how they need to employ external incentives. It's important to reward yourself when you make progress in your practice and reflect on how far you've come, not just how far is left to go.

The need for intrinsic motivation is one reason why children who are pushed to develop a skill from a young age by their parents don't always end up reaching a high level of performance and often quit as soon as they can.

How to implement this: Make a list of the reasons you want to work on a skill and the benefits getting better at it might bring. Before you begin a deep practice session, reread the list to remind you of why you're bringing your full focus to something difficult. You could also list some of the benefits you've experienced from it in the past or include quotes from

top performers in your field you find inspiring. It might feel cheesy, but it can provide a powerful boost during particularly difficult practice moments. Try to focus on intrinsic reasons and benefits, such as feeling fulfilled.

Keep a “motivation diary” for one week (or longer if possible.) Try setting an alarm to go off every fifteen minutes during each practice session. When the alarm sounds, score your motivation level out of ten (or whichever scale you prefer.) At the end of the week, review your notes to look for any patterns. For example, you might find that you begin to feel demotivated once you’ve been practicing for more than an hour, or that you feel more motivated in the morning, or some other pattern. This information could be enlightening for planning future deliberate practice sessions, even if it may disrupt your focus at the time. Another method is to simply take notes each day, documenting your current level of motivation to work on your chosen skill. Pay attention to any recurring influences. For example, you might feel more motivated to improve your skill after speaking with a more proficient friend, but less motivated after a bad night’s sleep.

One potent option for sustaining motivation is to find someone who can be a reliable cheerleader for you. In an Ask Me Anything session for Farnam Street members, Tesla co-founder Marc Tarpenning explained that having a cofounder is vital for entrepreneurs because partnering with someone else helps sustain motivation. It’s rare that both founders feel demotivated on the same day. So if one is struggling, the other can provide the encouragement needed to stay resilient. Having someone to provide extrinsic motivation when you need it can help you persevere at deliberate practice. Your cheerleader doesn’t necessarily need to be working on the same skill themselves. They just need to understand your reasons and be willing to remind you of them when you start to doubt whether the hard work is worthwhile.

Deliberate practice takes time and can be a lifelong process

Although deliberate practice tends to result in much faster progress than normal practice, truly mastering a skill is a lifelong process. Reaching the top of a field can take years or even decades, depending on its competitiveness. As the bar for success in many areas keeps rising, more deliberate practice is required to stand out.

When we applaud the top people in any field, we often fail to appreciate that their success almost always came after many years of deliberate practice, which Robert Greene refers to in *Mastery* as “a largely self-directed apprenticeship that lasts some five to ten years [and] receives little attention because it does not contain stories of great achievement or discovery.” They may have ultimately benefited from a lucky break, but their extensive preparation meant they were ready for it. Great achievements tend to come later in life or even near the ends of careers. Those who succeeded young started very young.

Throughout Ericsson’s decades of research, he searched high and low for an example of a true prodigy: someone born with an innate, remarkable talent. He never found a single proven example. Instead, he discovered that people labeled as prodigies invariably put in enormous amounts of deliberate practice—they just often obscured it on purpose or started at a young age.

Although innate differences count when beginning to learn something (and people who begin with advantages may be more likely to persist), in the long run, deliberate practice always wins out.

David Shenk writes in *The Genius in All of Us*: “Short-term intensity cannot replace long-term commitment. Many crucial changes take place over long periods of time.

Physiologically, it’s impossible to become great overnight.”

According to psychologist John Hayes, creative genius tends to come after ten years of studying relevant knowledge and developing skills. Hayes referred to this as the “ten years of silence.” In a study of seventy-six composers with sufficient biographical data available listed in *The Lives of the Great Composers*, Hayes found they almost always created their first notable works (defined as being those for which at least five different recordings were

available at the time) at least ten years after commencing a serious study of music. Just three of the five hundred works Hayes included in his sample were composed after less than a decade of preparation—and those were produced in years eight or nine. In additional studies, Hayes found similar patterns for painters and poets.

Later research reinforces Hayes' findings, and any casual survey of the lives of people widely considered to be geniuses tends to show a similar pattern. Making a breakthrough takes time. When it seems like someone was an overnight success, there's almost always a long period of silent deliberate practice preceding it. Innate talents are just a starting point. If we want to master a skill, we need to commit to working on it for a lengthy period of time, likely with few rewards. While there are no assurances that with struggle comes reward, without it the odds are lower.

Not only do world-class performers spend a long time getting good at their core skill, those in creative fields tend to produce an enormous quantity of work before gaining recognition. For every piece of work we're familiar with, there are likely dozens or even hundreds of others few people remember or ever saw.

For example, British prime minister Winston Churchill was known for his masterful public speaking. One of his best-known speeches "We Shall Fight on the Beaches," given in June 1940, displayed the extent of his command of oration and helped build morale at the time. But it's hard to overstate how prolific Churchill was as a speaker, giving an estimated 3,000 speeches during his political career. For every speech—an average of one per week between 1900 and 1955—he used deliberate practice to prepare. He engaged in focused rehearsals in front of a mirror, taking notes as he went to inform modifications. Churchill also left nothing to chance, planning his pauses and movements in advance. As well as devising his own techniques for added impact, he memorized the works of some of history's most inspiring orators.

Although he doubtless began with a degree of innate talent (his father, Randolph Churchill, was also an admired orator), Churchill clearly used extensive deliberate practice to build upon it. While this impressive resume and history solidified his place on the throne of oratorical excellence, it's important to note that he wasn't a "born speaker"—in fact, he made many mistakes. And he learned from them. If you want to produce a masterpiece, you need to accept that you'll make a lot of less remarkable work first.

Deliberate practice requires intense focus

"You seldom improve much without giving the task your full attention." —Karl Anders Ericsson

The deeper we focus during deliberate practice sessions, the more we get out of them. Intense focus allows us to increase skills and break through plateaus. Developing your attention span can have a huge impact on your life. When asked about his success, Charlie Munger once said, *"I succeeded because I have a long attention span."*

The authors of *The Game Before the Game* write, *"If you can pay attention for only five minutes in practice, then take a break every five minutes. If you can pay attention for only twenty balls, don't hit fifty. To be able to practice longer and maintain the quality of the practice, train yourself to pay attention for longer periods of time....Productive practice is about how present you can stay with your intention and is measured in the quality of the experience as opposed to the quantity of time used."*

A benefit of getting constant feedback is that it shows you what moves the needle towards improved performance and what is just running in place. Certain practice activities can feel good without having any impact. Top performers prioritize knowing what to prioritize. They always start with the most important thing because anything else is a distraction.

Intense focus is a multiplier of everything else. Keeping an eye on key metrics enables top performers to identify and systematically remove distractions from their lives. To be the best, you need to focus on both the micro and macro level. You need to pay full attention to what you're doing in the current practice sessions, and you need to know how it fits into

the bigger picture of your desired trajectory. Deliberate practice is part of the exploit phase of selecting opportunities.

As the authors of the *International Handbook of Research in Professional and Practice-Based Learning* write, “*Practicing the right things is at the core of the theory of deliberate practice.*”

How to implement this: Put the big rocks in first. You can do anything, but you can’t do everything. Figure out which practice activities have the biggest influence on your performance and plan to engage in those first before you even consider activities that offer marginal gains.

Deliberate practice leverages the spacing effect

One reason why consistent deliberate practice sessions over the course of years are more effective than longer sessions for a shorter period of time relates to the spacing effect. We can’t approach learning a skill through deliberate practice in the same way we quite likely approached studying for tests in school. If we better understand how our minds work, we can use them in the optimal way for learning. By leveraging the spacing effect, we can encode valuable knowledge related to our particular skill for life during practice sessions. Memory mastery comes from repeated exposure to the same material. The spacing effect refers to how we are better able to recall information and concepts if we learn them in multiple sessions with increasingly large intervals between them. The most effective way to learn new information is through spaced repetition. It works for learning almost anything, and research has provided robust evidence of its efficacy for people of all ages—and even for animals.

Spaced repetition is also satisfying because it keeps us on the edge of our abilities (which, as we saw earlier, is a core element of deliberate practice.) Spaced sessions allow us to invest less total time to memorize than one single session, whereas we might get bored while going over the same material again and again in a single session. Of course, when we’re bored we pay less and less attention. The authors of *Focused Determination* put it this way:

There is also minimal variation in the way the material is presented to the brain when it is repeatedly visited over a short time. This tends to decrease our learning. In contrast, when repetition learning takes place over a longer period, it is more likely that the materials are presented differently. We have to retrieve the previously learned information from memory and hence reinforce it. All of this leads us to become more interested in the content and therefore more receptive to learning it.

We simply cannot practice something once and expect it to stick.

By engaging in deliberate practice on a regular basis, even if each practice session is short, we leverage the power of the spacing effect. Once we learn something through spaced repetition, it actually sticks with us. After a certain point, we may only need to revisit it every few years to keep our knowledge fresh. Even if we seem to forget something between repetitions, it later proves easier to relearn.

How to implement this: Forget about cramming. Each time you’re learning a new component of a skill, make a schedule for when you’ll review it. Typical systems involve going over information after an hour, then a day, then every other day, then weekly, then fortnightly, then monthly, then every six months, then yearly. Guess correctly and the information moves to the next level and is reviewed less often. Guess incorrectly and it moves down a level and is reviewed more often.

The history of deliberate practice

Karl Anders Ericsson: The expert on expertise

“*Learning isn’t a way of reaching one’s potential but rather a way of developing it.*” —Karl Anders Ericsson, *Peak*

The concept of deliberate practice is attributed to Florida State University psychologist Karl Anders Ericsson, who along with his collaborators performed pioneering research in the field of expert performance. Ericsson spent decades seeking to answer the question of what it takes to become really good at something difficult. His research often focused on medicine, music, and sports.

Ericsson's interest in expert performance kicked off in the late 1970s, when he began working with psychologist Bill Chase at Carnegie Mellon University to study short-term memory. Together, they began a series of experiments to see how many random digits it's possible to memorize after hearing them once. Ericsson and Chase used an undergrad named Steve Faloan as their guinea pig. For a few hours each week, they read out numbers and Faloan repeated as many as he could recall.

Although the experiment might sound dull, they uncovered something intriguing. In a 1982 paper entitled "Exceptional Memory," Ericsson and Chase summarized their findings. Previously, researchers believed the average person could hold just seven random digits in their short-term memory. Yet with careful practice, Faloan began to remember more and more numbers. At his peak and after 200 hours of practice, he could recall 82 digits. To assess if this was a fluke, Ericsson tried the same with a friend, Dario Donatelli. Five years later, Donatelli could recall 113 digits. Both he and Faloan went far beyond what seemed to be an immovable ceiling on human performance and blew past existing world records. The experience of seeing two people who started off with ordinary memories enhance their capabilities in such a drastic way inspired Ericsson to further study the effects of practice on skills. Could it be that extraordinary abilities came from extraordinary practice, not just innate ability?

Through his studies of expert performers in a range of fields, Ericsson concluded they practiced their skills in a fundamentally different way than amateur practitioners. Ericsson described this kind of practice as "deliberate" due to its methodical, hyper-conscious nature. He argued that experts become experts largely as a result of the way they practice. They may benefit from innate advantages, but their talents themselves are not innate. Ericsson also believed that the standards in many additional fields could be improved far beyond their current level if practitioners employed the principles of deliberate practice. Indeed, many fields have seen remarkable increases in their standards for high performance over time. Today, high-schoolers manage athletic feats that were once Olympic level and children play music once considered world-class. This is possible because of better training and knowledge of what it takes to be the best. The more we improve how we train, the more we expand our range of possible performance.

In 2016, Ericsson published *Peak: Secrets from the New Science of Expertise*, a popular science book condensing his learnings from thirty years of research. He also co-edited the 2006 *Cambridge Handbook of Expertise and Expert Performance*.

Malcolm Gladwell: The 10,000 hour rule

The widespread awareness of Ericsson's work outside the scientific community is in part a result of Malcolm Gladwell's 2008 book, *Outliers: The Story of Success*. In the book, Gladwell attributed unusual success in different fields to a mixture of lucky factors (such as when or where a person was born) and around 10,000 hours of practice. He based this figure on research, including Ericsson's, that suggested top performers tended to have put in about that amount of time before reaching peak performance.

Gladwell showed how the success of Bill Gates, the Beatles, and other outstanding performers is not so much to do with what they are like but rather where they come from. "The people who stand before kings may look like they did it all by themselves," Gladwell writes. "But in fact they are invariably the beneficiaries of hidden advantages and extraordinary opportunities and cultural legacies that allow them to learn and work hard and make sense of the world in ways others cannot."

The so-called “10,000 hours rule” caught on. It’s a catchy idea, and many people took it to mean that anyone can master anything if they just put the time in. Ericsson himself disputed Gladwell’s representations of his research, which led to the widespread belief that the time someone spends practicing predicts their success, without emphasizing the quality of their practice.

Although the backlash against Gladwell’s calculation has arguably been exaggerated, it’s important to stress that research into deliberate practice emphasizes quality of practice, not quantity. It’s all too possible to spend 10,000 hours engaging in a skill without serious improvements. For example, most of us spend hours per day typing, yet we don’t see continuous improvements in speed and quality because we’re not using deliberate practice.

The useful takeaway from the “10,000 hours rule” is simply that it takes a lot of work to become the best. There’s no magic number of practice sessions, and everyone’s path will look different. Just because successful people in a given field have spent around 10,000 hours practicing their key skill, that doesn’t mean every person who practices that skill for 10,000 hours will become successful.

The limitations and downsides of deliberate practice

Part of us wants to believe expert performance is something innate and magical so we can recuse ourselves from hard work. The other part of us wants to believe that it’s something earned through blood, sweat, and tears—that we too could achieve amazing performance, if only we could devote ourselves to something.

Deliberate practice, in reality, is far more complex and nuanced than many people would have you believe. It’s not a panacea, and it won’t solve all of your work- and art-related problems. Let’s take a look at some of the limitations of deliberate practice.

First of all, deliberate practice is a necessary but insufficient part of becoming a world-class performer. You can’t rise to the top without it. But it’s not enough on its own to be the absolute best in any field. Once you reach higher echelons for any skill, everyone is engaging in a lot of deliberate practice.

If you’re aiming at expertise or just really good performance, deliberate practice will most likely get you there. But the higher you rise, the more luck and randomness end up mattering. However much you engage in deliberate practice, you can’t control the chance events (good or bad) that dictate a great deal of life.

When we look at the lives of top performers, they often benefited from specific backgrounds or opportunities, in addition to engaging in deliberate practice. For example, if you’re trying to become a champion chess player, it’s a big boost if your mother was a champion chess player. Not only will you have potential genetic advantages, you’ll have also likely grown up hearing about chess, been encouraged to practice it from a young age, and have someone to turn to for advice.

Seeing as it takes years of consistent deliberate practice to master a skill, people who begin early in life have an advantage over those who start later on. That doesn’t mean you can’t become exceptional at something you discover well into adulthood (just look at [Julia Child](#) or check out the book [Guitar Zero](#)). But it does mean that people who begin deliberate practice as kids are more likely to enjoy the success that makes it possible to keep committing to it. If you’re trying to master a skill while also having to work an unrelated job, care for your family, and deal with the other myriad responsibilities of adult life, you likely will have less room for it than a ten-year-old.

People who discover they want to master a skill or are encouraged to do so by others early in life have an advantage. Once the opportunity for practice is in place, the prospects of high achievement take off. And if practice is denied or diminished, no amount of talent is going to get you there.

In addition to lucky circumstances, high performers benefit from a combination of deliberate practice and innate talents or physical advantages. However much you practice, certain physical limitations are insurmountable. For example, if you're 165 centimeters tall, you're unlikely to become a professional basketball player. There are some physical abilities, such as particular kinds of flexibility, that can only be developed at a young age when a person's skeletal structure is still forming. It's important to be realistic about your starting point and be aware of any limitations. But that doesn't mean you can't develop workarounds or even use them to your advantage.

Another downside of deliberate practice is that the level of focus it requires can mean practitioners miss out on other parts of life. Top performers often devote almost every waking hour to practice, recuperation from practice, and support activities. For example, a professional dancer might spend several hours a day on deliberate practice with all of the remaining hours going toward sleep, low-impact exercise, stretching, preparing nutritious food, icing his feet, and so on. There is enormous satisfaction in the flow states produced by deliberate practice, but practitioners can absolutely miss out on other sources of happiness, such as spending time with friends.

Deliberate practice is part of the exploit phase of new opportunities. Yet sometimes we can end up having too much grit. We can keep persevering with the skill we're practicing right now, remaining overly passionate, past the point where it serves us. We can wear ourselves out or get hurt or fail to realize when it's no longer worth practicing a skill. For example, a new technology might mean our skill is no longer valuable. If we keep on deliberately practicing due to sunk costs, we'll be unlikely to see many long-term benefits from it. A crucial skill in life is knowing when to pivot. Focusing too much on our goals can blind us to risks.

In some fields, expertise is hard to quantify or measure, which makes it less clear how to structure practice. There may be no single target to hit or universal rule for what improves performance.

A final limitation to keep in mind is that, as Ericsson explained, *"the cognitive and physical changes caused by training require upkeep. Stop training and they go away."* If someone can't practice for a period of time, such as due to an injury or having a child, they're likely to see the skills they developed through deliberate practice deteriorate.

Summary

Deliberate practice isn't everything, but if you want to keep improving at a skill or overcome a plateau, you'll benefit from incorporating the principles mentioned in this article. To recap:

- Deliberate practice means practicing with a clear awareness of the specific components of a skill we're aiming to improve and exactly how to improve them.
- The more we engage in deliberate practice, the greater our capabilities become.
- Our minds and bodies are far more malleable than we usually realize.
- Deliberate practice is structured and methodical.
- Deliberate practice is challenging because it involves constantly pushing yourself out of your comfort zone.
- Deliberate practice requires constant feedback and measurement of informative metrics—not vanity metrics.
- Deliberate practice works best with the help of a teacher or coach.

- Continuing deliberate practice requires a great deal of intrinsic motivation.
- Deliberate practice requires constant, intense focus.
- Deliberate practice leverages the spacing effect—meaning a consistent commitment over time is crucial.
- If you're content with your current level of skill or just doing something for fun, you don't necessarily need to engage in deliberate practice
- Deliberate practice is best suited to pursuits where you're actively aiming for a high level of performance or to break beyond some kind of supposed limit.

53. Accelerated Learning: Learn Faster and Remember More

You can train your brain to retain knowledge and insight better by understanding how you learn. Once you understand the keys to learning, everything changes—from the way you ask questions to the way you consume information. People will think you have a superpower.

Learning is the act of incorporating new facts, concepts, and abilities into our brains. We start learning in the womb and we never stop; we are always developing new competencies. Every new bit of knowledge we acquire builds on what we already know and gives us a fuller, richer picture of the world. And the more developed our understanding of the world is, the easier it is for us to adapt and pivot when our circumstances change.

We know from biology that organisms that can adapt to their constantly changing environment survive and thrive. Those that can't eventually go extinct. The same is true for us in our life and work. We all know the person at work that hasn't adapted to the changing times. Their unwillingness to stretch themselves and learn something new makes it seem like they are moving backwards.

People can end up stuck with a static amount of knowledge because we don't just passively absorb new ideas and information. Learning something new requires active engagement. At FS, we see learning as part of our daily job. We get better to help you get better, and we give you the tools to learn.

The greatest enemy of learning is what you think you know. When you think you know something, learning something new means you might have to change your mind, so it's easy to think there's no room for new ideas. But not wanting to change your mind will keep you stuck in the same place. Overcoming our egos can be one of the big challenges of learning. Therefore, being willing to admit when you're wrong and adjust your thinking is the thing that will help you learn the most. The first step to learning is recognizing your ignorance and deciding to do something about it.

At FS, we believe that thriving in life means relentless lifelong learning. Things change quickly, and you can't coast on what you already know. The best approach you can take towards learning is one that helps you go to bed a little bit smarter each day.

WHY WE'RE BAD AT LEARNING

One reason why we're bad at learning is that we bring a lot of baggage to it—baggage we often pick up early in life and then struggle to let go of later. If you can let go of assumptions about what you *should* do, you can learn much more effectively. One major piece of baggage we accrue is the belief that if we're not visibly active, we're not learning. This is incorrect. Learning requires time to reflect. It requires discussing what you've learned and letting your mind wander. You need to let go of trying to *look* smart, and focus instead on trying to *be* smart.

We sometimes struggle with learning because we expect it to be easy. We'd all like to find a silver bullet: a quick, easy shortcut to picking up whatever we want and never forgetting it. The internet teems with blog posts promising you can learn a language in a week or to code in a month or how to play the violin overnight. This is all bull. Learning isn't just knowing something for a day. It's deep wisdom that allows you to create, innovate, and push boundaries.

Another reason we're bad at learning is that the modern world erodes our attention spans by training us to be in a constant state of distraction. It might feel good in the moment to jump to the latest ping on your phone, but learning requires deep focus. When you're in a distracted state, new information can't fix itself in your mind, and you end up with gaps in your understanding. Focusing is an art—through experimentation and creativity, you can build systems that let you give your full attention to whatever you're learning.

When we talk about accelerated learning at FS, we don't mean you can overcome the need for hard work. We mean it's possible to find ways of learning that give you tangible results, instead of using ones that waste time or get you nowhere. But no matter what, you still need to do the work. Learning should be difficult, but that doesn't mean it can't be fun. In fact, you enhance your skills the most when you stretch yourself to the limits of your abilities. Pushing yourself to the point that feels challenging yet doable is the foundation of deliberate practice, the technique elite people in every field use to grow their expertise. Outside of your intellectual comfort zone is where you experience the greatest learning. For this reason, having a lot of helpful guidance early on can be counterproductive if it eliminates the all-important struggle to master new material.

You might fail if you move beyond what you find comfortable. You might apply new knowledge incorrectly or misunderstand the key points of an argument in a new field. This is painful. It also offers the opportunity to learn from your failures. We all hate looking dumb, but you can't let failure dissuade you from trying to expand your circle of competence.

TWO MAIN SOURCES OF LEARNING

There are two main places we can learn from: our own experience and history, or the experience of others. Exploring the distinction between the two can show us the best ways to learn from each of them.

Learning from history

You can learn from the experiences of others by studying history and applying its lessons to the present. History tends to repeat itself, so the dilemmas and decisions you face today often have historical antecedents. Studying the past helps us know how to shape the future. History is one of our biggest sources of fundamental knowledge.

Any time you learn from the past, remember that knowledge collapses over time. Much of what you know today will one day prove false, just like much of what people knew a century, fifty years, or even a decade ago has since proved false. Facts have a half-life, one that can be especially short in fields like medicine and the social sciences.

It is a mistake to think we have reached the endpoint of human knowledge, or that anything you learn now will be true forever. When you learn from history, you draw from lessons shaped by the perspective of the person who captured what happened. Thus,

historical knowledge is something to continuously update as you learn both from what happened and how you choose to look at it.

Learning from experience and reflection

In addition to reading, direct experience is the other main way we learn.

Double loop learning is a way of updating your opinions and ideas in response to new evidence and experience. When you keep repeating the same mistakes, you're using single loop learning. It doesn't get you far. When you reflect on experiences, collect new data, and make an active effort to seek out feedback, you're using double loop learning. Reflection allows you to distill experience into learning. Don't just "do," think about what you're doing and what you've done. High performers make adjustments based on both their successes and failures.

LEARN BETTER

We recommend the following two proven techniques for improving your learning.

The Feynman Technique

If you want to supercharge your learning, the single most effective technique we've uncovered for absorbing new concepts comes from the famed Nobel Prize-winning physicist Richard Feynman. The Feynman Technique ensures you understand what you learn. It includes the following four steps:

1. Choose a concept you wish to learn about.
2. Pretend you are teaching it to a child—a sixth-grader, specifically. Write your explanation down or say it out loud.
3. Identify any gaps in your understanding that might show up when you try to simplify the concept; go back to the source material to find the information you need.
4. Review and simplify your explanation again.

It works because writing out a concept in language a child would understand forces you to understand it at a deeper level. Sometimes we use jargon and complicated language to hide what we don't understand. The Feynman Technique lays bare the true extent of our knowledge.

Similarly, asking better questions is a route to faster learning. The most mundane questions—the ones a sixth-grader might ask—can sometimes teach us the most because they require an explanation that digs into the details.

How do you know if you've truly learned a new concept? Feynman proposed a simple alternate test: try to rephrase it in your own language without using its actual name. For instance, describe what enables a dog to run without using the word "energy."

Spaced repetition

Rote memorization doesn't work. Period. The key to effective learning is spaced repetition, a technique that works *with* the way your brain naturally retains information, not against it. Spaced repetition involves revising information at increasing intervals. This reflects and combats the fact that once you learn something you gradually forget it, with the forgetting happening fast at first, then leveling off. Using spaced repetition, you remind yourself of information often at first, then less often.

Memory mastery comes from repeated exposure to new material. In order to learn something, you need to retrieve it from memory again and again. Retrieval makes information stick even better than re-exposing yourself to the original material.

ARTICLES ON ACCELERATED LEARNING

- The more we learn about the world, the more we can learn about ourselves, according to Nietzsche.

- “Knowledge makes everything simpler”: advice for learning from executive and technologist John Maeda, including why you should teach yourself the basics and why metaphors are powerful for transferring information across contexts.
- Charles Darwin may not have had an unusually high IQ, but he was able to outpace other thinkers by learning how to balance out his deficiencies.
- Ken Iverson, the former CEO of Nucor Steel, believed MBAs should focus on teaching students how to understand and lead people above all else.
- Harvard biologist/psychologist Steven Pinker’s career is a testament to the benefits of multidisciplinary thinking. Here’s what he believes students should learn as part of a thorough education.
- In a charming letter to his son Hans, Albert Einstein said the best way to learn is to enjoy something to the point where you don’t even notice the time passing.
- Even the most skilled teachers struggle to overcome the reality that we forget most information shortly after being exposed to it. Effective learning requires building your own understanding, with the guidance of an expert teacher.
- Chess and martial arts genius Josh Waitzkin teaches us that the art of learning requires first mastering the fundamentals by breaking a skill down into blocks.
- “Mozart’s Brain and the Fighter Pilot” shows us that we get smarter by exercising our cognitive powers in the same way that we get stronger by exercising our muscles.
- Never learning to paint via the conventional route helped Vincent van Gogh approach his work in a unique way, noticing details a trained artist might not have.

THE BEST BOOKS ON LEARNING

- *The Art of Learning: An Inner Journey to Optimal Performance*, Joshua Waitzkin
- *The Laws of Simplicity*, John Maeda
- *Make It Stick: The Science of Successful Learning*, Peter C. Brown, Henry L. Roediger III, and Mark A. McDaniel
- *Mindshift: Break Through Obstacles to Learning and Discover Your Hidden Potential*, Barbara Oakley
- *Ultralearning: Master Hard Skills, Outsmart the Competition, and Accelerate Your Career*, Scott H. Young
- *Mastery*, Robert Greene
- *Brain Rules: 12 Principles for Surviving and Thriving at Work, Home, and School*, John Medina
- *Deep Work: Rules for Focuses Success in a Distracted World*, Cal Newport
- *Mindset: The New Psychology of Success*, Carol S. Dweck
- *The Talent Code*, Daniel Coyle

CONCLUSION

Learning isn't something you do at the behest of someone else. You're responsible for it. According to the prolific author Louis L'Amour, all education is self-education. If you don't take charge of your learning, no one else will. Maya Angelou and George Washington took the same view. It's up to you to build the habit of lifelong learning.

USE Feynman Technique

Feynman Technique

- I. **Choose a Concept, Idea, topic to Learn. Select a Topic You are interested in learning about and write it at the top of the blank page in the Notebook or Paper.**
 - A. Choose your topics carefully: Not everything that you study suits this technique. Usually abstract complex ideas are best understood by Feynman technique but ideas that are evidence-based/observational might not really be suited for this.
 - B. Selecting a concept to study compels you to be intentional about what you don't know. It also forces you to choose a topic that's small enough that it could reasonably fit onto one or several pages.
 - C. **You face what you don't know.** By writing a topic down on a blank page, you acknowledge you're starting from scratch or at least filling in some blanks. In doing so, take the initial step in the process.
 - D. **You need to be specific.** Given the accumulated knowledge in the universe, most of us know nothing about most things! Writing down explicitly what you don't know provides you with a starting point.
- II. **Use It For Real.**
 - A. Use it for real: perfectly suitable for weekly tech-talks, lectures, paper-reading, Study, Bible Study, Sermon or any type of study, deep work and deep study sessions.

III. Study The Topic By Reading, Listening, Watching and Communicating.

- A. You have to start small. You really only have a page (or a few) to fill up with information. You can't fit everything there is to know about "Evolutionary Science" or "Microeconomics" or "Psychology" on a page. Instead work on smaller more defined concepts or what might reliably be found on a midterm or final exam.
- B. Fully understand the complex topic first: Don't begin the learning process by explaining it before you actually understand it. Retention methods such as Feynman technique, active-recall and spaced repetition are for solidifying information that you already understand. Trying to solidify an information before you understand it might end up encoding wrong interpretation of a topic.
- C. Actually put the time and effort: Once you have selected the correct set of topics, make sure you actually spend the time and effort to go through the entirety of the techniques. Feynman technique is great for having a basic framework of the topic inside your head with the details chopped off. It's important to get a very clear picture of the basics in your head right - the details can be filled in later.
- D. Make it your own.
 - Start with not knowing.
 - Ask 'why?'. ask why $x=y$. or why does music has 12 notes and not 14.
 - Study the story of what you are studying. E.g. study what was physics before Quantum theory. Why QT was needed, who were the people involved in developing the QT and how it changed the world.
- E. Take Notes On the Topic From Study.
- F. Consolidate the information concisely onto a flashcard or some other place for long term retention: Once we really understand a topic to be able to explain the core principles without having to use jargon, we should hold onto that understanding. Unfortunately, a large portion of that information that we just gathered is lost within first 48 hours after learning. So note it down somewhere before you lose it. Optimise for spaced-repetition for next sessions.
- G. Don't write notes on notes: Life is short.
- H. Cornell Notes.
 - How Will I Take Notes and Cornell Note Take Method Pages 79-82.

IV. Simplify The Topic For Myself First.

- A. Simplify your explanation so that YOU understand it. As long as the explanation is not simple enough for YOU to understand, spend more hours to break it down to basic, bare-bone, core ideas.
- B. Avoid jargon and complexity. The simpler the explanation, the more likely you are to remember it.
- C. Only Use Simple Words. The words a child would understand.
- D. Anyone can make a subject complicated but only someone who understands can make it simple. Jargon hides our lack of understanding. When forced to write out an idea from start to finish in simple language, you discover where you struggle, where it doesn't quite make sense, where you get frustrated, where you don't really understand as well as you thought. Only by identifying gaps in your knowledge can you fill them.
- E. But true understanding requires a more active process like *teaching*. Start out by formally teaching yourself. Write out a summary in your own words without looking at your notes. Or explain it to yourself out loud. Then take it to the next level by teaching other people. Teaching also initiates a feedback loop, where critique or questions can help us learn and sharpen our thinking.
- F. **It makes it harder to trick yourself.** When you have to truly explain something, whether through writing or aloud, you encounter the holes in your reasoning and the white spaces in your knowledge. Think of writing and teaching as a process to *obtain understanding*, not something you do once you already understand.

V. Reflect, Refine, and Simplify

- A. Only when you can explain the subject in simple terms do you understand it.
- B. Simple is beautiful.
- C. Review your notes to make sure you didn't mistakenly borrow any jargon or gloss over anything complicated.
- D. Read it out loud as if to a child. If the explanation isn't simple enough or sounds confusing, that's a good indication that you need to reflect and refine.
- E. Go back to the source material, reviewing the parts you don't quite understand yet.
- F. Repeat until you have a simple explanation.

VI. Return to the source material if you get stuck. Go back to whatever you're learning from – a book, lecture notes, Journal, Newspaper, podcast or any other resource and source – and fill the gaps in your knowledge.

A. Step 1- Use The Chosen Rules of Reading Method For Analysis, Syntopicon, Research, Investigative Journalism or Mixed Method and Follow Each Steps Of The Method Until Finish All Steps, While Re-listen Lectures, Read Books or Lecture Notes 1-100 Times For Each Step.

B. Step 2- Following Rules of Reading Methods:

C. VERY VERY FAST Reading- Skimming. Pages 47-51.

D. VERY FAST READING- Entertainment.

VII. Method 1-Speed Reading. FAST Reading. Pages 59-64.

E. FAST READING: Methods for Basic Knowledge For Deep Work or Bible Study.

I. Method 1-Survey, Question, Read, Recite, Record, Reflect (SQR4). Pages 66-67.

II. Method 2-Use 80/20 Principle For Reading. Pages 68.

III. Method 3-Preview, Question, Read, Summary, Test (PQRST). Page 69.

IV. Method 4-Flip Through Pages and Analyse. Page 70.

V. Method 5-Devotional Bible Study by Using Devotional Books. Pages 71-72.

VI. Method 6-Devotional Bible Read. Pages 73-74.

F. Deep Work, Deep Study, Bible Study or Any Book- SLOW Reading- Complex Text.

- I. Method 1-Chapter Summary Method. Pages 143-147.**
- II. Method 2-Character Quality Method. Pages 148-160.**
- III. Method 3-Thematic Method. Pages 161-163.**
- IV. Method 4-Biographical Method. Pages 164-176.**
- V. Method 5-Topical Method. Pages 177-180.**
- VI. Method 6-Word Study Method. Pages 181-189.**
- VII. Method 7-Book Background Method. Pages 190-194.**
- VIII. Method 8-Book Survey Method. Pages 195-205.**
- IX. Method 9-Chapter Analysis Method. Pages 206-215.**
- X. Method 10-Paragraph Study. Pages 216-229.**
- XI. Method 11-Verse by Verse Analysis Method. Pages 230-234.**
- XII. Method 12-Book Synthesis Method. Pages 235-238.**
- XIII. Method 13-Theological Study Method of Bible Study. Pages 239-245.**
- XIV. Method 14-Studying Bible Prophecy. Pages 246-259.**
- XV. Method 15-Typological Study Method. Pages 260-262.**
- XVI. Method 16- John MacArthur Way Bible Study. Pages 263-268.**
- XVII. Method 17-Inductive Bible Study Method. Pages 269-296.**
- XVIII. Method 18-BIBLICAL HERMENEUTICS. Pages 297-302.**
- XIX. Method 19-Theological Group of Principles. Pages 303-306.**
- XX. Method 20- How To Read A Book Pages 307.**

G. VERY VERY SLOW READING- COMPLEX TEXT. Deep Work, Shallow Work, Bible Study, Analysis of Text, Research, Investigative Journalism, Investigation and Syntopicon, Mixed Method.

- I. Method 21- How To Read A Book By Mortimer Adler Various edition Pages 341.**
- II. Method 22-How To Read A Book For Various Books. Pages 342-600.**
- III. Method 23- Syntopicon Pages 601-642.**
- IV. Method 24-The Craft of Research. Pages 644-882.**
- V. Method 25-Research Books can Be Used. Pages 883-897.**
- VI. Method 26-Investigative Journalism. Pages 898-923.**
- VII. Method 27-Mixed Methods of Rules of Reading. Pages 924-942.**

- A. Learning should be iterative. More often than not, learning something challenging takes several attempts. With the Feynman Technique, returning to the source material is an explicit part of the learning process. When gaps in our knowledge arise and our explanations aren't quite right, revisiting our primary and secondary sources can help solidify what we're learning.
- B. Getting it right will likely take several iterations. That's a good thing; the more you refine your explanations, the more your understanding will deepen. Learning becomes an iterative process. Rather than viewing learning as one-and-done, this step gives you permission to continuously refresh your knowledge.
- C. You're actively engaged. Using sources to polish our own explanations and models is an active process. When we learn passively, committing details to memory is more challenging. When we're actively part of creating our own summaries and reasoning, drawing intentionally from original information to fill our blind spots, we can more readily commit knowledge to our long-term memory.
- D. You expand your knowledge base. Paradoxically, the more we learn, the more *our capacity* to learn increases. Looking through a chapter of a textbook might feel like a different language the first time around. The second time it becomes more clear. The third time, with a strong base already, we pick up nuances we couldn't have possibly seen before.

VIII. Simplify your explanations and create analogies. Streamline your notes and explanation, further clarifying the topic until it seems obvious. Additionally, think of analogies that feel intuitive.

- A. Every field of study has its own specialised terms. While it may be important to know them, it's also important to not confuse knowing jargon with knowing concepts. The Feynman Technique involves simplifying our initial explanations and refining our understanding through simple analogies..Why this step works:
- B. Simplicity is a proxy for understanding. It's easy enough to commit terms to memory, and repeat them back when prompted. But memorisation is not understanding. When we can't rely on big words that make us sound smart, we have to distill what we truly know to the most basic form. This is where true understanding takes place.
- C. Analogies are easier to recall and explain. When you understand a challenging concept, analogies allow you to create a short-hand for recalling it quickly and explaining it to others clearly. Learning material often provides ready-made analogies for us. For example, we all probably have "the mitochondria are the powerhouse of the cell" burned into our collective memories. However, pushing ourselves to create our own analogies is even more powerful than regurgitating a borrowed one that we may not actually understand.

IX. Teach it to yourself or someone else. Write everything you know about a topic out as if you were explaining it to yourself. Alternately, actually teach it to someone else.

- A. Classic learning mistake is reading an article or textbook and considering our learning complete. In reality, reading is not understanding. We might even take notes, essentially transcribing a resource's sentences into our notebooks. We often nod to ourselves, thinking we've grasped a subject. After all, *we've taken notes*.
- B. Remove any jargon or complexity.
- C. Only Use Simple Words. The words a child would understand.
- D. Anyone can make a subject complicated but only someone who understands can make it simple. Jargon hides our lack of understanding. When forced to write out an idea from start to finish in simple language, you discover where you struggle ... where it doesn't quite make sense ... where you get frustrated ... where you don't really understand as well as you thought. Only by identifying gaps in your knowledge can you fill them.
- E. But true understanding requires a more active process like *teaching*. Start out by formally teaching yourself. Write out a summary in your own words without looking at your notes. Or explain it to yourself out loud. Then take it to the next level by teaching other people. Teaching also initiates a feedback loop, where critique or questions can help us learn and sharpen our thinking.
- F. **It makes it harder to trick yourself.** When you have to truly explain something, whether through writing or aloud, you encounter the holes in your reasoning and the white spaces in your knowledge. Think of writing and teaching as a process to *obtain understanding*, not something you do once you already understand.
- G. **It's even harder to trick others.** If an explanation you're providing doesn't make sense, they'll often tell you or you can pick up cues like blank stares. As a test, ask them to repeat what you taught them in their own words. If they can't do this, your explanation is too complex — simplify it and use plain language.
- H. **You build confidence.** When you truly understand something, it clicks. You can explain it forward and backwards, pointing out exceptions and spotting logical inconsistencies. When this happens, it builds confidence and pushes

you to tackle even more challenging subjects knowing you have a solid framework for learning.

X. Reflect, Refine, and Simplify.

- A. Only when you can explain the subject in simple terms do you understand it.**
- B. Simple is beautiful.**
- C. Review your notes to make sure you didn't mistakenly borrow any jargon or gloss over anything complicated.**
- D. Read it out loud as if to a child. If the explanation isn't simple enough or sounds confusing, that's a good indication that you need to reflect and refine.**
- E. Go back to the source material, reviewing the parts you don't quite understand yet.**
- F. Repeat until you have a simple explanation.**

XI. Return to the source material if you get stuck. Go back to whatever you're learning from – a book, lecture notes, Journal, Newspaper, podcast or any other resource and source – and fill the gaps in your knowledge.

- A. Step 1- Use The Chosen Rules of Reading Method For Analysis, Syntopicon, Research, Investigative Journalism or Mixed Method and Follow Each Steps Of The Method Until Finish All Steps, While Re-listen Lectures, Read Books or Lecture Notes 1-100 Times For Each Step.**
- B. Step 2- Following Rules of Reading Methods:**
- C. VERY VERY FAST Reading- Skimming. Pages 47-51.**
- D. VERY FAST READING- Entertainment.**
 - I. Method 1-Speed Reading. FAST Reading. Pages 59-64.**
- E. FAST READING: Methods for Basic Knowledge For Deep Work or Bible Study.**
 - I. Method 1-Survey, Question, Read, Recite, Record, Reflect (SQR4). Pages 66-67.**

- H. Learning should be iterative. More often than not, learning something challenging takes several attempts. With the Feynman Technique, returning to the source material is an explicit part of the learning process. When gaps in our knowledge arise and our explanations aren't quite right, revisiting our primary and secondary sources can help solidify what we're learning.
- I. Getting it right will likely take several iterations. That's a good thing; the more you refine your explanations, the more your understanding will deepen. Learning becomes an iterative process. Rather than viewing learning as one-and-done, this step gives you permission to continuously refresh your knowledge.
- J. You're actively engaged. Using sources to polish our own explanations and models is an active process. When we learn passively, committing details to memory is more challenging. When we're actively part of creating our own summaries and reasoning, drawing intentionally from original information to fill our blind spots, we can more readily commit knowledge to our long-term memory.
- K. You expand your knowledge base. Paradoxically, the more we learn, the more *our capacity* to learn increases. Looking through a chapter of a textbook might feel like a different language the first time around. The second time it becomes more clear. The third time, with a strong base already, we pick up nuances we couldn't have possibly seen before.

VIII. Simplify your explanations and create analogies. Streamline your notes and explanation, further clarifying the topic until it seems obvious. Additionally, think of analogies that feel intuitive.

- A. Every field of study has its own specialised terms. While it may be important to know them, it's also important to not confuse knowing jargon with knowing concepts. The Feynman Technique involves simplifying our initial explanations and refining our understanding through simple analogies..Why this step works:
- B. Simplicity is a proxy for understanding. It's easy enough to commit terms to memory, and repeat them back when prompted. But memorisation is not understanding. When we can't rely on big words that make us sound smart, we have to distill what we truly know to the most basic form. This is where true understanding takes place.
- C. Analogies are easier to recall and explain. When you understand a challenging concept, analogies allow you to create a short-hand for recalling it quickly and explaining it to others clearly. Learning material often provides ready-made analogies for us. For example, we all probably have "the mitochondria are the powerhouse of the cell" burned into our collective memories. However, pushing ourselves to create our own analogies is even more powerful than regurgitating a borrowed one that we may not actually understand.

IX. Organize and Review

- A. To test your understanding in the real world, run it by someone else. How effective was your explanation? What questions did they ask? What parts did they get confused about?
- B. When you're happy with your understanding, take the page you created with a simple explanation and put it into a binder. Following this technique for everything you learn gives you a binder full of learning that you can review a couple of times a year.

Trust the Quiz-and-Recall Method

Whether it's philosophy or calculus, the most effective way to imprint a concept is to first review it and then try to explain it, unaided, in your own words. If you can close your eyes and articulate an argument from scratch, or stare at a blank sheet of paper and reproduce a solution without a mistake, then you have fully imprinted that concept. It's not going anywhere. The same is not true if you merely read over something. Passively reviewing a concept is not the same as actively producing it. Most students make the mistake of relying only on passive review; they read and reread their notes and assignments, and assume that the more they read, the more they will remember. But as Ryan from Dartmouth warns: "Simply reading it over doesn't work. You have to make the extra effort to get it into your head."

Using the Quiz-and-Recall Method for Nontechnical Courses

To apply the quiz-and-recall method to nontechnical course material, you first need to construct a practice quiz for each chapter in your study guide. Fortunately, the questions for these quizzes already exist, since, if you've followed the advice of Steps #1 and #2, all of your notes should be in a question/evidence/conclusion format.

Therefore, the quiz for any given chapter can simply contain all of the questions from the notes you took for that chapter. You can be flexible here. If your notes contain some really broad questions—for example, an entire lecture that deals with only one idea—break them up into several smaller questions that, together, cover all of the relevant points. On the other hand, if your notes have a bunch of really small questions, you can combine some into larger questions to save space and time. This process is not an exact science; your goal is simply to produce practice quizzes that cover all the material contained in each corresponding chapter. If you can answer all the questions, then you understand all the big ideas. Once you've built your practice quizzes, go through them one by one. For each question, try to articulate the matching conclusion and provide some highlights from the supporting evidence. You don't have to reproduce the material in your notes word for word, but you do need a reasonable summary of the big idea and its support. Here's the important part: Don't do this only in your head! If you're in a private location, say your answers out loud using complete sentences.

However, if you are forced to review with other people around and you need to be quiet, then you can write out your answers. “The physical act of writing and the manipulation of the material in my mind was usually enough to keep things straight,” explains Melanie, a straight-A Dartmouth student. You don’t have to format these responses perfectly with correct spelling and grammar, but they must contain all of the pertinent information. No shortcuts. If you don’t say or write it, don’t consider it fully reviewed. Next, put little check marks on your quizzes next to any questions that you had trouble answering. Glance through your study guide to remind yourself of the right answers to these questions. Take a quick break.

Now, repeat the first step, except this time you need to answer only the questions that you marked during your first run-through. Put a new check mark next to the questions that you still have trouble with. Once again, look through your notes to get the right answers, and then take a quick break. Then go back to the practice quiz and try to answer the questions that you marked on your second run-through. You get the idea. Repeat this pattern until you complete a run-through without adding any new check marks. At this point, you’re done!

Using the Quiz-and-Recall Method for Technical Courses

The quiz-and-recall method is easily applied to technical courses. You already constructed your mega-problem sets; now you simply need to solve them. Start with the technical explanation questions—thinking about the general concepts first will make it easier to solve the specific sample problems that follow. As with nontechnical courses, try to provide an articulate answer for each problem, and if possible, give your explanation out loud, as if lecturing to a class. Otherwise, write out your answers clearly. Don't skip any important details. Once you're done with the technical explanation questions, move on to the sample problems. Try to answer each. Again, don't do this in your head. "I don't just read the material," explains Worasom, a straight-A student from Brown. "I write the important equations and concepts out by hand." Your solutions don't need to be as detailed as if this was a real assignment, but they should clearly demonstrate that you know what you're doing. If you can't explain exactly how you got from the question to the answer, then you don't yet understand this problem. Be honest with yourself: If you're just regurgitating memorized solutions, you aren't prepared to handle new questions on a test.

Memorize over Time

If you have material that must be truly memorized— dates, artists, chronologies, formulas—there are, unfortunately, no real shortcuts. You just have to keep working with your flash cards until you have no trouble providing the right answer, even after you shuffle the cards into a random order.

Memorization is particularly dependent on your available mental energy. It doesn't work if you try to commit items to memory for eight hours straight, but it does work if you memorize only an hour at a time and only one or two hours a day. So separate the task of memorizing from your other review. Spread the work out over many days, and never dedicate too much time to any one sitting with your flash cards. Melanie from Dartmouth recalls how some of her peers would "review their flash cards at any opportunity—eating dinner, waiting in line at an e-mail terminal," which is the most effective way to get through this tedious task and commit the necessary items to memory.

Step 5 Invest in “Academic Disaster Insurance”

Straight-A students have a knack for avoiding rogue questions. It's as if they invest in some sort of academic disaster insurance: protection against the unexpected return of those obscure topics that slip by when you doze off for a moment in class. In reality, this insurance policy is nothing more than a simple strategy: Eliminate your question marks. This technique can be employed throughout the term and, over time, significantly reduce the chance that you will be baffled by an unexpected exam question.

Eliminate Your Question Marks

In Step #1, we covered smart techniques for taking notes in class. If you remember, this strategy suggests that you put a question mark in your notes for any topic that flies by without you really understanding the conclusion. This will occur occasionally in both technical and nontechnical courses—sometimes as the result of your attention wandering and sometimes as the result of the professor heading off on a tangent and not offering a satisfactory explanation.

These question marks are dangerous. As Christine from Harvard puts it, by skipping a point made in a lecture, “you’re gambling with the possibility of being truly in the dark on the exam.” The scenario is simple. During the semester a few topics slip past your attention in class, so you end up with a handful of question marks in your notes. When it comes time to study, you have more than enough big ideas that you do understand, and that you need to review, so the occasional question-marked topic gets ignored. You enter the exam feeling prepared, and then, as luck would have it, you find yourself face-to-face with a big essay question covering one of those bypassed concepts. Whoops. To prevent this from happening, you need to eliminate these question marks. The key is to start this process well before the exam. If you leave all of these question marks unanswered until you start studying, you will end up spending many extra hours looking up the required explanations. Learning a large quantity of material from scratch during the review process is a mistake made by average students—and you should avoid this. Instead, try to knock off question marks as soon as they arrive. By the time you begin studying you should, as

Robert, a straight-A student from Brown, explains, “have at least a vague understanding of every topic that will be covered on the exam.” The following four tactics, if used regularly, will help you achieve this goal. They provide a solid defense against unclear ideas and will allow you to start the study process with an explanation in mind for all relevant topics.

- Ask questions during class. “When in doubt, I just ask questions in class for more clarification,” explains Worasom from Brown. If a topic slides by you, raise your hand and ask for a clarification. The more question marks you eliminate on the spot, the less work you will have to do later.
- Develop the habit of talking to your professor briefly after class. “Talk to the professor after class, or send him an email asking for clarification about questions that arose during his lecture,” suggests Jason from Penn. There is nothing unusual about this. Most professors will stick around for five or ten minutes after the bell to answer final questions. Take advantage of this time. When the class ends, head over to the professor and see how many of the question marks of the day you can get eliminated. You should then immediately correct your notes before you forget the explanations. Will this turn you into a brown noser? No! The brown nosers are those who come up to the professor only to tell him what parts of the lecture they found interesting, or to offer up some of their own “brilliant” thoughts on the topic. You, on the other hand, have a list of focused questions that you want answered, which makes you seem smart, not snivelling.
- Ask classmates. If you’re still unclear, James, a straight-A student from Dartmouth, recommends that you “talk with other people about the topic.” Send an e-mail or corner them in the hall soon after the lecture. If they understand the topic, it will take them only a few minutes to explain it to you while it’s still fresh in their minds.
- Come prepared to exam review sessions (if offered). Many classes offer a formal review session the week before the exam. Go to these. Before you arrive, jot down all of the topics from your notes that you are still unsure about. Then, during the session, try to get all of them answered. Don’t be worried about having a lot to discuss. More often than not, review sessions suffer from too few student questions, so your professor or TA will appreciate your preparation.

The goal of these defensive tactics is to eliminate your question marks without adding any study time. If, however, despite your best attempts, some of these unclear topics persist until your review, your last-ditch defense is to skim. You probably won’t have time at this

defense is to skim. You probably won't have time at this point to look up detailed explanations from scratch for every leftover question mark. And, even if you did, the effort would be way too time consuming (remember: Straight-A students avoid long study hours), so skim over just enough material to have something to say for each of these points. On the off chance that one of these lingering question-marked topics comes up on the exam, at least you won't leave a blank page. But this situation can still be dangerous, so follow the first four strategies to reduce the topics you don't understand as much as possible before your studying begins.

Step 6 Provide “A+” Answers

Even the most prepared student can bomb an exam due to poor test taking skills. The potential pitfalls during an exam are numerous, but the most common are: (1) running out of time and (2) providing answers that, although detailed, don't fully answer all parts of the question being asked. In fact, these two dangers work together in a devilish counterbalance, making them particularly hard to conquer. That is, if you try to avoid spending too much time on questions, then you are likely to provide time on questions, then you are likely to provide

incomplete answers. On the other hand, if you try to provide detailed answers, then you are likely to run out of time.

The situation sounds dire, but it's not. With the right strategy, you can eliminate these fears and ensure that your grade properly reflects your level of preparation. Straight-A students recognize this point, and when asked about test-taking, they provided detailed responses, proving that for them, this final step is no mere afterthought. They treat the test-taking process with great respect, and this attention is reflected in their consistently high grades. Their advice has been culled into five key strategies. Together, they provide a comprehensive test-taking system, finely tuned through experience to maximize performance. Follow these rules on every exam, and you'll be able to transform yourself into a test-taking machine—cool, confident, and ruthlessly efficient as you move from question to question, providing the best possible answers.

Strategy #1: Review First, Answer Questions Later

“I always read through the entire exam first,” explains Robert from Brown. This is good advice—for any exam, your first step should always be to review all of the questions. If it’s an essay exam or a technical exam with a relatively small number of questions, then read each prompt carefully. If the exam is multiple choice or contains many questions, skim through quickly and get a feel for which topics are covered. This review familiarizes you with the length and relative difficulty of what lies ahead. It also primes your brain for the topics you’ll need to address. “Always scan all the questions,” explains Anna from Dartmouth. “This allows your mind to think about all of them, even while you are focusing on one in particular.” In other words, while you toil away on an early question, another part of your brain, working in the background, will begin to retrieve information relating to the topics still to come. This actually happens, and it helps you answer the later questions more quickly.

Finally, and perhaps most significantly, this first step also helps you relax. Stress proliferates in a classroom right before an exam is distributed. It’s a make-or-break situation. Months of effort have led up to this single moment, and you have only a scant hour or two to prove what you know and secure your final grade. You begin to question yourself. Did you study everything you needed to? Have you forgotten important ideas? What if the to? Have you forgotten important ideas? What if the exam focuses on a subject you know nothing about? If you left it blank, what would happen then? Just thinking about this situation is enough to make most undergrads sweat.

However, by taking the first few minutes to carefully review the exam, you break this mounting tension. It gives you something productive to do that doesn’t involve actually answering questions. Once you complete this task and build a better idea of what to expect, the exam becomes less menacing. You’ve seen the questions, and (hopefully) none seem impossible. You begin to say to yourself: Okay, maybe this isn’t all that bad. Your confidence rises, your heart rate lowers, and your stress begins to dissipate. Now you can turn your full attention to providing standout responses.

Strategy #2: Build a Time Budget

At any given point during an exam, you should know the maximum number of minutes you have to spend on the current question before moving on to the next. As Doris from Harvard puts it: “I lay down very strict time limits for myself on each question.” This strategy goes a long way toward avoiding time trouble; it keeps your attention focused and prevents you from spending too much time on any particular question. The key to maintaining this keen awareness is to build a time budget. First, take the time allotted for the exam and subtract ten minutes. Next, divide this amount by the number of questions. The result is how long you have to spend on each prompt.

What should you do with this information? For an exam with a small number of questions, mark right on the test pages the time when you should begin and finish each one. For an exam with many questions, divide the exam into equal fourths, then jot down the time you should begin and end each section. In both cases, these recorded times will keep you updated on how close your current progress matches your predetermined schedule. Why do we subtract ten minutes in the first step? This provides a safety buffer. You want a few extra minutes available here and there to be able to double check your answers when you are finished, or go back and add more insights to questions on which you were rushed

Strategy #3: Proceed from Easy to Hard

Straight-A students almost never answer exam questions in the order that they are presented. Years of informal experimentation by successful students have demonstrated that the most effective way to tackle an exam is to answer the easiest questions first, and this is exactly what you should do. Start with the most approachable questions before moving on to the more forbidding. Don't worry if this has you skipping around all over the exam—in most cases the provided order is irrelevant. The advantage of this approach is that it first focuses your energy on the questions you know the most about, ensuring that you get maximum points on these. It also gives you a better chance of conquering the more difficult ones. “I always skip a question if it does not come to me immediately,” explains Ryan from Dartmouth. “This keeps my mind clear to answer other questions and hopefully something will jog my memory.” When you come across something hard early on in the exam, your natural instinct is to panic. You have so many more questions to finish, and you can almost feel the minutes ticking away as you stare blankly at this one particular

roadblock. It can be tough to get your focus back to wring out as many points as possible from the easier questions that follow. If, instead, you tackle this same roadblock at the end of the exam, you'll find that the situation seems less dire. You've answered everything else, so all that's left to do is working out this final puzzler. More often than not, you will find the mental block diminished. Without the pressure of other questions looming in the background, you can take a more relaxed approach. You might not know the best answer, but you can spend some time to devise a reasonable answer. Because you have nothing else left to finish, you can spend the remainder of the time polishing this answer, thinking, and repolishing. The result is the strongest possible outcome given your state of preparation.

Strategy #4: Outline Essays

When facing an essay question, don't just start writing and see what happens. This approach leads to rambling answers and missed concepts. Instead, your first step should be to jot down a quick outline. This might seem like a waste of time, but in truth it can be invaluable.

First, reread the question carefully. As Matthew from Brown explains: "Usually, you can isolate three or four mini-questions from a single essay question." Underline each of these mini-questions; this will help you flesh out your outline and avoid an incomplete answer. "Then, outline on paper (not in your head) the way that you will use what you know to answer these mini-questions," continues Matthew. To do so, use the margin of the exam to jot down all of the points you can recall that are relevant to the question. Record only a few key words for each point to save time and space. For example, if you want to mention an argument made by an author named Robert Caro dealing with Lyndon Johnson's views on race relations, you might jot down: "Caro—race." Next, go back and check the question parts you underlined in the first step. Make sure each is adequately addressed by the points you just noted in the margin. When you're sure that you have identified all the relevant information for the essay, number these points in the order that you want to present them. Only now should you begin writing your essay. Follow your outline, and the writing will proceed smoothly. You should be able to quickly produce a solid response that draws on everything you reviewed and addresses all parts of the question asked.

Strategy #5: Check Your Work

Advice and go back and check your work. You will be surprised by how many times this final review turns up a mistake in a technical problem or an important concept that you forgot to mention in an essay. If, after your first round of review, you still have time left over, then go through and check again. If there is a problem you feel particularly shaky on, use this time to go over it in detail, augmenting the answer wherever appropriate. Don't worry about using carets and arrows to add in new phrases and facts to your essays, or to point out added steps in your technical problems. Neatness doesn't count on exams; it's the content that matters. It's tempting to relax after finishing your exam, perhaps walking proudly to the front of the classroom and handing it in before anyone else. But aside from the wistful stares of your classmates, this strategy is ill conceived. Double checking your work up to the last minute can make the difference between an above-average student and an academic star.

Part Two Cheat Sheet

Step #1. Take Smart Notes

- Always go to class and try to take the best notes possible.
- For nontechnical courses, capture the big ideas by taking notes in the question evidence/conclusion format.
- For technical courses, record as many sample problems and answers as possible.

Step #2. Demote Your Assignments

- Work a little bit each day on your assignments; avoid suffering from day-before syndrome.
- Read only the favored sources on the syllabus in detail. To decide how much time to spend on supplemental sources, remember the importance hierarchy: – readings that make an argument are more important than – readings that describe an event or person, which are more important than – readings that only provide context (i.e., speech transcripts, press clippings).
- Take reading notes in the question/evidence/conclusion format.
- Work in groups on problem sets, solve problems on the go, and write up your answers formally the first time.

Step #3. Marshal Your Resources

- Figure out exactly what the test will cover.
- Cluster your notes for nontechnical courses.
- Build mega-problem sets for technical courses.

Step #4. Conquer the Material

- Embrace the quiz-and-recall method. It's the single most efficient way to study.
- Spread out memorization over several days. Your mind can do only so much at a time.

Step #5. Invest in "Academic Disaster Insurance"

- Eliminate the question marks for topics covered in class or from the reading that you don't understand.

Step #6. Provide “A+” Answers

- Look over the whole test first.
- Figure out how much time you have to spend on each question (leaving a ten-minute cushion at the end).
- Answer the questions in order of increasing difficulty.
- Write out a mini-outline before tackling an essay question.
- Use any and all leftover time to check and recheck your work.

Essay and Papers

Paper writing is hard, but the good news is that it doesn't have to be as hard as most students make it. Let's begin by taking a closer look at the paper-writing process itself, which can be broken down into three separate components:

1. Sifting through existing arguments.
2. Forming your own argument.
3. Communicating your argument clearly.

The sooner you dispel the notion that writing is the most important part of paper writing, the easier it will become for you to reap the benefits of the straight-A approach.

Research Papers vs. Critical Analysis

Essays

Writing assignments come in many varieties. Some require a lot of original research, whereas others require only a critical discussion of a topic introduced in class. Some have ulcer-inducing length requirements, whereas others ask for only a handful of pages. We capture these differences with the simple classification scheme of research papers versus critical analysis essays. Some assignments, of course, may fall outside of these two descriptions, but, for the most part, they capture the major variations in paper writing. All of the advice that follows explicitly describes which of these two types it applies to.

Research Papers

A research paper requires you to choose a topic within provided parameters and then devise an original thesis relevant to your chosen topic. For example, the broad parameters for your topic choice might be “anything involving the British Empire,” the specific topic you choose from within these parameters might be “public schools and the British Empire,” and the thesis you choose might be “the public school system in nineteenth-century England had a curriculum specifically tailored to the requirements of the British Empire.”

Research papers require original research to support your original thesis, and, accordingly, their page lengths are long and their due dates are generally a ways off from when they are assigned. If you spread out the work appropriately and choose the right topic, research papers can provide a rewarding intellectual challenge. Proposing and supporting an original argument is exciting. However, if left until the last minute, these assignments can become a nightmare. More than a few students have suffered a nervous breakdown from the stress of tackling a major research paper at the last moment. So for these assignments in particular, take careful note of the scheduling recommendations that follow.

Critical Analysis Essays

Critical analysis essays are the bread and butter of most liberal arts classes. These essays are short, and they typically require you to analyze one or more of your class reading assignments. They are often set up as a comparison, for example: “How do Nordlinger and Hopkins differ in their approach to understanding American Isolationism. What cultural and theological sources account for these differences?” Critical analysis essays differ from research papers in several significant ways: Topics are provided in advance, your thesis is nothing more than a specific answer to the question asked in the assignment, and there is little-to-no original research required. Not surprisingly, these essays require less time to complete than research papers. Their goal is to test your understanding of the material presented in class, not to seek out and present new ideas. Don’t get the wrong idea—these essays are not necessarily easier than research papers. College writing assignments follow a simple rule: The required precision of your thinking works in direct proportion to the constraint of the material. That is, the more specific the assignment, the more subtle and detailed your thinking must be. So beware. If your assignment covers only one chapter, then you’re going to need to understand every word of that chapter and be able to articulate your analysis with precision.

Step 1 Target a Titillating Topic

Remember: A topic does not equal a thesis. A topic describes an interesting subject or area of observation. A thesis presents an interesting, specific argument about that subject or observation. Let's look at some examples. As mentioned, for a critical analysis essay, the topic is provided, so this step won't be applicable. For a research paper, however, you get to choose the topic—so we'll focus on the specific case of research paper topic selection for the remainder of this section.

Choosing a Research Paper Topic

Typically, the professor will provide some loose parameters. For an art history course, these might be: parameters. For an art history course, these might be: "Any artist covered in the class so far." For a political science class they might be: "Economic policy and Latin America." The key is to choose a topic, within the constraints of the assignment, that excites you. All work that follows on your paper will stem from this topic; if you are not intrigued by the idea, then the paper-writing process will be tedious. If, on the other hand, you are fascinated, or at least curious, then the process will be that much easier. The best way to identify a titillating topic is to start looking for one early. "I work on topic ideas in my head and on scraps of paper beginning anywhere from a week to a month in advance of the actual deadline for a paper," explains Doris, a straight-A Harvard student. Follow this approach. On the very first day of class, read the description of the research paper(s) that will be assigned. The syllabus should describe each paper's topic parameters, and the professor will usually discuss these assignments briefly early on in the term. Once you know the parameters for the paper, you should constantly be on the lookout for a particular subject or observation that interests you. If one reading assignment really grabs your attention, jot down the topic so you'll remember it later. If a professor poses an interesting question during class, or piques your curiosity by describing a compelling open area of research, make a note of it. As Sean, a straight-A student from Yale, explains: "Keep an eye out for concepts that interest you in the readings and lectures. If there's something that grabs you, it will probably make a good topic." If you have trouble finding a topic in advance, you have two options. First, as Chien Wen, a straight-A student from Dartmouth, advises: "Approach your professor with some ideas you have and let him recommend some appropriate readings." Professors know their field well, so they should have no trouble pointing you toward some resources to help flesh out your initial thoughts. Second,

as Chien Wen also advises: “Read your primary sources carefully.” Grab a textbook or similar general source from the class, and then skim through and look for angles that catch your attention, passages that make you ask “why,” or descriptions of competing arguments debating an interesting subject. “Be imaginative and intuitive—look for unusual connections between individuals, ideas, and broader themes,” says Chien Wen. In general, the more care you take during this first step, the easier the rest of the paper-writing process will be, so take your topic choice seriously.

Step 2 Conduct a Thesis- Hunting Expedition

You need to construct a thesis that makes a compelling argument concerning this topic. Once again, for a critical analysis essay, most of the work toward constructing your thesis has already been done for you. Typically, the essay prompt will contain a specific question (i.e., “How do the two arguments differ?” or “Why does the author say this?”), and your thesis is a summary of your answer. For a research paper, on the other hand, you might be dealing with a very broad topic that requires significant digging to find an interesting and supportable idea that can be expanded to fit the required page limit. In both cases, some initial research is required. A thesis devised from scratch is dangerous. Without some initial exploration, you have no idea whether or not your idea is viable, and there are few experiences worse than being forced to restart a paper after many hours of work. At the same time, however, you don’t want to dedicate days to intensively reading every book in the field in search of a perfect thesis, because this would be inefficient. For a critical analysis essay, the solution is simple: Review both the reading notes and lecture notes that relate to the essay prompt. And that’s it! This should provide a rough idea of how you are going to answer the question posed by the assignment. Therefore, your thesis has been found. Even though it’s simple, don’t skip this step for critical analysis essays. The earlier you develop an idea of what you are going to say, the more time you have to refine the nuances of your argument. For research papers, on the other hand, the task of finding a thesis is more complicated. No sources have been preselected for you, and no specific question has been provided. All you have is a general topic that you thought up yourself. Now you must wade into a vast sea of knowledge and somehow find enough material to devise a strong thesis—while avoiding drowning in the sheer volume of available information. Not surprisingly, the straight-A students interviewed for this book have mastered the art of conducting research paper thesis-hunting expeditions. Their goals are twofold: (1) find an interesting thesis that can be supported within the scope of the assignment; and (2) minimize the time required to conduct this search. Accomplishing both of these goals sounds hard, but straight-A students get it done. What’s their secret? One simple phrase: Start general, then move one layer deep. Let’s take a closer look at what this really means. Start General, Then Move One Layer Deep “I usually begin with basic sources,” explains Chris, a straight-A student from Dartmouth. “If I’m doing a paper on the Kurds in Turkey, for example, I get a recently published general history on this topic.” Similarly, if your topic is Faulkner’s early writing, you might find one or two Faulkner biographies and then focus only on the chapters dealing with his early years. If you have a

hard time finding a few general sources for your topic, then ask your professor—he'll have plenty of titles to recommend. In addition, keep in mind that most courses set up a reserve shelf at the campus library. This shelf contains books that were selected by the professor because of their relevance to the course. Typically, you can check out reserve books for only a couple of hours at a time, so they should always be available to the students who need them. This is a great place to find general sources. So that's step one (the "start general" part of the strategy). The reason we need a second step is because you shouldn't expect to find your thesis idea in a general source. Of course, you might get lucky and find an interesting thesis during this first step. In general, however, overview sources will be much too broad to reveal a targeted and interesting argument that hasn't already been written about extensively. The main reason you found these general sources is to get at their bibliographies. As Chris goes on to explain: "I read any chapters from my general sources that look useful for my paper. I then look up the sources used in that chapter." In other words, the second step of your thesis-hunting expedition is to examine the list of books and articles cited in the relevant sections of your general sources. From this list, choose the cited works that look the most promising, and then go find them in the library. These sources will be more focused—perhaps journal articles or books addressing only a small number of specific arguments. You are most likely to come across an interesting and appropriately targeted thesis idea using these more focused sources. Let's apply this approach to our Faulkner example from before. Perhaps one of our general sources cites a journal article on the influence of a specific European modernist writer on Faulkner. You find this journal article, and while reviewing it you notice that it mentions, in passing, a list of other modernist writers who might have had a similar influence. Aha! Now this could be an interesting thesis. You might choose one of these modernists from the list and then look for historical evidence of their connection to the primary writer. Perhaps, instead, one of the general sources talks about a period of Faulkner's life that he spent in Europe. Maybe it also mentions that our only records of this travel are letters written by the young author himself, and then it provides a citation to a collection of these letters. You then locate these letters, begin to read through them, and notice that he mentions a particular bar in London several times. This too might be a source of a fascinating thesis. You could investigate the intellectual climate of London nightspots of the time and posit their potential influence on Faulkner's work. From there, perhaps the core of your paper could be to present a piece of writing from right before the trip, and another from right after, and then argue which stylistic changes may have been influenced by his foray into the intellectual intensity of the London literary milieu. The key is to keep in mind that even very small observations can

lead to large, interesting discussions. How do you know your thesis idea is good enough to support an insightful paper? “A great thesis typically has at least these four qualities,” explains Christine, a straight-A student from Harvard. “It’s provocative, nuanced, direct, and inclusive.” She goes on to warn: “A thesis should, at the same time, also show a grasp of the complexities of a subject—‘in this poem, X symbolizes Y because Z’ is a weak type of thesis structure, far too reductive and simplistic—don’t be afraid to leave room for ambiguity and unresolved issues.” Wendy, a straight-A student from Amherst, puts it simply: “The most important part of your paper is the thesis. Once you have a solid thesis, the rest just falls into place.” Here’s the tricky part: Your thesis will change and evolve as you continue the paper-writing process. This is inevitable, because you haven’t done your exhaustive research yet. At this early stage, your thesis more likely explains the type of connection or answer you hope to find, rather than the final connections and answers themselves. To revisit our Faulkner example, your early research may indicate that the social milieu of a certain London nightspot influenced a young Faulkner, but you might not yet know all the ways this influence was manifest. More research is required, and that’s okay. You should embrace this evolution of your ideas as the process continues. For now, it’s sufficient that your fledgling thesis looks like it’s on the path toward fulfilling the properties mentioned above. In other words, before continuing, make sure that your preliminary research strongly indicates that something similar to your thesis idea will be supported by the more detailed investigations to follow. Be honest with yourself: If you made up your thesis simply because it sounded cool, but have no real reason to believe it to be true, then you’re courting a paper-writing disaster. If, on the other hand, several pieces of early evidence point to the types of interesting connections described by your thesis, then you’re on the right track.

Step 3 Seek a Second Opinion

At this point you should have an interesting topic and a targeted thesis. You're well on your way toward a standout paper, but don't get too far ahead of yourself. It's time to take a step back. More than a few students have dived deep into the paper-writing process, supported by what they thought was a compelling thesis, only to find out many pages later that their premise was not as strong as it initially seemed. Perhaps they fail to find enough evidence to support the argument. Perhaps they stumble across another source that has already made the exact same point. Or, as is often the case, perhaps they find their thesis to be too broad to be succinctly argued within the scope of a paper assignment. The thesis-hunting tips of the last step help eliminate this possibility, but they're not enough by themselves. Once you think you have a good thesis, a final step remains before diving fully into the research and writing process. As Rielle, a straight-A student from Brown, explains: "I often talk to a professor to clarify my ideas before I begin writing." This is great advice. For every research paper and significant critical analysis essay (i.e., assignments more than just a few pages long), you should make a habit of discussing your targeted thesis idea with your professor. Go to office hours, or make an appointment, explain your topic and thesis, then ask the following questions:

- 1. Is my idea appropriate for the assignment?*
- 2. Does it cover too much?*
- 3. Is it too simple?*

For a critical analysis essay, if the professor deems your thesis appropriate, this is a good sign that you are not going to get stuck. You can now move ahead with confidence. For a research paper, if the professor deems your thesis appropriate, take advantage of this time to explain some of the sources you plan to examine. The professor will likely have some additional sources to suggest. Write these down. This just saved you some suggest. Write these down. This just saved you some serious research time! For both types of papers, if the professor isn't enthusiastic about your thesis idea, then he or she will likely help you adjust it into something that is reasonable. When you leave this meeting, which should require only ten to twenty minutes, you will have confidence in the foundation of your paper. You can now move full speed into the research stage without fear of reaching a devastating dead end later on in the process. It's amazing how many students ignore this incredible resource. One simple meeting can make the difference between a standout work and an incoherent dud. Remember, this step is not intended as a shortcut. If

you skipped the previous step and show up at office hours without a targeted idea, the professor is not going to give you one for free. However, as Christine from Harvard explains: “They’ll rarely refuse to listen if they see you’ve thought things out in advance.”

Step 4 Research like a Machine

Not surprisingly, research is the domain of the research paper. For a critical analysis essay, your sources are already specified, and there are probably only one or two of them. Therefore, when working on an essay, you can skip this step and move on to Step #5 (Craft a Powerful Story), which describes how to organize your argument. For research papers, however, the following advice is crucial. Why? Because how you research can make or break your paper-writing efforts. If your strategy is haphazard—as is the case with most students—then two immediate problems will arise. First, the writing process will become frustrating and tedious, since you will be forced to continually stop and seek out new sources to extend your argument. Second, and more important, the resulting paper will be weak. A good argument requires a solid grasp of all relevant information. You want all the necessary facts and ideas to be at your fingertips, easily manipulated, sourced, and shuffled, as you build your case. If your sources are incomplete and disorganized, then your paper will be, too. On the other hand, you can also run the risk of spending too much time on research. Many eager students have succumbed to the horrors of research recursion syndrome—an unhealthy need to go find “just one more source,” often leading to hours and hours of wasted time, dorm rooms overwhelmed with teetering stacks of books, and one seriously sleep-deprived student. This is grind territory, and you should avoid it at all costs. So while at first glance it may seem easier than choosing a thesis or writing the paper itself, in fact the research step of paper writing is easy to get wrong. Fortunately, straight-A students have figured out a way to walk the research tightrope—getting the information they need without becoming lost amid the endless available sources. Their strategy can be summarized by a simple phrase: Research like a machine. They follow a system—a mechanical process, the same for every paper—that produces consistent high-quality results. Feed them a thesis, watch their wheels turn, and then out pops a set of photocopied, organized, and annotated notes. Their system ensures that the quality of their research is sufficient to fuel a standout paper and at the same time requires the minimum amount of time to achieve this goal. Sounds pretty cool, right? But how does it work? Their system is based on these four steps:

1. *Find sources.*
2. *Make personal copies of all sources.*
3. *Annotate the material.*
4. *Decide if you're done. (If the answer is “no,” then loop back to #1.)*

That's it. The devil, of course, is in the details. So let's take a closer look at what each of the steps entails.

1. Find Sources

There are two types of sources: general and specific. As described in Step #2, the former include overviews of your topic (i.e., biography or textbook), whereas the latter focus on specific arguments (i.e., a journal article or book about a specific event or idea). For a college-level paper, most of your best information is going to come from specific sources. The hard part, of course, is finding them.

Step #2: Start with general sources and then look in their bibliographies for more targeted resources.

As David, a straight-A student from Dartmouth, says: "Once you have two or three materials that you like, it's all about the bibliographies...find out where the author found the fuel for his arguments and go check those out." In Step #2, I suggested that you ask your professor or browse the course reserve shelf to find some of these general sources. Another place to look is your library's online card catalog. This sounds obvious, but using an online catalog correctly is not a trivial task. Just typing in keywords might not turn up every book that deals with your topic of interest. You need some more advanced tricks. One such trick is to take advantage of the Library of Congress (LOC) topic classifications. What are these? The Library of Congress tries to classify all books into one large hierarchy of topics. For example, Heinrich Harrer's fascinating book *The White Spider* (an account of the first team to ascend the infamous North Face of the Eiger Mountain) is described by the following two classifications:

1. Mountaineering—Switzerland—Eiger—History

2. Eiger (Switzerland)—Description and travel

When you find a book in an online card catalog, its corresponding LOC topic classifications should be listed. The cool part is that these topics should also be hyperlinked. That is, if you found an entry for *The White Spider*, you could click on Mountaineering—Switzerland—Eiger—History to return a list of every book in the library under this classification. Therefore, if you find one general source on a topic, then you can easily find many others. And once you have found general sources, you can turn to their bibliographies to find something more specific.

The second strategy for finding specific sources is to search for them directly. This approach is important. Not every specific source relevant to your thesis can be found in the bibliography of a general source. This is particularly true for more recent scholarship. Books take a long time to write; if a paper was published only within the last few years, it is

probably too soon to find a general tome that cites it. The problem here is that specific sources can be difficult to find. For example, continuing with the Eiger topic introduced above, let's say your thesis within this topic is: "The many failed attempts to ascend the North Face of the Eiger played an important role in the development of Swiss cultural identity during the first half of the twentieth century." Finding a general source about the Eiger, such as *The White Spider*, is easy enough. But finding a targeted source on the impact of the Eiger on Swiss cultural identity will be significantly more complicated. Simply typing "the impact of the Eiger on Swiss cultural identity" into the library card catalog probably won't turn up many hits. So how do you locate these elusive specific sources? There are four main search tactics.

Search Tactic #1: Break Up Your

Query into General Chunks If you can reduce your specific query to a group of related, yet succinct, general searches, you will have a much better chance of finding a relevant source. Following the Eiger example, you might try:

- Alpine hiking Switzerland culture
- Switzerland cultural identity
- Alpine hiking
- Mountaineering Switzerland

Any one of these more general queries could turn up a source that either directly references your thesis or makes a point that supports your thesis. With practice, you will get better at constructing these general probes aimed at illuminating a specific idea.

Search Tactic #2: Use Journal Databases

As mentioned, specific sources are more likely to be scholarly articles than books. Your library card catalog does not index articles. Therefore, as Chris from Dartmouth recommends, you should consider "article database searches (like JSTOR) on the specific topic." How do you find these databases? Your library Web site should contain a list of available electronic resources. At some point during your freshman year, you will probably be given an orientation on this topic. (Even if you sleep through it, as most of us do, it shouldn't be that hard to figure out.) This list of resources is usually broken up by academic concentration (i.e., Political Science, Anthropology, and so forth). Go to the concentration relevant to your paper, and you should see a list of searchable archives. Many of these resources will be databases of scholarly articles, so search these focused

databases using the general search term chunks described in the preceding tactic and see what pops up. If your topic is interdisciplinary, meaning that it draws from multiple academic concentrations, follow Chris's advice and try a big database like JSTOR (<http://www.jstor.org>), which contains scholarly articles on a large variety of academic topics.

Search Tactic #3: When in Doubt, Google

"Google is your friend, first and foremost," says David from Dartmouth. This is good advice—as Google is a great tool—but it should be used with some caution. A good rule of thumb is: Don't cite Web sites. Academics don't trust them. Journal articles go through extensive peer-reviewing before they are published, and academic books are written by experts and rigorously edited. On Web sites, however, anything goes. Therefore, they're worthless in terms of supporting an argument. Referencing Web sites is something you do in high school. If you do this in college, be prepared to experience the wrath of your professor. This being said, Google is still immensely useful. Not for finding Web sites to cite, but for finding Web sites that reference books and articles relevant to your thesis. For example, a search for "Eiger and Swiss Cultural Identity" might actually turn up some Web sites dealing with, or related to, this obscure issue. The Google search algorithm is a lot smarter than the one used by card catalogs, so even very complicated queries can turn up surprisingly accurate results. If you're lucky, some of these Web sites will mention specific sources—a book name or article title. Now you can look up these in your card catalog, and then treat them like any other formal source.

Search Tactic #4: Ask a Librarian

Most college libraries are staffed with reference librarians who want nothing more than to help you find the information that you seek. It's what they're paid to do, and they're great at it. Too many students, however, ignore this wonderful resource. Here you have experts who can save you hours of struggle by conducting advanced searches on your behalf; yet most students never think to take advantage of the opportunity. Making a visit to the reference desk should be one of your first steps when researching a challenging assignment. Simply explain your topic and thesis to the librarian, and he or she will walk you through several searches. Not only will this identify some specific sources that you may have otherwise missed, but it will also expose you to new library resources and databases that you can now use for future projects. The more time you spend with reference librarians, the better you will become at finding solid material on your own.

2. Make Personal Copies of All Sources

How you handle the sources makes a big difference in the overall efficiency of the paper-writing process. Though there are many ways to deal with the book chapters and articles relevant to your research efforts, many of the straight-A students interviewed for this book favored the following strategy: Make a photocopy or printout of all relevant material. If you find a book that has two chapters related to your topic, photocopy those two chapters. If you find an important journal article, photocopy the entire article. If you find an article online, or a relevant Web site, print it out. The goal is to create your own personal hard copy of all sources. The advantages of this approach are numerous. First, these hard copies are portable. It's easier to carry around a stack of photocopies than a stack of books and journals, so you can take your research with you to your secret study spots or office hours. Second, the information is more accessible. No flipping through big tomes or searching your computer hard drive; all the relevant information is stored in one condensed stack. You can now physically organize your sources, for example, by putting them into piles by author, clustering relevant arguments together with paper clips, or dividing them into folders labeled by subject. As Sean, a straight-A student from Yale, explains: "It's often easier to grasp something when you have a hard copy in front of you." Third, you can mark them up with impunity. "Printouts and Xeroxes of source info are often superior to books or digital copies," explains Christine from Harvard, "since you can annotate them to death." Feel free to underline things, highlight, draw arrows, cross out sections, or put big stars next to important points. In general, this approach maximizes the control you have over your information, ensuring that your sources work for you. However, there are a couple of important caveats to remember. First, make sure you label each photocopy with all of the information needed to later construct a formal citation. For example, if you photocopy a book chapter, jot down on the first page the name of the book, the author(s), the publisher and its location, and the copyright date. Or, if you prefer, follow Christine's advice and simply "make a photocopy of the title and copyright info" as found in the front of the book, so you can use it later while constructing the works cited for your paper and ensure that you don't find yourself "running back to the library at the last moment for citation info." Second, photocopy each source's bibliography. This way, if you come across an interesting reference in one of your photocopies, you will have easy access to the full citation attached to the reference. For articles, the bibliography is almost always listed immediately following the article. For books using the endnote format, you might have to flip to the back to find the bibliography for a specific chapter.

3. Annotate the Material

Finding a source, of course, is just the first step. A stack of photocopied pages is worthless if you don't know what information it contains and how it might be useful to your paper. You need to review the sources and annotate them with a concise description of the important information, if any, that they contain. Be careful how you proceed here. Your first instinct might be to follow the advice described in Part Two about how to take notes on your reading assignments. Don't do this—it's overkill. For now, you should be content to follow the advice of David from Dartmouth, who recommends **that you “skim, skim, skim.”**

Use The Following:

A. Skimming:

I. Step 14-Intelligently Skimming Through The Book. Pages 46-50.

B. Entertainment

I. Method 1-Speed Reading. Pages 58-63.

C. Methods for Basic Knowledge For Deep Work or Bible Study.

I. Method 1-Survey, Question, Read, Recite, Record, Reflect (SQR4). Pages 65-66.

II. Method 2-Use 80/20 Principle For Reading. Pages 67.

III. Method 3-Preview, Question, Read, Summary,Test (PQRST). Page 68.

IV. Method 4-Flip Through Pages and Analyse. Page 69.

V. Method 5-Devotional Bible Study by Using Devotional Books. Pages 70-71.

VI. Method 6-Devotional Bible Read. Pages 72-73

Specifically, read through the source quickly. Every time you pass by an important definition, idea, or opinion that seems relevant to your thesis, jot down (on your computer or by hand) the page number and a quick description. For example, if the author argues a particular point of interest, write only what this point is— there is no need to also copy down the evidence he uses to support it as you would for notes on a reading assignment. If the source is a book, then, as Anna from Dartmouth explains: “Pick out only the chapters that relate to the specific aspect of the topic that you are interested in...it is not necessary to read the entire book!” When you're finished, staple your annotations to your personal

copy of the corresponding source. In general, proper source annotations should act as concise pointers, containing just enough information to show you where the relevant arguments are hiding. In the next step, where you organize all of your gathered information into a coherent structure, these simple annotations turn out to be exactly what you need to quickly assess the importance of each source. Therefore, you will end up needing to carefully read only the passages that help your paper. You should not think of this step as adding work. As you will soon discover, these concise annotations are actually going to save you a significant amount of time.

4. Decide If You're Done

There is no simple answer to this question. While it would be nice to offer a perfect formula for how much research is enough, it is impossible—there are just too many variations to contend with. Some short papers might require dozens of sources, while some long tracts may focus entirely on a handful of original documents. What follows is a rough procedure that should aid your decision about whether or not you have gathered enough research. Remember, this is just an approximation. Always keep in mind the context of your specific assignment. However, this approach should help reduce the guesswork involved in completing this step.

The Research Termination Determination Procedure:

1. List the topics (specific questions, facts, or accounts from your research) that are crucial to support your thesis.
2. List the topics that might help you support your thesis.
3. If you have at least two good sources for each of the topics from #1, and have at least one good source for a majority of the topics from #2, then you're done. Otherwise, you need to keep researching.

The reason these criteria are just an approximation is because at this early stage you probably don't know exactly how your thesis argument will proceed, so you don't know exactly what information you need. This procedure simply helps you estimate as best you can. By separating out the crucial from the potentially helpful, you are less likely to get stuck hunting down an obscure piece of information that you could do without. This approach is advised by David from Dartmouth, who describes the following similar procedure for sorting his research sources: "I make three piles of my sources: very useful,

potentially useful, and not useful.” To draw from our previous example, if your thesis deals with the Eiger and Swiss cultural identity, you might construct your list of “crucial” and “might help” topics as follows:

1. Topics that are crucial to support the thesis:

- Basic historical information concerning the Eiger (when it was discovered, when it was first climbed, and so forth)
- Arguments concerning Swiss cultural identity at the turn of the century

2. Topics that might be helpful in supporting the thesis:

- Memoirs of people who were involved in the first ascents of the mountain
- Press accounts from the time (both Swiss and non-Swiss)
- General discussions of the role of sports and national pride

If you have a hard time tracking down one of the topics from the second list, you would still be okay. If, on the other hand, you have a hard time tracking down either of the topics from the first list, then you need to keep looking. In the next step, where you actually begin to outline your paper, it's expected that you might need to return briefly to the research phase and find additional sources to fill in any holes. If you follow the procedure above, however, you will minimize the amount of secondary research that you are forced to conduct—thus saving yourself from more hours in the library.

Step 5 Craft a Powerful Story

This step is where the magic happens. It's the fun part of paper writing—the moment of intellectual eureka. You have already defined (and verified) a compelling thesis, and you have at your disposal a collection of well organized and annotated research material. Now it's time to stretch your mental muscles and pull these pieces together into a powerful story. As Anna from Dartmouth says: "In order to write a great paper, you really need to make connections that other people haven't made, and the only way to do that is to think." This is the step where such thinking occurs.

Formulate Your Argument

"You must have a vision of what the overall structure of your paper will be," explains Frank, a straight-A student from Brown. "Organization of thought can make a decently researched essay into a fine piece of academic work." Formulating a solid argument, however, cannot be reduced to a system; it is a mental exercise that requires critical thinking and creativity. At the college level, there is no set structure that allows you to fill in the blanks and automatically produce a smart paper. As mentioned in the opening to Part Three, the intro, body and conclusion nonsense introduced in high school won't do you any good here. It's too simplistic, and your professors will be expecting more. In general, a good college-level argument should accomplish the following:

- 1. Draw from previous work on the same topic to define the context for the discussion.**
- 2. Introduce a thesis and carefully spell out how it relates to existing work on similar issues.**
- 3. Support the thesis with careful reasoning and references to existing arguments, evidence, and primary sources.**
- 4. Introduce some final prognostications about extending the argument and its potential impact on the field as a whole.**

There is, however, no set order or format for presenting these general points. One paper might start by defining the context and then move on to the thesis. Another paper might start with the thesis, argue it, and then introduce the broader context at the end. Many papers might interweave all four points. There is no right answer here. And the hard truth is that the only way to get better at organizing and presenting your thoughts is through practice. So write a lot and read good arguments a lot. This is the best recipe for

developing your skills for this step. That being said, there are some general pointers about how to go about formulating your argument. These aren't rules for what to say; rather, they are tips for how to get your brain fired up and your creative juices flowing.

Tip #1: When it comes time to craft the storyline of your paper, put yourself in the right mind-set. Grab a copy of Atlantic Monthly, The New Yorker, Harper's, or any other publication that features well crafted discussions. Peruse some articles, and then go for a walk along a quiet path. Alternatively, as David from Dartmouth recommends: "Talk to friends —if they are good friends they will allow you to bounce ideas off of them and talk through your work." You can also cloister yourself in a dusty, wooden-shelved, overstuffed-armchair-filled corner of the library, or argue with your professor during office hours. Reread related articles and chapters from your course syllabus. Watch a PBS documentary. Do whatever it takes to get the reasoning portions of your mind inspired and curious.

Tip #2: At this point, grab your source material from the previous step. If your assignment is a critical analysis essay, this will consist of only a couple of books and your reading notes. If it's a research paper, you might have a large stack of photocopied chapters and articles. In either case, dive into this information, and start letting the relevant facts and arguments settle into your mind. This is where your annotations will point you toward what's interesting, and help you avoid the irrelevant.

Tip #3: Take a break. Do something else. Let the pieces float around in the background noise of your mind. "The first thing I do when I have a paper to write is take a nap," explains Laura, a straight-A student from Dartmouth. "I crawl into bed and just think...as long as I'm thinking about the subject when I fall asleep, I will dream about the material and usually come up with some sort of interesting idea." Similarly, start looking for any opportunity to do a little thinking about your argument. "I think about my paper when I go around completing my daily chores, when I walk to class or when I wait on line in the dining hall," explains Anna from Dartmouth. Use this downtime to slide the pieces of your argument around in your head and play with the structure a bit. Keep returning to your research material as needed to find more details and to increase your understanding. You need to

expose yourself to the source material again and again to fully internalize it. Only then can you really pull together the best possible argument.

Constructing an Outline

You need an outline to capture the argument you just spent so much time devising. Keep in mind, however, that all outlines are not created equal. In fact, there are two major outline-related mistakes made by students.

First: under-outlining. If your outline lacks enough detail, it's not going to serve its purpose as a structure to guide your writing, and you will end up writing from scratch. You want to avoid this at all costs; it leads to argumentative dead ends and weak structure overall. "In high school, I wrote all my papers in one go, starting with the intro, constructing and polishing each sentence in order," explains Christine from Harvard. "In college I've become a huge fan of outline-based writing, which has made my essays much more tightly argued and given them better, clearer trajectories...since I can now shuffle topics around until they flow with some natural order and logic— rather than straining rhetorically to bridge from one idea to another."

The second mistake: over-outlining. Some students construct beautifully intricate outlines, replete with three or four levels of information, roman numerals, digits, letters, and tabs flying everywhere—the type of outline they taught you to make for your fifth-grade research project. Don't do this either. It constrains you. As Doris from Harvard explains: "One pitfall to avoid is getting stuck in the outline stage—I've seen students who spend far too much time embellishing their outlines when they should really have begun writing the paper itself long ago." When it comes time to write, you will be hampered if you constructed an outline that practically spells out what each sentence of each paragraph should say. These sorts of low-level decisions should be made when you write, not before. It's not until you're actually putting words on paper that you will understand the best way to make each small piece of your argument flow. Don't let an outline make these decisions for you. The happy medium between these two extremes is to construct a topic-level outline. Before we can cover the specifics of this process, I must first define what I mean by "topic." Here, I use the term to describe any self contained point that you might discuss in your paper. Typically, this is something more general than a piece of evidence but also more specific than a multipart argument. For example, here are some sample topics for our hypothetical paper about the Eiger:

- Our thesis about the Eiger and Swiss cultural identity
- Early written accounts of the Eiger

- The first ascent of the Eiger
- Contemporary press accounts of Eiger summit attempts
- Mentions of the Eiger in early-twentieth-century popular culture
- Mentions of the Eiger in early-twentieth-century Swiss tourist brochures
- MacMillan's thesis about the Alps and European identity
- The relationship between our thesis and MacMillan's argument
- Concluding thoughts about our thesis—implications and future work and future work

We start the outlining process by constructing a topic skeleton. This is a list of all the topics you will discuss in your paper, presented in the order that you plan to include them. Type this list directly into your computer because you will later need the ability to insert text in between items. Your topic skeleton succinctly describes the structure of your argument. For example, we might take the previously mentioned topics and order them as follows to form a topic skeleton for our hypothetical Eiger paper:

1. Mentions of the Eiger in early-twentieth-century Swiss tourist brochures
 2. MacMillan's thesis about the Alps and European identity
 3. Our thesis about the Eiger and Swiss cultural identity
 4. Early written accounts of the Eiger
 5. The first ascent of the Eiger
 6. Contemporary press accounts of Eiger summit attempts
 7. Mentions of the Eiger in early-twentieth-century popular culture
 8. The relationship between our thesis and MacMillan's argument
 9. Concluding thoughts about our thesis—implications and future work
- At this point, no specific pieces of evidence are described by our outline, but it does capture how the paper will flow. In a perfect world, you would have at least one or two good sources to support each topic.

However, it will often occur that as you formulate your topic skeleton, you come across a topic that you really need to include but for which you don't yet have any sources. That's okay. We mentioned at the end of the last step that once you start formulating your argument, you might come across some holes that need to be filled. This is exactly where these holes will become noticeable. Once you have completed your topic skeleton, you need to return to the previous step and find sources to support any of the currently unsupported topics. If you followed the research termination determination procedure from before, there shouldn't be too many of these holes.

Filling in the Details of Your Topic Outline

Once you finish your topic skeleton, and find sources for all of the unsupported topics, it's time to fill in the supporting details. This next step is crucial. As Christine from Harvard explains: "Below each bold header [in my topic skeleton], I compile in regular typeface the evidence pertaining to that header." You should actually type quotes from your research material right into the word processor document containing the outline, and label each quote with the source and page that it came from. For example, under the "first ascent of the Eiger" topic from above, you might insert quotes from a few different books on the mountain as well as excerpts from several contemporary articles. Some of these latter excerpts may also be included under the "contemporary press accounts of Eiger summit attempts" topic. It's okay to share information between topics at this point, since you will sort out which quote to use where once the writing process begins. This is not a time for caution—if it seems relevant, stick it in.

At first, this step may sound excessive. By the time you finish, your outline will be large and filled with quotes, perhaps even longer than the projected length of your completed paper. Fortunately, this process is greatly simplified by the format of your gathered research materials. Because you made a personal copy of and annotated every source, finding the appropriate pieces of evidence to include in your outline will be much easier than if you had to page through each book and article from scratch. Furthermore, the benefits of this outline far outweigh the annoyance of constructing it. As Robert, a straight-A student from Brown, explains; "I find that using this process helps me avoid digging through a pile of books and articles for each piece of information I need as I need it during writing." Remember, the goal of the straight-A approach is to separate the different components of paper construction. When it comes time to write, you don't want to be flipping through your sources, hunting down the right support. This drains your energy, increases your pain, takes time, and reduces the quality of your writing. This is why it is crucial that you extract the information from your sources in advance. Later, the writing process will be reduced to the much simpler task of simply building a framework around this already identified and organized information structure.

Step 6 Consult Your Expert Panel

"I discuss ideas with friends," says Suzanne, a straight-A student from Brown, "and am therefore usually pretty confident with my argument by the time I sit down to write." Suzanne reinforces a key observation: The more input you receive, the better your paper will turn out. And because soliciting advice is easy, you might as well get your outline reviewed by a group of people you trust. In the straight-A lexicon, this strategy is called "consulting your expert panel." The technique is popular because it requires little effort on your part, but the impact on your paper quality is significant. This is the final push that transforms your thinking from interesting into compelling and your paper from competent into a standout.

Choosing Your Expert Panel

The size of your expert panel should be directly proportional to the importance of the assignment. If it's a one-page essay worth 5 percent of your grade, then your expert panel should consist of only yourself. If it's a medium-size critical analysis essay, you might aim for two opinions. If it's a major term paper worth a significant portion of your grade, then you may want to solicit feedback from as many as half-a-dozen well-chosen people. Who should sit on your panel? Your number one pick should be your professor. Unless he specifically states that he won't discuss drafts in progress (which professors sometimes do to avoid an overload of conferencing in a large class), definitely plan to bring your outline to office hours. Lay out the general shape of your argument, and the types of sources you are drawing from and where. More often than not, the professor will have some targeted advice on how to better present your points. He might suggest a new order or an added topic that should be addressed. As David from Dartmouth notes, this meeting also "will help you to create a rapport with the prof, and give you an idea of what he or she is looking for." Yes, you've already talked with your professor in Step #3 (Seek a Second Opinion). Don't worry. There is nothing wrong with talking to a professor on two separate occasions for one paper. The first conference was quick and dealt with making sure you were starting off in the right direction. This second conference is more detailed, making sure that you managed to stay on course. Keep in mind that some students talk to their professors many times during the paper-writing process, perhaps once or twice a week. This is overkill and shouldn't be necessary if you've followed the efficient strategy laid out in this book. But rest assured that two visits are hardly monopolizing your professor's time. In addition to your professor, as David also suggests, "if you have smart friends, get their help too."

Friends from the same class are your best bet, since they will already understand the constraints of the assignment. If you aren't close with any classmates, then tap a friend with a compatible academic background. For example, if your paper is for a history class, it makes more sense to talk to a liberal arts major than an engineering major. The former will be more familiar with this style of paper. Pick a half-hour period to sit down with each friend you chose. Explain your thesis and then run through your outline, touching on your main supporting arguments. Your friends will help you identify pieces of your structure that are unclear or unnecessary. As Jason, a straight-A student from the University of Pennsylvania, explains: "If you can explain why your argument works in a rational, step-by-step manner, and you have an arsenal of sources to cite to support the argument, then you're ready to go." One final warning: Before discussing with a classmate, make sure that collaboration of this sort is allowed. It should be no problem for research papers, but for focused critical analysis essays the professor may specifically forbid that you discuss your response with other people from the class.

Step 7 Write Without the Agony

If you've followed the Straight-A strategy so far, writing should be the most straightforward part of constructing a standout paper. This step is not mysterious. At this point, you know what to say and in what order, so all you have to do is clearly communicate your already well developed argument. "Once I have the outline, my brain relaxes," explains Jeremy, a straight-A student from Dartmouth. "I don't need to think anymore about structuring the paper, but rather just think about how to best articulate my thoughts." Note, however, that this book is not about the mechanics of writing. This is a skill that you will need to develop on your own. In general, the more you write outside of class, the better; so, to improve your skills, try to write as much as you can. Also, don't be afraid to plunk a Chicago Manual of Style above your desk or flip through well-known style guides like William Zinsser's *On Writing Well*. These can help you focus and polish your writing, and professors appreciate clear exposition. This being said, there is not much left to cover. You know what you have to do: Put words on paper. It's not easy, but, if you followed the previous steps, it won't be nearly as agonizing as most students make it. I leave you with only three succinct pieces of logistical advice to help guide you through the process of combining your writing skills with your straight-A preparation to produce the best possible paper:

Separate Your Writing from the Steps That Come Before and After

As Greta, a straight-A student from Dartmouth, explains, when it comes to the writing process she "would map out a schedule, for example, write two pages a day for five days, and then edit one day." Ryan, another Dartmouth student, admits that he "usually gave about two days for the actual writing, but the research part of the paper usually happened a few weeks before." Both of these students' habits are instructed by a simple rule:

Separate your research from your writing and your writing from your editing.

Of course, this is not always practical for a small critical analysis essay, but it's crucial for a more substantial research paper. A fresh mind produces better results. It's hard to write well when you've spent an exhausting morning researching in the library. It's equally as hard to edit carefully when you have already spent hours that day writing the words you are about to review. "Having time away from the paper," explains Jeremy from Dartmouth, "allows you to come at it with better concentration."

Write in Quiet Isolation

Writing requires substantial concentration. If you work in an area with a lot of ambient noise, you will become distracted and your efficiency will decrease dramatically. Therefore, if you have a laptop, retreat to a distant, silent corner of a faraway building to work on your writing. “I am most productive,” explains Suzanne from Brown, “in a place where I have total silence and no external stimulation—for example, the library stacks.” As I emphasized in Part One of this book, avoid, if possible, study lounges, crowded areas of the library, and public computer labs. These places are noisy, and, as Rielle from Brown warns: “You’re always running into people and getting snagged by fascinating conversations.” If you don’t have a laptop, then work at the computer in your room at times when your roommates are in class or at meetings. If necessary, arrange in advance to kick them out for a few hours so you can work in peace. In addition, you should schedule your writing to correspond to your energetic high points during the day. For me, this meant working right after breakfast with my first cup of coffee. For others, this might be the early evening, right before dinner, or the afternoon after a post-lunch workout. The key is to recognize that writing is perhaps the most demanding (in terms of focus required) intellectual activity you will do while a college student. More so than reading, solving problem sets, or studying, writing demands all the energy and focus that you can manage.

Follow Your Outline and Move Slowly

Chris from Dartmouth offers simple advice for tackling the writing process: “I use the outline I’ve created as a guide and just sort of build from that, taking it one paragraph at a time.” Follow this example. Use your outline to direct your writing, setting up and expounding on each of the topics in a clear, cogent way, and copying and pasting quotes directly into your paper wherever needed. Keep your attention focused on the topic at hand. Your mind is free from concerns of structure and sources at this point, so you can concentrate on articulating specific points clearly and strongly. Always make sure your current point reads clearly before moving on to the next. Some students have success by writing their first draft quickly and sloppily, and then returning to clean it up in many successive editing rounds. In your case, however, because you’re working from a detailed topic outline, it will end up being quicker to write carefully the first time. Moving fast tends to produce time-consuming dead ends later on, and ultimately necessitates major rewrites. And, believe it or not, that’s all you need to know. So stop fearing writing! If you follow this system, this step, though still challenging, won’t take an excessive amount of time. Leave

the all-nighters to the average students, get your first draft done quickly and effectively, and then go have some fun.

Step 8 Fix, Don't Fixate

Editing your paper is important, and this shouldn't come as a surprise. If you hand in pages containing spelling and grammatical mistakes, the professor will be more than disappointed—she's likely to lower your grade as a result. Even if your argument is brilliant, it's really hard to get past those simple errors. This last step of the paperwriting process aims to free your work of these imperfections. At the same time, however, you don't want to overedit. Many students fixate on these fixes, and end up devoting hours to reviewing draft after draft. This act of academic self-flagellation is especially prevalent when working on big research papers. After all the work you dedicate to crafting a masterpiece of an argument, you begin to fear letting your baby out into the world. It's sort of like suffering from a nerdy version of Stockholm Syndrome— and it's a drag. “You can edit a paper forever and still not be satisfied,” explains Frank from Brown. “So it's important to know when to just print the damn thing out and send it off to its fate.” The goal here is to devise a simple system, something you can follow for every paper to help you root out the embarrassing typos and confusing constructions but also to prevent you from becoming a grammar psycho. Drawing from the advice given in my straight-A interviews, I present in this step a system that meets these criteria. It involves three simple passes through your draft. No more and no less. For those of you who are used to endless editing runs, the idea that three passes is enough might sound suspiciously quick. Or, if you're the kind of person whose idea of proofreading is hitting the spell-check button, multiple runs might seem hopelessly time consuming. But rest assured, the system is efficient and it gets the job done. As we will soon discuss, the key is the specific kind of attention given to each pass. Here is how it works:

The Argument Adjustment Pass

Your first pass through your work should be conducted on your computer. Read carefully, and focus on the on your computer. Read carefully, and focus on the presentation of your arguments—don't worry about small grammatical mistakes for the moment. Take in the paper one paragraph at a time. If a section is awkwardly stated, clarify the sentences. If it makes a point you already explained earlier, ruthlessly cut it out. If the argument is lacking detail, add in more sentences as necessary to fully explain your point. If a transition is lacking between topics or paragraphs, add one. Also be on the lookout for any major structural issues. Sometimes you don't realize until you finish an entire draft that your topic outline wasn't optimal. Don't be afraid to shift around major chunks of text. This is your

chance to make serious edits to the structure of your paper, so take this seriously. Do this editing at a time when you are rested and unhurried by upcoming appointments. For a large paper, spread this pass out over several days if possible. When you're done, your paper may still contain small mistakes. That's okay. You'll fix those next. The goal here is to tweak the argument until you're satisfied that it makes every point that you want to make in the order that you want to make them. Once you're done with this pass, these big picture details are locked in.

The Out Loud Pass

The Argument Adjustment pass is important, but not sufficient by itself. As Robert from Brown explains: "My papers always read differently on the page than on the screen." And as Melanie, a straight-A Dartmouth student, adds: "having a hard copy to read and mark up was absolutely necessary." Accordingly, for this next pass, you should first print out a copy of your paper, and then take it where you can have some privacy. With a pencil in hand, and this is the important part, begin to read your paper out loud. Don't cheat. Use a strong voice and articulate each word as if you're delivering a speech. For a long paper, it may take a long time to read the entire thing, so be prepared to split this into several sessions. You might also want water or hot tea on hand to prevent you from losing your voice. Whatever you do, however, don't avoid actually articulating every word. Whereas the last pass focused on your arguments, the goal of this pass is to root out small mistakes that might otherwise distract a reader from your engaging thesis. While reading, whenever you come across a grammatical mistake or an awkward construction, mark it clearly on the printout. Then go back up to the beginning of the preceding paragraph and start reading again. After you have marked up the entire document, go back to your computer and enter the changes you noted on your printout. A word of warning—this process always takes longer than expected, so leave yourself plenty of time. The rationale behind this approach is simple. As Ryan from Dartmouth explains: "Reading it out loud helps you catch typos or strange wording better than reading it in your head." No matter how many times you review a draft, if you're scanning silently, there are certain awkward phrases you might skip over every time—our subconscious minds have a habit of patching over these mistakes when reading our own writing. When you say the words out loud, on the other hand, your ear will catch even minor problems and draw your attention to them. "Something that looks fine on paper will jump out as strange or poorly worded when you hear it," explains Jeremy from Dartmouth. Therefore, by reading the paper out loud, you

will catch most mistakes in your paper in just one pass—requiring much less time than the multiple silent reviews necessary to achieve similar results.

The Sanity Pass

Because the previous passes were so careful, you're almost done, and you've only read through your work twice so far! Just to be sure that something embarrassing didn't slip through, it's a good idea to make a final, quick pass through a printed copy of your paper before handing it in. You don't have to do this pass out loud, and feel free to move through it quickly. But definitely use a printed copy, rather than reading on your computer screen, since a hard copy has a better chance of revealing a typo. If possible, separate this pass from the previous two. In fact, it's fine to do this the morning of the deadline. At this point, there should be no major mistakes lurking in your document. The goal here is twofold.

First, as mentioned, this last pass catches stray mistakes.

"I tried to always reread my papers before handing them in," explains James, a straight-A student from Dartmouth. "I try to smooth out any last kinks in the flow during that final editing."

Second, and perhaps more important, it also provides closure on your paper.

Because your work is so polished by this point, this final read-through should essentially go smoothly. As a result, you will develop a better feel for the flow and enjoy the experience of watching your argument unfold. This should help put your mind at ease. After all your work, think of this last pass as your reward. A final review before the paper leaves your hands, probably never to be read by you again. That's why we call it a sanity pass. Once you hand in your paper, you can now confidently tell yourself: "Unless I'm going insane here, I'm pretty sure that I just handed in a damn good piece of writing!"

Part Three Cheat Sheet

Step #1. Target a Titillating Topic

- Start looking for an interesting topic early.

Step #2. Conduct a Thesis-Hunting Expedition

- Start with general sources and then follow references to find the more targeted sources where good thesis ideas often hide.

Step #3. Seek a Second Opinion

- A thesis is not a thesis until a professor has approved it.

Step #4. Research like a Machine

- Find sources.
- Make personal copies of all sources.
- Annotate the material.
- Decide if you're done. (If the answer is "no," loop back to #1.)

Step #5. Craft a Powerful Story

- There is no shortcut to developing a well-balanced and easy-to-follow argument.
- Dedicate a good deal of thought over time to getting it right.
- Describe your argument in a topic-level outline.
- Type supporting quotes from sources directly into your outline.

Step #6. Consult Your Expert Panel

- Before starting to write, get some opinions on the organization of your argument and your support from classmates and friends who are familiar with the general area of study.
- The more important the paper, the more people who should review it.

Step #7. Write Without the Agony

- Follow your outline and articulate your points clearly.
- Write no more than three to five pages per weekday and five to eight pages per weekend day.

Step #8. Fix, Don't Fixate

- Solid editing requires only three careful passes:
 - The Argument Adjustment Pass: Read the paper carefully on your computer to make sure your argument is clear, fix obvious errors, and rewrite where the flow needs improvement.
 - The Out Loud Pass: Carefully read out loud a printed copy of your paper, marking any awkward passages or unclear explanations.
 - The Sanity Pass: A final pass over a printed version of the paper to check the overall flow and to root out any remaining errors.

Part 29: Parenting.

Step 195-What Should I Do As Parent

1. Train My Children on:

- Deep Work.
- UltraLearning.
- Classical Education.
- Christian Doctrine.
- Apologetics: why and what we believe.
- Philosophy.
- Logic, Arguments, EvidenceThinking.
- Reading.
- Talking, Communication.
- Always Raise Question. Never Let Anybody to Tells you cannot raise question and just Believe.
- Worldview and Science and Art.
- Understanding About The World.
- Language.
- Stoicism.
- History.
- How Propaganda Works.
- Reality of The World.
- Situational Awareness and Aware of Surroundings, Self Defence
- Not To be naive.
- Tactics
- Sport.

2. If the child asks why the moon is round. The Usual Adult answer is to discourage the child, what shape did you expect the moon to be? Instead of saying that, say to the child that this is interesting question, let's try to find out answer or maybe nobody knows the answer, and when you grow up you will be able to discover the answer, it would be very healthy for human species, if there were less discouragement and more scientists.
3. If the Kids wants a leverage to negotiate with me with anything they want. The Currency is Pages you read per day. It does not matter, if we are on vacation, it is Saturday or Sunday, the kids are always required to Read 20 Pages, every day.

That Starts at the age of Six. When the child turns six in the family, everyday reads 20 pages

- 4. Children are our first responsibility to teach them those things that They would not loose, when they go to School or University.**
- 5. I am as father need to provide leadership to my child at home.**
- 6. As Family Needs to involve in discipleship ministry.**
- 7. Introduce Alexandra and Adelina to Good Literature:**
 - Have A Deep Literature Hour with Both of them**
- 8. When Reading with Alexandra and Adelina, ask Question:**
 - What, who, when, where, why, How**
 - What does the text Says?**
 - What does the author mean based on text?**
 - Lets try to find what does the author mean by writing this**
 - Use Rules of Reading.**
- 9. Spend Time with Each Child One on one. One of the best Conversation are on one on one.**
- 10. Balance between competition and teamwork. Let the Kids have competition, but also let them learn to work as team.**
- 11. Teach Children to Debate with each other**
- 12. Teach The Children Independence.**
- 13. User Very rarely the Card *I Said So***
- 14. Choose The Right Movies with Lesson Behind.**
- 15. Create A Currency For Your Kids In The House. What is valuable for them to get in return from you, for what they want. The chores are what they supposed to do it. You do not get currency on Chores. The currency is like they need to read a book, exercise. Ask how many pages they finished, they answer is 20, perfect 20 points. If you want to watch TV you need to get 200 points, this means read 200 pages.**
- 16. Never compare Kids with other Kids. Compare the way they behave Yesterday and Today.**
- 17. Ask Your Kids for Their Opinion**
- 18. Discipline:**
 - Read 20 Pages a day every day and Discuss..**
 - Watch Documentaries and Discuss.**
 - If you want to have phone, you have to get straight A and B.**

- **Let the children play iPad, only Saturday and Sundays, but if the child misbehave then no Ipad, No Phone**

Step 196-You Have Required To Do The Work

1. When Give Opinion on Anything, Do Not Be so Angry and Mean to Others.
2. People Need To Stop Doing By Coming Unprepared To Give Opinion On Any Subject, Without Having Good Idea Of The Literature, and Arguments Written on Topic and Theme Available To Them. The people coming unprepared and not doing any Hard Work To Have an Opinion On The Subject or Topic. When People Coming Overconfidence, which could be resulting in Lack of Preparation, Which Could Lead That Your Position can be Destroyed with Ease. They simply won't do the work required. It's easy to come home, sit on the couch, watch TV, and zone out until bedtime rolls around. But that's not going to help you get smarter.
 - A. People Who Do Not Put The Required Work: The first thing they always do is tell you what they think. When someone has an opinion about everything, they want to share it with you. They often tout stats and research as if they had an imaginary checklist of facts they need to be able to rattle off to establish themselves as an expert in a field they actually know very little about. Because they have an opinion on everything, they are quick to judge others – for their lack of opinions, for their lack of knowledge, for their lack of outrage, and the list goes on.
 - B. People who have opinions about everything barf so much noise that it's hard to find the signal. Your brain has to work overtime to figure out if they did the work to come up with their opinions themselves or if they're simply regurgitating some oped in a newspaper. Over time, opinionated people also end up in their own prisons and they try to take you with them.
 - C. The problem comes from how we see the world. Our opinions are often rooted in how we think the world should work, according to our morals, values, and principles. If we see the world through the lens of our opinions, much of what happens will not agree with us. This is feedback, and how we respond to this feedback is key.

3. How to Get Smarter Read. A lot. Warren Buffett says, "I just sit in my office and read all day." What does that mean? He estimates that he spends 80% of his working day reading and thinking. When asked how to get smarter, Buffett once held up stacks of paper and said, "Read 500 pages like this every week. That's how knowledge builds up, like compound interest." All of us can build our knowledge, but most of us won't put in the effort. "Go to bed smarter than when you woke up."
4. How Long Does it Take To Prepare:
 - A. Depend on the topic and opponent, and how much he's written.
 - B. If the opponent nothing published, then there was very little preparation to be made because I simply didn't know what to expect.
 - C. On the other hand, if the opponent has published lots of written work and have some videos. Read and what his written and videos and prepare the summaries articles, videos, and have sense where he is coming from. This can take Weeks or Months.
5. Be informed citizen is read more classical books and history. This unfolds how the real world works and where it is going. If You read Classical Books, then you can well predict what would happen next in the future based on the events happening.
6. Do not read the newest books, but the great books of western world, stoic and classics, as these books stood the test of time.
7. Do Not Have the Opinion and do not make any judgement about Anything, I see and hear, If I did not work Hard to have an opinion. I need to Read, Analyse, Research the topic from every angle, so that I can have an opinion or Make Judgement on the topic.

8. Before Preparation. The difference between the people who do the work and the people who just reel off memorized opinions is huge. When you do the work, you can answer the next question. You know when to follow the rules and when they'll get you in trouble. When I did my postgraduate I was surrounded by people who could answer the test questions. They got good grades — actually, they got *great* grades but an odd thing happened after school: a lot of those people couldn't apply their knowledge to problems they hadn't seen before. They were chauffeurs — they knew the memorized answer. They couldn't answer the next question. We're all chauffeurs in some aspects of our lives. This is why understanding your circle of competence is so critical to living a rational life.

I. Circle of Competence:

A. **Circle Of Competence**-Understanding my Circle of Competence helps to avoid problems, identify opportunities for improvement and learn from Others. Circle of Competence is simple: Each of us, through experience or study, has built up useful knowledge on certain areas of the world. Some areas are understood by most of us, while some areas require a lot more specialty to evaluate. For example, most of us have a basic understanding of the economics of a restaurant: You rent or buy space, spend money to outfit the place and then hire employees to seat, serve, cook, and clean. (And, if you don't want to do it yourself, manage.) From there, it's a matter of generating enough traffic and setting the appropriate prices to generate a profit on the food and drinks you serve—after all of your operating expenses have been paid. Though the cuisine, atmosphere, and price points will vary by restaurant, they all have to follow the same economic formula. That basic knowledge, along with some understanding of accounting and a little bit of study, would enable one to evaluate and invest in any number of restaurants and restaurant chains, public or private. It's not all that complicated. Far more important is to honestly define what we do know and stick to those areas. Our circle of competence can be widened, but only slowly and over time. Mistakes are most often made when straying from this discipline. Where should we devote our limited time in life, to achieve the most success? So, the simple takeaway here is clear. If you want to improve your odds of success in life and business, then define the perimeter of your circle of competence, and operate inside. Over time, work to expand that circle

but never fool yourself about where it stands today, and never be afraid to say “I don’t know.”

II. Two Type of Knowledge: The Max Planck and Chauffeur Test

A. The Two Types of Knowledge: The Max Planck and Chauffeur Test: How to distinguish between the two types of knowledge: real knowledge and pretend knowledge.

- The first type of knowledge is real. It can’t be bought. It can’t be copied. If you want real knowledge you need to earn it. One is Planck knowledge, the people who really know. They’ve paid the dues, they have the aptitude. You are going to have the problem in your life of getting the responsibility into the people with the Planck knowledge and away from the people with the chauffeur knowledge. Real knowledge comes when people do the work. The problem is that it’s difficult to separate the two. This is the Batesian Mimicry problem. One way to tease out the difference between Planck and chauffeur knowledge is to ask them why.
- The second type of knowledge is copied. On the surface you know the answer but you lack the understanding to show your work. Then we’ve got chauffeur knowledge. They’ve learned the talk. They may have a big head of hair, they may have fine temper in the voice, they’ll make a hell of an impression. But in the end, all they have is chauffeur knowledge. I think I’ve just described practically every politician in the United States. We have the people who don’t do the work — they pretend. While they’ve learned to put on a good show, they lack understanding. They can’t answer questions that don’t rely on memorization. They can’t explain things without using jargon or vague terms. They have no idea how things interact. They can’t predict the consequences. The problem is that it’s difficult to separate the two. This is the Batesian Mimicry problem. One way to tease out the difference between Planck and chauffeur knowledge is to ask them why.
- How To Distinguish Real Knowledge and Fake Knowledge. With journalists, it is more difficult. Some have acquired true knowledge.

Often they are veteran reporters who have specialized for years in a clearly defined area. They make a serious effort to understand the complexity of a subject and to communicate it. They tend to write long articles that highlight a variety of cases and exceptions. The majority of journalists, however, fall into the category of chauffeur. They conjure up articles off the tops of their heads or, rather, from Google searches. Their texts are one-sided, short, and— often as compensation for their patchy knowledge. The same superficiality is present in business. The larger a company, the more the CEO is expected to possess “star quality.” Dedication, solemnity, and reliability are undervalued, at least at the top. Too often shareholders and business journalists seem to believe that showmanship will deliver better results, which is obviously not the case. One way to guard against this is to understand your circle of competence. Dobelli concludes with some advice worth taking to heart. Be on the lookout for chauffeur knowledge. Do not confuse the company spokesperson, the ringmaster, the newscaster, the schmoozer, the verbiage vendor, or the cliché generator with those who possess true knowledge. How do you recognize the difference? There is a clear indicator: True experts recognize the limits of what they know and what they do not know. If they find themselves outside their circle of competence, they keep quiet or simply say, “I don’t know.” This they utter unapologetically, even with a certain pride. From chauffeurs, we hear every line except this.

III. Batesian Mimicry Problem. Batesian Mimicry: Why Copycats Are Successful.

Mimic and the Real Thing:

- A. "There's two kinds of snakes you come across. There's the Texas Coral Snake, and the Mexican Milk Snake, and they both look exactly alike. The Texas Coral Snake is dangerous, it's venomous, it can kill you in a minute. The Mexican Milk Snake can't do anything to you; it's an impostor." How is it that these two look alike? It's due to a phenomenon called Batesian Mimicry.
- B. In the 1850s, the naturalist Henry Walter Bates found a certain set of butterflies who were clearly *not* of the same species but whose wings looked almost the same to the naked eye. After thinking it over, Bates eventually figured out what was going on: While the butterflies which were toxic to potential predators (the "models") were able to operate freely and relatively unmolested, there had also developed a "mimic" population of butterflies which wasn't toxic at all, yet still went untouched! In fact, biologists eventually figured out that the more toxic and dangerous the "model" was and the more frequently they appeared in the local population, the easier it was for its "mimics" to get by! Predators simply wouldn't take the risk of mixing up the two. If there aren't as many "models" around or they aren't that dangerous, the mimics have a harder time.
- C. This is a wonderful model, and in the practical world we live in, a similar phenomenon abounds: Copycats or "pretenders to the throne" are often very effective, very convincing "mimics" of the true champions. They dress the part, they talk the talk, and they know what buttons to push. But in the end, they are merely chauffeurs. We see a very Batesian effect at work: The more impressive the "model," the more effective its mimics can be in convincing people they too are impressive, and in all the same ways. But for every Warren Buffett (just one by our count), there has been many "future" Warren Buffett's. For every Steve Jobs, there have been many "next" Steve Jobs'. In fact, sometimes even just *appearances* can be quite convincing: now-disgraced Theranos founder Elizabeth Holmes was very fond of wearing a very Steve Jobsian black turtleneck outfit. Because they can be very convincing, we must be wise enough to watch out for Batesian mimicry

— even in ourselves. This brings up an interesting, at times paradoxical, question: Who can best tell the difference between a Coral Snake and its Mimics? The Coral Snake itself. The real thing knows a fake. It's worth taking the time to work on learning all the big ideas you can find, not just the ones you want to learn. In that search, you'll find a host of big winners you didn't even know existed.

9. Preparation:

- A. While we all hold an opinion on almost everything. Have I do the work required to have an opinion on any Subject? Never allow myself to have an opinion on anything that I don't know the other side's argument better than they do. The work required to have an opinion is very hard part, have I avoid it?
 - I. I have to do the reading.
 - II. I have to talk to competent people and understand their arguments.
 - III. Never try to be biased toward any of the side, but question both side of the argument.
 - IV. Do not support any side, until all the facts are put out there, clear and obvious.
 - V. Once known all the facts then analyse both sides of the argument like William Lane Craig.
 - VI. I have to think about the key variables and how they interact over time.
 - VII. I have to listen and chase down arguments that run counter to your views.
 - VIII. I have to think about how you might be fooling yourself.
 - IX. I have to see the issue from multiple perspectives.
 - X. I have to think.
 - XI. I need to become your most intelligent critic and have the intellectual honesty to kill some of your best-loved ideas.
 - XII. Be honest with yourself and open minded. ANALYSE both side of the argument logically and see which is true logically. Means has the clear terms, premises are true, and conclusion follows from premises.
 - XIII. Never say your opinion about anything that requires the analysis of the arguments and facts. Work very bery hard to have an opinion about anything.
 - XIV. Listen very carefully other side and use ancient method *state the opposition argument in my own words and ask him/her if the argument I

stated in my own words represents correctly their argument and if I UNDERSTOOD Correctly their arguments.

XV. Never use cheap shots to win argument, like logical fallacies.

XVI. Debate and discussion is not about just win at any cost, but let other person to think about your arguments and engage with them. Second reason never use in discussion cheap shots toward other person, but be civil. Third reason is win the debate and discussion. Fourth is find the truth.

B. For Affirmative and Negative Case:

- I. Read, analyse, Research, Syntopicon and Investigate Published Work.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of My own Arguments
- II. Read Opponents Books, Articles, Newspapers, Blogs. Reading Published work. What objections he would raise against the topic and prepare the responses for each of these points.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of opponent Arguments.
- III. Watch Video. Watching Videos of the opponent. What objections he would raise against the topic and prepare the responses for each of these points.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of My own Arguments.
- IV. Listen The recording that the opposition made, in which he addresses these issues.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of My own Arguments.
- V. Talk with People who are students in his class, who can tell me, privately, insights into his thinking and character.
- VI. If that sounds like a lot of work, just say, “I don’t have an opinion on that; why don’t you tell me how you got to have such a firm one? It sounds like I could learn something.”
- VII. Another way to get smarter, outside of reading, is to surround yourself with people who are not afraid to challenge your ideas. “Develop into a lifelong self-learner through voracious reading; cultivate curiosity and strive to become a little wiser every day.”

10. Compound Knowledge- Are The Resources I will Choose Concentrating On the Expiring Information or Compound Knowledge?

- I. Are on the Resources providing expiring information?
 - A. Will you care about what you're reading in a month? In a year? In five years?
 - B. Are you focused enough on the same thing to build cumulative knowledge or are you too spread out?
 - C. What do you spend time on that's likely to change in the next few years? What's not likely to change?
 - D. What would need to happen for you to stop outsourcing organisation of information to the computer?
- II. Signs of The Information in the resources are expiring
 - A. First, it's marketed to you.
 - B. Second, lacking details and nuance, it's easily digestible. This is why it's commonly telling you what happened, not why it happened or under what conditions it might happen again
 - C. Third, it won't be relevant in a month or a year. Expiring information is one reason I stopped reading most news. It's a false map.
- III. While most of us focus on consuming information that we won't care about next month, let alone next year, focus on knowledge and companies that change very, very slowly or not at all. And because the information he was learning changed slowly he could compound his knowledge over time.
- IV. Doing his own thinking and vacuums up the details. When we don't think for ourselves it's easy to put the blame on someone else, to "pass the buck" so to speak.
- V. When we consume information that doesn't expire or expires slowly; is very detailed; and we spend time thinking about it not passing the buck, we can match patterns. This is how you learn to see what other people are missing. The longer you do this, the more advantage you get.
- VI. Just like the rest of us, Buffett's dependent on information and knowledge to make great decisions. Unlike most of us, he has a great memory—perhaps because he's not trying to outsource his memory or thinking to others.
- VII. A lot of what the snowball is about the concept of learning, and creating, and the advantage of having the information and knowing it. When I came here today one

of the things that I was thinking is that what you do is so much at the intersection, because retrieving information is different from having it already in your head.

VIII. What you do is different. You work on manipulating how you use the information.

In fact, Warren Buffett and Charlie Munger have the files in their head. That's why they aren't really out there googling all the time looking for, trying to look stuff up, because they already know it.

IX. I think a lot of the work that you do here is helpful to the ordinary person, but Warren Buffett or Charlie Munger don't need it. At the same time, the lesson that they have, which is that learning yourself, making yourself as smart as you can is extremely valid, and not just relying on a library where you can look something up all the time, because a lot of times when you need to make a decision, and you need 50 pieces of information, you need to know it then.

11. The Art of Anticipation of Objections.

- A. Analyse My Arguments, and Scrutinise The arguments by using Rules of Reading.
- B. Analyse the arguments of the opponent. Scrutinise Their arguments by using Rules of Reading.
- C. Analyse My own arguments. Scrutinise My own arguments, and the potential Loopholes in the argument by Use Rules of Reading.
- D. Use Think, Logic, Strategem, Thinking models.
- E. Write.
- F. Prepare The responses to anticipated objections that, I think the opponent will bring up.
- G. Be intellectually Prepared. This means That I need to know my arguments, so well, that nothing new can surprise me. I would also invest lots of time in knowing and know better opposite side arguments. I would read both side of the arguments, and work Hard on analysing the arguments and evidence of both sides. Doing the work required to hold an opinion means you can argue against yourself better than others can. Only then can you say, "I can hold this view because I can't find anyone else who can argue better against my view." Great thinkers, like Charles Darwin, did the work. And it's one of the biggest reasons he's buried at Westminster Abbey. While we all hold an opinion on almost everything. Have I do the work required to have an opinion on any Subject? Never allow myself to have an opinion on anything that I don't know the other side's argument better than they do. The work required to have an opinion is very hard part, have I avoid it? If that sounds like a lot of work, just say, "I don't have an opinion on that; why don't you tell me how you got to have such a firm one? It sounds like I could learn something."
- H. Doing the work required to hold an opinion means you can argue against yourself better than others can. Only then can you say, "I can hold this view because I can't find anyone else who can argue better against my view." Great thinkers, like Charles Darwin, did the work. And it's one of the biggest reasons he's buried at Westminster Abbey.
- I. Doing the work counteracts our natural desire to seek out only information that confirms what we believe we know. When Darwin encountered opinions or facts that ran contrary to his ideas, he endeavored not only to listen but also not to rest

until he could either argue better than his challengers or understand how the fact fit. Darwin did the work. It's wasn't easy, but that's the point.

- J. Have the best work ethic on daily basis. This is everyday process, and try to figure it out, the strengths and weaknesses of my position and opposing person position, This leads to the True Confidence.
- K. As Per Kobe Bryant statement: Trivial things should not be taken your attention. The attentions should be focused on things that is very important. Anything outside of the most important things in life, you should not have time for. You Should love the challenge in life, and always be curious, if you can be at the top , as these greats in that area. Always focus on one thing and not multiple things, this gives an edge and advantage over other people, who focusing on multiple things in life. The World Becomes a library to you, to be better at your craft.: Everything you see whether TV show I saw, Books, Journals, I read, whether discussion, debate I listen, people I talk to. Everything was done to try to learn to become better at the craft your focusing. When you have this point of view, then the world becomes your library to help you to become better at the craft.
- L. I Always need to ask myself: Have I done the work required to have an opinion on any Subject? Never allow myself to have an opinion on anything that I don't know the other side's argument better than they do. The work required to have an opinion is very hard part, have I avoid it? If that sounds like a lot of work, just say, "I don't have an opinion on that; why don't you tell me how you got to have such a firm one? It sounds like I could learn something."
- M. I might need to Suspend my judgement and tell them that I do not have an opinion on this specific Topic.
- N. Never Under Prepare, but Vastly Over Prepare for the Opponent and their arguments and responses
- O. Spend years in preparation, take debate class at the college or university. You need to participate in debates. You need to have mock debates, where someone play role of your opponent, and then you respond to them. You need to do reading and learn how to flow the debates. How to construct affirmative case and negative case. You need to take time to prepare and have enormous preparation.
- P. Memorize the arguments for my case

12. When Dialogue, Discussion, Debate Takes A Place.

A. As Affirmative Speaker, you need to present Prima Facie Case for proposition that is under debate. Prima Facie Case will be one that will establish the truth of proposition you are defending. If I am defending proposition that God Exist, I will want to give 3-5 arguments leading to that Conclusion, that God Exists, and then I will lay those out with great clarity in my opening speech, and say this is the groundwork for the debate. I am not interested in talking about other issues for example if Christianity bad for society Then, I come back to those in every speech over and over again. The goal is to make opponent argue on your grounds. You do not go over to his grounds, and let your audience forget, your affirmative case, rather you reorganise opponent speech, so that you answer his objections in so far as they reply to your arguments, so you may answer them in a very different order than he gave them, because you will be seeing for example: now what answer or response did he have to the cosmological argument, I see two basic responses and then you deal with them.

- Make Briefs, where I have suitable objection, and then have two or three responses to those objections.
- Use The Brief During Exchange with the Opponent. File these Briefs into Folders, and spread These Manila Folders out in front of me on Desk, When I am interacting with the Opponent. Once the opponent Rises his point I just pull These briefs from these folders and never have to think on my feet because I am completely prepared. Key is never have to think on the feet to be so well prepared, that I would have my responses ready for anything he brings up.
- Quote Peer Review Scientific Articles on the topic in support the conclusions.

B. Take Notes While the Opposition is speaking:

- How To Take Notes- Flow Chart. By Taking Notes, I am sure that I am responding to my opponent's arguments and everything he brings up.

- I. Make 11-12 Columns on the Pad. Prepare the left column in advance of the communication, debate. The Left Column needs to be filled in, if you starting first. If not, then leave left column as blank.
- II. First Left Hand Column Are My Arguments.
- III. Second Left Hand Column are Opposition Arguments and Responses to My arguments.
- IV. Third Left Column are My Responses to the Opponent responses.
- V. Fourth Left Hand Column are My Rebuttal.
- VI. Fifth Left Hand Column are Opponent Rebuttal.
- VII. Sixth Left Hand Column are my Responses to the Opponent rebuttal.
- VIII. Seventh Left Hand Column is the Final My Rebuttal.
- IX. Eight Left Hand Column is The opponent Rebuttal.
- X. Ninth Left Hand Column is my closing statements.
- XI. Tenth Left Hand Column is the opponent closing statements.
- XII. Eleventh Left Hand Column is the Cross Examination.
 - My Answer.
 - Opponent Answer.
 - My response to the response of the opponent.

- C. Always Remind the audience what are your three to five arguments and what are the responses of the opponent, if any to your arguments.
- D. Always allow the opponent allow to lay out his argument without interruption.
- E. Take the opponent arguments and put in my own words and correctly represent their argument carefully without misrepresentation.
- F. Be Honest.
- G. Be Open Minded.
- H. Always from Your side be honest and rigorous exchange of arguments and counter Arguments from which me and opponent would benefit.
- I. One of good technique is whenever you can quote an opponent against himself, this is powerful device. Have the manuscript, point to the footnote, cite the book, and the quotation and have the page number.
- J. Never Take Cheap Shots at the Opponent.

- K. Encourage not just trust someone say so, but demand published peer reviewed articles in support of the positions that one take
- L. Always look at the reality of the situation, and do not let the emotion cloud the situation and the execution. Always be in the present and the moment.

Step 197-Letting The World Do The Work For You

1. Listen and Apply book
 - I. This Explains Everything_ Deep, Beautiful, and Elegant Theories of How the World Works
2. **The world never tells you that you're wrong; it only gives you outcomes.**
3. **Don't force. Don't resist. Have a beginner's mind. Let the world teach you.**
4. **Reality will do a lot of the work for us if we simply align with it. Most of the time we're simply adding friction because we want the world to work in the way we think it should.**
5. **If you don't see the world the way it is, you'll think it works in a way that it doesn't and make terrible mistakes. The key to getting what you want out of life is to identify how the world works and align yourself accordingly. This is hard because we think the world should work the way we see it. The word "should" is important. Because we think the world should work in a way that it doesn't, our approach is suboptimal. What the pupil must learn, if he learns anything at all, is that the world will do most of the work for you, provided you cooperate with it by identifying how it really works and aligning with those realities. If we do not let the world teach us, it teaches us a lesson. Joseph Tussman**
6. When an outcome is not what you want it to be, things get tough. You can ignore the result and continue to think that you're right. This protects your ego. It also carries the risk of your continuing to believe something that isn't true. Alternatively, you can calibrate your believability on the subject at hand by lowering the odds that you're right. For example, maybe you gave yourself an 85 out of 100 for the ability to hold a firm opinion on this subject, and now you lower your score to 75. If the world continues to provide undesirable outcomes, eventually you get the hint and change your beliefs. Finally, you can give up your opinions and just respond to the world as it is. This option is the hardest.
7. You do not create the way the world works, you can only align yourself with it. It takes a lot of work to align ourselves with reality. When we don't get the outcome we're seeking, the last place we look is inside ourselves. Instead, we blame others or

circumstances. If you want to align yourself with reality, you have to work at it and care about it. There are two keys to aligning yourself with how the world really works: accepting feedback and stopping bargaining.

- I. We let people, not results, guide our behavior. The world tries to tell us when we don't see it the way it is. The problem is we don't listen to the world. Instead, we let others tell us what's right and wrong, what works, and what doesn't. Common actions get common results. Most of our actions come from others. We want what they want. Even worse, we employ the same actions to get it. This isn't always wrong. If you're just starting, the quickest path to average is to copy. If you want better results than average, you're going to have to iterate. Doing something different means we might look like a fool, and we do not want to look like a fool. Iterating means trying something new, it means you might fail. Show me a person who's afraid to look bad, and I'll show you a person you can beat every time. If we do what everyone else is doing, we're going to get the same results that everyone else is getting. Different results demand different actions. If you can't really fail, you can't really succeed. Let results, not popularity, determine your actions. If you're doing something that doesn't get you the results you want, try something new. If you're doing something that seems to work, keep doing it. Consistently repeat successful actions.
- II. Bargaining with the world doesn't work. A lot of otherwise smart people know what they're doing isn't getting the results they want, but because they think the world *should* work in a way that it doesn't, they keep repeating them hoping for different results. If you are this person, see it for what it is, and change your actions. The feedback from the world is often painful. Often, it is this very pain that causes us to no longer delude ourselves with how the world should work and accept how it does work. If you can learn to accept the world for how it is, before suffering, you'll go faster and further. Outcome over ego. If you think you know how the world works but you're doing something that gets suboptimal results because it *should* work a different way, you don't really know how the world works. Rational people take feedback from the world. If you want to know how someone sees the world, look at their actions. In the end, it's all your fault. You are accountable for your outcomes. When you take responsibility for your outcomes, you naturally accept feedback from reality. When you get feedback from reality, you adjust your behavior.

- III. As Per Kobe Bryant statement: Trivial things should not be taken your attention. The attentions should be focused on things that is very important. Anything outside of the most important things in life, you should not have time for. You Should love the challenge in life, and always be curious, if you can be at the top , as these greats in that area. Always focus on one thing and not multiple things, this gives an edge and advantage over other people, who focusing on multiple things in life. The World Becomes a library to you, to be better at your craft.: Everything you see whether TV show I saw, Books, Journals, I read, whether discussion, debate I listen, people I talk to. Everything was done to try to learn to become better at the craft your focusing. When you have this point of you, then the world becomes your library to help you to become better at the craft.
- IV. Have the best work ethic on daily basis. This is everyday process, and try to figure it out, the strengths and weaknesses of my position and opposing person position.
- V. Always look at the reality of the situation, and do not let the emotion cloud the situation and the execution. Always be in the present and the moment.
- VI. If you understand the world as it really is, not as you'd wish it to be, you will begin to make better decisions almost immediately. Once you start making better decisions the results compound. Better initial decisions free up your time, reduce your stress, allowing you to spend more time with your family and leave your competition in the dust.
- VII. How can we best understand the world as it is? Acquiring knowledge can be a very daunting task. If you think of the mind as a toolbox, we're only as good as the tools at our disposal. A carpenter doesn't show up to work with an empty toolbox. Not only do they want as many tools in their toolbox as possible, but they want to know how to use them. Having more tools and the knowledge of how to use them means they can tackle more problems. Try as we might, we cannot build a house with only a hammer. If you're a knowledge worker, you're a carpenter. But your tools aren't bought at a store and they don't come in a red box that you carry around. Mental tools are the big ideas from multiple disciplines, and we store them in our mind. And if we have a lot of tools and the knowledge required to wield them properly, we can start to synthesize how the world works and make better decisions when confronted with problems.
- VIII. This is how we understand and deal with reality. The tools you put into your toolbox are Mental Models. Mental models are a framework for understanding

how the world really works. They help you grasp new ideas quickly, identify patterns before anyone else and shift your perspective with ease. Mental Models allow us to make better decisions, scramble out of bad situations, and think critically. If you want to understand reality you must look at a problem in multiple dimensions — how could it be otherwise? Getting to this level of understanding requires having a lot of tools and knowing how to use them. You knew there was a hitch right? We need to change our fast-food diet of information consumption and adopt the healthier diet of knowledge that changes slowly over time. While changing diets isn't easy, it can be incredibly rewarding: more time, less stress, and being better at your job. The costs, however, are short term pain for long-term gain. You must change how you think.

- IX. 2nd Order Thinking. One example of a model we can immediately conceptualize and use to improve our ability to make better decisions is something we can borrow from ecology called second-order thinking. The simple way to conceptualize this is to ask yourself "If I do X, what will happen *after* that?". I sum this up using the ecologist Garrett Hardin's simple question: "And then what?" A lot of people forget about higher order effects — second and third-order effects or higher. I've been in a lot of meetings where decisions are made and very few people think to the second level, let alone the third. Rather, what typically happens is called first conclusion bias. The brain shuts down and stops thinking at the first idea that comes to mind that seems to address the problem as you understand it. We don't often realize that our first thoughts are usually not even our own thoughts. They usually belong to someone else. We understand the sound-byte but we haven't done the hard work of real thinking. After we reach the first conclusion, our minds often shut down. We don't seek evidence that would contradict our conclusion. We don't ask ourselves what the likely result of this solution would be — we don't ask ourselves "And then what?" We don't ask what other solutions might be even *more* optimal. For example, consider a hypothetical organization that decides to change their incentive systems. They come up with a costly new system that requires substantial changes to the current system. Only they don't consider (or even understand) the problems that the *new* system is likely to create. It's possible they've created more problems than they've solved — only now there are *different* problems they must put their head down to solve. Optically, they "reorganize their incentive programs," but practically, they've simply expended energy to stay in place. Another, perhaps more complicated,

example is when a salesman comes into a company and offers you a software program he claims will lower your operating costs and increase your profits. He's got all these beautiful charts on how much more competitive you'll be and how it will improve everything. This is exactly what you need because your compensation is based on increasing profits. You're sold. Then second-order thinking kicks in and you dare to ask how much of those cost savings are going to go to you and how much will eventually end up benefits enjoyed by customers? To a large extent, that depends on the business you're in. However, you can be damn sure the salesman is now knocking on your competitor's door and telling them you just bought their product and if they want to remain competitive they better purchase it too. Eventually, you all have the new software and no one is truly better off. Thus, in the manner of a crowd of people standing on their tip-toes at a parade, all competitors spend the money but none of them win: The salesman wins and the customer wins. We know, thanks to people like Garrett Hardin, Howard Marks, Charlie Munger, Peter Kaufman, and disciplines like ecology, that there are second and third-order effects. This is how the world really works. It just isn't always a comfortable reality. Understanding how the world works isn't easy and it shouldn't be. It's hard work. If it were easy, everyone would do it. And it's not for everyone. Sometimes, if your goal is to maximize utility, you should focus on getting very, very good in a narrow area and becoming an expert, accepting that you will make many mistakes outside of that domain. But for most, it's extremely helpful to understand the forces at play outside of their narrow area of expertise. Because when you think about it, how could reality be anything other than a synthesis of multiple factors? How could it possibly be otherwise?

- X. When our mental models line up with reality, they help us avoid problems. However, they also cause problems when they don't line up with reality as we think something that isn't true.
- XI. We must be open to other perspectives if we truly want to understand the results of our actions. Despite feeling that we've got all the information, if we're on the ship, the fish in the ocean has more he can share. The second flaw is ego. Many of us tend to have too much invested in our opinions of ourselves to see the world's feedback—the feedback we need to update our beliefs about reality. This creates a profound ignorance that keeps us banging our head against the wall over and over again. Our inability to learn from the world because of our ego happens for many reasons, but two are worth mentioning here. First, we're so

afraid about what others will say about us that we fail to put our ideas out there and subject them to criticism. This way we can always be right. Second, if we do put our ideas out there and they are criticized, our ego steps in to protect us. We become invested in defending instead of upgrading our ideas. The third flaw is distance. The further we are from the results of our decisions, the easier it is to keep our current views rather than update them. When you put your hand on a hot stove, you quickly learn the natural consequence. You pay the price for your mistakes. Since you are a pain avoiding creature, you update your view. Before you touch another stove, you check to see if it's hot. But you don't just learn a micro lesson that applies in one situation. Instead, you draw a general abstraction, one that tells you to check before touching anything that could potentially be hot. Organizations over a certain size often remove us from the direct consequences of our decisions. When we make decisions that other people carry out, we are one or more levels removed and may not immediately be able to update our understanding.

Part 30: Sales.

Step 198-Books On Sales

1. **Listen, Follow And Apply Rules of Reading Part 1 to 22, before looking into Sales.**
2. **Listen, Follow and Apply the following Books.**
 - A. Socratic Selling.
 - B. 13 Things Mentally Strong People Don't Do.
 - C. The 80/20 Principle By Richard Koch.
 - D. Eat That Frog By Brian Tracy.
 - E. How To Speak How To Listen by Mortimer Adler.
 - F. How To Sell When Nobody's Buying by Dave Lakhani.
 - G. How To Sell Yourself by Arch Lustberg,
 - H. How to Talk TO Anyone.
 - I. 80/20 Sales and Marketing by Perry Marshall.
 - J. Pareto's 80/20 Rule for Corporate Accountant.
 - K. The Ultimate Sales Machine By Chet Holmes.
 - L. Seven Habits of Highly Effective People.
 - M. 80/20 Investor,
 - N. The 80/20 Principle
 - O. Challenger Sale
 - P. SaLES bIBLE
 - Q. Art of Closing Sale
 - R. PSYCHOLOGY OF SALES
 - S. uNLIMITED sales Success.
3. Take 4 subjects: a. Sales, b. Negotiations c. Human Nature d. Money. Take a list from Amazon with 4stars and above and read every books on those topics. For 2 years obsess over doing that and you will go farther in the market place. Market reward the people who outworks and improve.

Step 199-You Have Required To Do The Work

1. When Give Opinion on Anything, Do Not Be so Angry and Mean to Others.
2. People Need To Stop Doing By Coming Unprepared To Give Opinion On Any Subject, Without Having Good Idea Of The Literature, and Arguments Written on Topic and Theme Available To Them. The people coming unprepared and not doing any Hard Work To Have an Opinion On The Subject or Topic. When People Coming Overconfidence, which could be resulting in Lack of Preparation, Which Could Lead That Your Position can be Destroyed with Ease. They simply won't do the work required. It's easy to come home, sit on the couch, watch TV, and zone out until bedtime rolls around. But that's not going to help you get smarter.
 - A. People Who Do Not Put The Required Work: The first thing they always do is tell you what they think. When someone has an opinion about everything, they want to share it with you. They often tout stats and research as if they had an imaginary checklist of facts they need to be able to rattle off to establish themselves as an expert in a field they actually know very little about. Because they have an opinion on everything, they are quick to judge others – for their lack of opinions, for their lack of knowledge, for their lack of outrage, and the list goes on.
 - B. People who have opinions about everything barf so much noise that it's hard to find the signal. Your brain has to work overtime to figure out if they did the work to come up with their opinions themselves or if they're simply regurgitating some oped in a newspaper. Over time, opinionated people also end up in their own prisons and they try to take you with them.
 - C. The problem comes from how we see the world. Our opinions are often rooted in how we think the world should work, according to our morals, values, and principles. If we see the world through the lens of our opinions, much of what happens will not agree with us. This is feedback, and how we respond to this feedback is key.

3. How to Get Smarter Read. A lot. Warren Buffett says, "I just sit in my office and read all day." What does that mean? He estimates that he spends 80% of his working day reading and thinking. When asked how to get smarter, Buffett once held up stacks of paper and said, "Read 500 pages like this every week. That's how knowledge builds up, like compound interest." All of us can build our knowledge, but most of us won't put in the effort. "Go to bed smarter than when you woke up."
4. How Long Does it Take To Prepare:
 - A. Depend on the topic and opponent, and how much he's written.
 - B. If the opponent nothing published, then there was very little preparation to be made because I simply didn't know what to expect.
 - C. On the other hand, if the opponent has published lots of written work and have some videos. Read and what his written and videos and prepare the summaries articles, videos, and have sense where he is coming from. This can take Weeks or Months.
5. Be informed citizen is read more classical books and history. This unfolds how the real world works and where it is going. If You read Classical Books, then you can well predict what would happen next in the future based on the events happening.
6. Do not read the newest books, but the great books of western world, stoic and classics, as these books stood the test of time.
7. Do Not Have the Opinion and do not make any judgement about Anything, I see and hear, If I did not work Hard to have an opinion. I need to Read, Analyse, Research the topic from every angle, so that I can have an opinion or Make Judgement on the topic.

8. Before Preparation. The difference between the people who do the work and the people who just reel off memorized opinions is huge. When you do the work, you can answer the next question. You know when to follow the rules and when they'll get you in trouble. When I did my postgraduate I was surrounded by people who could answer the test questions. They got good grades — actually, they got *great* grades but an odd thing happened after school: a lot of those people couldn't apply their knowledge to problems they hadn't seen before. They were chauffeurs — they knew the memorized answer. They couldn't answer the next question. We're all chauffeurs in some aspects of our lives. This is why understanding your circle of competence is so critical to living a rational life.

I. Circle of Competence:

A. **Circle Of Competence**-Understanding my Circle of Competence helps to avoid problems, identify opportunities for improvement and learn from Others. Circle of Competence is simple: Each of us, through experience or study, has built up useful knowledge on certain areas of the world. Some areas are understood by most of us, while some areas require a lot more specialty to evaluate. For example, most of us have a basic understanding of the economics of a restaurant: You rent or buy space, spend money to outfit the place and then hire employees to seat, serve, cook, and clean. (And, if you don't want to do it yourself, manage.) From there, it's a matter of generating enough traffic and setting the appropriate prices to generate a profit on the food and drinks you serve—after all of your operating expenses have been paid. Though the cuisine, atmosphere, and price points will vary by restaurant, they all have to follow the same economic formula. That basic knowledge, along with some understanding of accounting and a little bit of study, would enable one to evaluate and invest in any number of restaurants and restaurant chains, public or private. It's not all that complicated. Far more important is to honestly define what we do know and stick to those areas. Our circle of competence can be widened, but only slowly and over time. Mistakes are most often made when straying from this discipline. Where should we devote our limited time in life, to achieve the most success? So, the simple takeaway here is clear. If you want to improve your odds of success in life and business, then define the perimeter of your circle of competence, and operate inside. Over time, work to expand that circle

but never fool yourself about where it stands today, and never be afraid to say “I don’t know.”

II. Two Type of Knowledge: The Max Planck and Chauffeur Test

A. The Two Types of Knowledge: The Max Planck and Chauffeur Test: How to distinguish between the two types of knowledge: real knowledge and pretend knowledge.

- The first type of knowledge is real. It can’t be bought. It can’t be copied. If you want real knowledge you need to earn it. One is Planck knowledge, the people who really know. They’ve paid the dues, they have the aptitude. You are going to have the problem in your life of getting the responsibility into the people with the Planck knowledge and away from the people with the chauffeur knowledge. Real knowledge comes when people do the work. The problem is that it’s difficult to separate the two. This is the Batesian Mimicry problem. One way to tease out the difference between Planck and chauffeur knowledge is to ask them why.
- The second type of knowledge is copied. On the surface you know the answer but you lack the understanding to show your work. Then we’ve got chauffeur knowledge. They’ve learned the talk. They may have a big head of hair, they may have fine temper in the voice, they’ll make a hell of an impression. But in the end, all they have is chauffeur knowledge. I think I’ve just described practically every politician in the United States. We have the people who don’t do the work — they pretend. While they’ve learned to put on a good show, they lack understanding. They can’t answer questions that don’t rely on memorization. They can’t explain things without using jargon or vague terms. They have no idea how things interact. They can’t predict the consequences. The problem is that it’s difficult to separate the two. This is the Batesian Mimicry problem. One way to tease out the difference between Planck and chauffeur knowledge is to ask them why.
- How To Distinguish Real Knowledge and Fake Knowledge. With journalists, it is more difficult. Some have acquired true knowledge.

Often they are veteran reporters who have specialized for years in a clearly defined area. They make a serious effort to understand the complexity of a subject and to communicate it. They tend to write long articles that highlight a variety of cases and exceptions. The majority of journalists, however, fall into the category of chauffeur. They conjure up articles off the tops of their heads or, rather, from Google searches. Their texts are one-sided, short, and— often as compensation for their patchy knowledge. The same superficiality is present in business. The larger a company, the more the CEO is expected to possess “star quality.” Dedication, solemnity, and reliability are undervalued, at least at the top. Too often shareholders and business journalists seem to believe that showmanship will deliver better results, which is obviously not the case. One way to guard against this is to understand your circle of competence. Dobelli concludes with some advice worth taking to heart. Be on the lookout for chauffeur knowledge. Do not confuse the company spokesperson, the ringmaster, the newscaster, the schmoozer, the verbiage vendor, or the cliché generator with those who possess true knowledge. How do you recognize the difference? There is a clear indicator: True experts recognize the limits of what they know and what they do not know. If they find themselves outside their circle of competence, they keep quiet or simply say, “I don’t know.” This they utter unapologetically, even with a certain pride. From chauffeurs, we hear every line except this.

III. Batesian Mimicry Problem. Batesian Mimicry: Why Copycats Are Successful.

Mimic and the Real Thing:

- A. "There's two kinds of snakes you come across. There's the Texas Coral Snake, and the Mexican Milk Snake, and they both look exactly alike. The Texas Coral Snake is dangerous, it's venomous, it can kill you in a minute. The Mexican Milk Snake can't do anything to you; it's an impostor." How is it that these two look alike? It's due to a phenomenon called Batesian Mimicry.
- B. In the 1850s, the naturalist Henry Walter Bates found a certain set of butterflies who were clearly *not* of the same species but whose wings looked almost the same to the naked eye. After thinking it over, Bates eventually figured out what was going on: While the butterflies which were toxic to potential predators (the "models") were able to operate freely and relatively unmolested, there had also developed a "mimic" population of butterflies which wasn't toxic at all, yet still went untouched! In fact, biologists eventually figured out that the more toxic and dangerous the "model" was and the more frequently they appeared in the local population, the easier it was for its "mimics" to get by! Predators simply wouldn't take the risk of mixing up the two. If there aren't as many "models" around or they aren't that dangerous, the mimics have a harder time.
- C. This is a wonderful model, and in the practical world we live in, a similar phenomenon abounds: Copycats or "pretenders to the throne" are often very effective, very convincing "mimics" of the true champions. They dress the part, they talk the talk, and they know what buttons to push. But in the end, they are merely chauffeurs. We see a very Batesian effect at work: The more impressive the "model," the more effective its mimics can be in convincing people they too are impressive, and in all the same ways. But for every Warren Buffett (just one by our count), there has been many "future" Warren Buffett's. For every Steve Jobs, there have been many "next" Steve Jobs'. In fact, sometimes even just *appearances* can be quite convincing: now-disgraced Theranos founder Elizabeth Holmes was very fond of wearing a very Steve Jobsian black turtleneck outfit. Because they can be very convincing, we must be wise enough to watch out for Batesian mimicry

— even in ourselves. This brings up an interesting, at times paradoxical, question: Who can best tell the difference between a Coral Snake and its Mimics? The Coral Snake itself. The real thing knows a fake. It's worth taking the time to work on learning all the big ideas you can find, not just the ones you want to learn. In that search, you'll find a host of big winners you didn't even know existed.

9. Preparation:

- A. While we all hold an opinion on almost everything. Have I do the work required to have an opinion on any Subject? Never allow myself to have an opinion on anything that I don't know the other side's argument better than they do. The work required to have an opinion is very hard part, have I avoid it?
 - I. I have to do the reading.
 - II. I have to talk to competent people and understand their arguments.
 - III. Never try to be biased toward any of the side, but question both side of the argument.
 - IV. Do not support any side, until all the facts are put out there, clear and obvious.
 - V. Once known all the facts then analyse both sides of the argument like William Lane Craig.
 - VI. I have to think about the key variables and how they interact over time.
 - VII. I have to listen and chase down arguments that run counter to your views.
 - VIII. I have to think about how you might be fooling yourself.
 - IX. I have to see the issue from multiple perspectives.
 - X. I have to think.
 - XI. I need to become your most intelligent critic and have the intellectual honesty to kill some of your best-loved ideas.
 - XII. Be honest with yourself and open minded. ANALYSE both side of the argument logically and see which is true logically. Means has the clear terms, premises are true, and conclusion follows from premises.
 - XIII. Never say your opinion about anything that requires the analysis of the arguments and facts. Work very bery hard to have an opinion about anything.
 - XIV. Listen very carefully other side and use ancient method *state the opposition argument in my own words and ask him/her if the argument I

stated in my own words represents correctly their argument and if I UNDERSTOOD Correctly their arguments.

XV. Never use cheap shots to win argument, like logical fallacies.

XVI. Debate and discussion is not about just win at any cost, but let other person to think about your arguments and engage with them. Second reason never use in discussion cheap shots toward other person, but be civil. Third reason is win the debate and discussion. Fourth is find the truth.

B. For Affirmative and Negative Case:

- I. Read, analyse, Research, Syntopicon and Investigate Published Work.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of My own Arguments
- II. Read Opponents Books, Articles, Newspapers, Blogs. Reading Published work. What objections he would raise against the topic and prepare the responses for each of these points.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of opponent Arguments.
- III. Watch Video. Watching Videos of the opponent. What objections he would raise against the topic and prepare the responses for each of these points.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of My own Arguments.
- IV. Listen The recording that the opposition made, in which he addresses these issues.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of My own Arguments.
- V. Talk with People who are students in his class, who can tell me, privately, insights into his thinking and character.
- VI. If that sounds like a lot of work, just say, “I don’t have an opinion on that; why don’t you tell me how you got to have such a firm one? It sounds like I could learn something.”
- VII. Another way to get smarter, outside of reading, is to surround yourself with people who are not afraid to challenge your ideas. “Develop into a lifelong self-learner through voracious reading; cultivate curiosity and strive to become a little wiser every day.”

10. Compound Knowledge- Are The Resources I will Choose Concentrating On the Expiring Information or Compound Knowledge?

- I. Are on the Resources providing expiring information?
 - A. Will you care about what you're reading in a month? In a year? In five years?
 - B. Are you focused enough on the same thing to build cumulative knowledge or are you too spread out?
 - C. What do you spend time on that's likely to change in the next few years? What's not likely to change?
 - D. What would need to happen for you to stop outsourcing organisation of information to the computer?
- II. Signs of The Information in the resources are expiring
 - A. First, it's marketed to you.
 - B. Second, lacking details and nuance, it's easily digestible. This is why it's commonly telling you what happened, not why it happened or under what conditions it might happen again
 - C. Third, it won't be relevant in a month or a year. Expiring information is one reason I stopped reading most news. It's a false map.
- III. While most of us focus on consuming information that we won't care about next month, let alone next year, focus on knowledge and companies that change very, very slowly or not at all. And because the information he was learning changed slowly he could compound his knowledge over time.
- IV. Doing his own thinking and vacuums up the details. When we don't think for ourselves it's easy to put the blame on someone else, to "pass the buck" so to speak.
- V. When we consume information that doesn't expire or expires slowly; is very detailed; and we spend time thinking about it not passing the buck, we can match patterns. This is how you learn to see what other people are missing. The longer you do this, the more advantage you get.
- VI. Just like the rest of us, Buffett's dependent on information and knowledge to make great decisions. Unlike most of us, he has a great memory—perhaps because he's not trying to outsource his memory or thinking to others.
- VII. A lot of what the snowball is about the concept of learning, and creating, and the advantage of having the information and knowing it. When I came here today one

of the things that I was thinking is that what you do is so much at the intersection, because retrieving information is different from having it already in your head.

VIII. What you do is different. You work on manipulating how you use the information.

In fact, Warren Buffett and Charlie Munger have the files in their head. That's why they aren't really out there googling all the time looking for, trying to look stuff up, because they already know it.

IX. I think a lot of the work that you do here is helpful to the ordinary person, but Warren Buffett or Charlie Munger don't need it. At the same time, the lesson that they have, which is that learning yourself, making yourself as smart as you can is extremely valid, and not just relying on a library where you can look something up all the time, because a lot of times when you need to make a decision, and you need 50 pieces of information, you need to know it then.

11. The Art of Anticipation of Objections.

- A. Analyse My Arguments, and Scrutinise The arguments by using Rules of Reading.
- B. Analyse the arguments of the opponent. Scrutinise Their arguments by using Rules of Reading.
- C. Analyse My own arguments. Scrutinise My own arguments, and the potential Loopholes in the argument by Use Rules of Reading.
- D. Use Think, Logic, Strategem, Thinking models.
- E. Write.
- F. Prepare The responses to anticipated objections that, I think the opponent will bring up.
- G. Be intellectually Prepared. This means That I need to know my arguments, so well, that nothing new can surprise me. I would also invest lots of time in knowing and know better opposite side arguments. I would read both side of the arguments, and work Hard on analysing the arguments and evidence of both sides. Doing the work required to hold an opinion means you can argue against yourself better than others can. Only then can you say, "I can hold this view because I can't find anyone else who can argue better against my view." Great thinkers, like Charles Darwin, did the work. And it's one of the biggest reasons he's buried at Westminster Abbey. While we all hold an opinion on almost everything. Have I do the work required to have an opinion on any Subject? Never allow myself to have an opinion on anything that I don't know the other side's argument better than they do. The work required to have an opinion is very hard part, have I avoid it? If that sounds like a lot of work, just say, "I don't have an opinion on that; why don't you tell me how you got to have such a firm one? It sounds like I could learn something."
- H. Doing the work required to hold an opinion means you can argue against yourself better than others can. Only then can you say, "I can hold this view because I can't find anyone else who can argue better against my view." Great thinkers, like Charles Darwin, did the work. And it's one of the biggest reasons he's buried at Westminster Abbey.
- I. Doing the work counteracts our natural desire to seek out only information that confirms what we believe we know. When Darwin encountered opinions or facts that ran contrary to his ideas, he endeavored not only to listen but also not to rest

until he could either argue better than his challengers or understand how the fact fit. Darwin did the work. It's wasn't easy, but that's the point.

- J. Have the best work ethic on daily basis. This is everyday process, and try to figure it out, the strengths and weaknesses of my position and opposing person position, This leads to the True Confidence.
- K. As Per Kobe Bryant statement: Trivial things should not be taken your attention. The attentions should be focused on things that is very important. Anything outside of the most important things in life, you should not have time for. You Should love the challenge in life, and always be curious, if you can be at the top , as these greats in that area. Always focus on one thing and not multiple things, this gives an edge and advantage over other people, who focusing on multiple things in life. The World Becomes a library to you, to be better at your craft.: Everything you see whether TV show I saw, Books, Journals, I read, whether discussion, debate I listen, people I talk to. Everything was done to try to learn to become better at the craft your focusing. When you have this point of view, then the world becomes your library to help you to become better at the craft.
- L. I Always need to ask myself: Have I done the work required to have an opinion on any Subject? Never allow myself to have an opinion on anything that I don't know the other side's argument better than they do. The work required to have an opinion is very hard part, have I avoid it? If that sounds like a lot of work, just say, "I don't have an opinion on that; why don't you tell me how you got to have such a firm one? It sounds like I could learn something."
- M. I might need to Suspend my judgement and tell them that I do not have an opinion on this specific Topic.
- N. Never Under Prepare, but Vastly Over Prepare for the Opponent and their arguments and responses
- O. Spend years in preparation, take debate class at the college or university. You need to participate in debates. You need to have mock debates, where someone play role of your opponent, and then you respond to them. You need to do reading and learn how to flow the debates. How to construct affirmative case and negative case. You need to take time to prepare and have enormous preparation.
- P. Memorize the arguments for my case

12. When Dialogue, Discussion, Debate Takes A Place.

A. As Affirmative Speaker, you need to present Prima Facie Case for proposition that is under debate. Prima Facie Case will be one that will establish the truth of proposition you are defending. If I am defending proposition that God Exist, I will want to give 3-5 arguments leading to that Conclusion, that God Exists, and then I will lay those out with great clarity in my opening speech, and say this is the groundwork for the debate. I am not interested in talking about other issues for example if Christianity bad for society Then, I come back to those in every speech over and over again. The goal is to make opponent argue on your grounds. You do not go over to his grounds, and let your audience forget, your affirmative case, rather you reorganise opponent speech, so that you answer his objections in so far as they reply to your arguments, so you may answer them in a very different order than he gave them, because you will be seeing for example: now what answer or response did he have to the cosmological argument, I see two basic responses and then you deal with them.

- Make Briefs, where I have suitable objection, and then have two or three responses to those objections.
- Use The Brief During Exchange with the Opponent. File these Briefs into Folders, and spread These Manila Folders out in front of me on Desk, When I am interacting with the Opponent. Once the opponent Rises his point I just pull These briefs from these folders and never have to think on my feet because I am completely prepared. Key is never have to think on the feet to be so well prepared, that I would have my responses ready for anything he brings up.
- Quote Peer Review Scientific Articles on the topic in support the conclusions.

B. Take Notes While the Opposition is speaking:

- How To Take Notes- Flow Chart. By Taking Notes, I am sure that I am responding to my opponent's arguments and everything he brings up.

- I. Make 11-12 Columns on the Pad. Prepare the left column in advance of the communication, debate. The Left Column needs to be filled in, if you starting first. If not, then leave left column as blank.
- II. First Left Hand Column Are My Arguments.
- III. Second Left Hand Column are Opposition Arguments and Responses to My arguments.
- IV. Third Left Column are My Responses to the Opponent responses.
- V. Fourth Left Hand Column are My Rebuttal.
- VI. Fifth Left Hand Column are Opponent Rebuttal.
- VII. Sixth Left Hand Column are my Responses to the Opponent rebuttal.
- VIII. Seventh Left Hand Column is the Final My Rebuttal.
- IX. Eight Left Hand Column is The opponent Rebuttal.
- X. Ninth Left Hand Column is my closing statements.
- XI. Tenth Left Hand Column is the opponent closing statements.
- XII. Eleventh Left Hand Column is the Cross Examination.
 - My Answer.
 - Opponent Answer.
 - My response to the response of the opponent.

C. Always Remind the audience what are your three to five arguments and what are the responses of the opponent, if any to your arguments.

D. Always allow the opponent allow to lay out his argument without interruption.

E. Take the opponent arguments and put in my own words and correctly represent their argument carefully without misrepresentation.

F. Be Honest.

G. Be Open Minded.

H. Always from Your side be honest and rigorous exchange of arguments and counter Arguments from which me and opponent would benefit.

I. One of good technique is whenever you can quote an opponent against himself, this is powerful device. Have the manuscript, point to the footnote, cite the book, and the quotation and have the page number.

J. Never Take Cheap Shots at the Opponent.

- K. Encourage not just trust someone say so, but demand published peer reviewed articles in support of the positions that one take
- L. Always look at the reality of the situation, and do not let the emotion cloud the situation and the execution. Always be in the present and the moment.

Step 200-Letting The World Do The Work For You

1. Listen and Apply book
 - I. This Explains Everything_ Deep, Beautiful, and Elegant Theories of How the World Works
2. **The world never tells you that you're wrong; it only gives you outcomes.**
3. **Don't force. Don't resist. Have a beginner's mind. Let the world teach you.**
4. **Reality will do a lot of the work for us if we simply align with it. Most of the time we're simply adding friction because we want the world to work in the way we think it should.**
5. **If you don't see the world the way it is, you'll think it works in a way that it doesn't and make terrible mistakes. The key to getting what you want out of life is to identify how the world works and align yourself accordingly. This is hard because we think the world should work the way we see it. The word "should" is important. Because we think the world should work in a way that it doesn't, our approach is suboptimal. What the pupil must learn, if he learns anything at all, is that the world will do most of the work for you, provided you cooperate with it by identifying how it really works and aligning with those realities. If we do not let the world teach us, it teaches us a lesson. Joseph Tussman**
6. When an outcome is not what you want it to be, things get tough. You can ignore the result and continue to think that you're right. This protects your ego. It also carries the risk of your continuing to believe something that isn't true. Alternatively, you can calibrate your believability on the subject at hand by lowering the odds that you're right. For example, maybe you gave yourself an 85 out of 100 for the ability to hold a firm opinion on this subject, and now you lower your score to 75. If the world continues to provide undesirable outcomes, eventually you get the hint and change your beliefs. Finally, you can give up your opinions and just respond to the world as it is. This option is the hardest.
7. You do not create the way the world works, you can only align yourself with it. It takes a lot of work to align ourselves with reality. When we don't get the outcome we're seeking, the last place we look is inside ourselves. Instead, we blame others or

circumstances. If you want to align yourself with reality, you have to work at it and care about it. There are two keys to aligning yourself with how the world really works: accepting feedback and stopping bargaining.

- I. We let people, not results, guide our behavior. The world tries to tell us when we don't see it the way it is. The problem is we don't listen to the world. Instead, we let others tell us what's right and wrong, what works, and what doesn't. Common actions get common results. Most of our actions come from others. We want what they want. Even worse, we employ the same actions to get it. This isn't always wrong. If you're just starting, the quickest path to average is to copy. If you want better results than average, you're going to have to iterate. Doing something different means we might look like a fool, and we do not want to look like a fool. Iterating means trying something new, it means you might fail. Show me a person who's afraid to look bad, and I'll show you a person you can beat every time. If we do what everyone else is doing, we're going to get the same results that everyone else is getting. Different results demand different actions. If you can't really fail, you can't really succeed. Let results, not popularity, determine your actions. If you're doing something that doesn't get you the results you want, try something new. If you're doing something that seems to work, keep doing it. Consistently repeat successful actions.
- II. Bargaining with the world doesn't work. A lot of otherwise smart people know what they're doing isn't getting the results they want, but because they think the world *should* work in a way that it doesn't, they keep repeating them hoping for different results. If you are this person, see it for what it is, and change your actions. The feedback from the world is often painful. Often, it is this very pain that causes us to no longer delude ourselves with how the world should work and accept how it does work. If you can learn to accept the world for how it is, before suffering, you'll go faster and further. Outcome over ego. If you think you know how the world works but you're doing something that gets suboptimal results because it *should* work a different way, you don't really know how the world works. Rational people take feedback from the world. If you want to know how someone sees the world, look at their actions. In the end, it's all your fault. You are accountable for your outcomes. When you take responsibility for your outcomes, you naturally accept feedback from reality. When you get feedback from reality, you adjust your behavior.

- III. As Per Kobe Bryant statement: Trivial things should not be taken your attention. The attentions should be focused on things that is very important. Anything outside of the most important things in life, you should not have time for. You Should love the challenge in life, and always be curious, if you can be at the top , as these greats in that area. Always focus on one thing and not multiple things, this gives an edge and advantage over other people, who focusing on multiple things in life. The World Becomes a library to you, to be better at your craft.: Everything you see whether TV show I saw, Books, Journals, I read, whether discussion, debate I listen, people I talk to. Everything was done to try to learn to become better at the craft your focusing. When you have this point of you, then the world becomes your library to help you to become better at the craft.
- IV. Have the best work ethic on daily basis. This is everyday process, and try to figure it out, the strengths and weaknesses of my position and opposing person position.
- V. Always look at the reality of the situation, and do not let the emotion cloud the situation and the execution. Always be in the present and the moment.
- VI. If you understand the world as it really is, not as you'd wish it to be, you will begin to make better decisions almost immediately. Once you start making better decisions the results compound. Better initial decisions free up your time, reduce your stress, allowing you to spend more time with your family and leave your competition in the dust.
- VII. How can we best understand the world as it is? Acquiring knowledge can be a very daunting task. If you think of the mind as a toolbox, we're only as good as the tools at our disposal. A carpenter doesn't show up to work with an empty toolbox. Not only do they want as many tools in their toolbox as possible, but they want to know how to use them. Having more tools and the knowledge of how to use them means they can tackle more problems. Try as we might, we cannot build a house with only a hammer. If you're a knowledge worker, you're a carpenter. But your tools aren't bought at a store and they don't come in a red box that you carry around. Mental tools are the big ideas from multiple disciplines, and we store them in our mind. And if we have a lot of tools and the knowledge required to wield them properly, we can start to synthesize how the world works and make better decisions when confronted with problems.
- VIII. This is how we understand and deal with reality. The tools you put into your toolbox are Mental Models. Mental models are a framework for understanding

how the world really works. They help you grasp new ideas quickly, identify patterns before anyone else and shift your perspective with ease. Mental Models allow us to make better decisions, scramble out of bad situations, and think critically. If you want to understand reality you must look at a problem in multiple dimensions — how could it be otherwise? Getting to this level of understanding requires having a lot of tools and knowing how to use them. You knew there was a hitch right? We need to change our fast-food diet of information consumption and adopt the healthier diet of knowledge that changes slowly over time. While changing diets isn't easy, it can be incredibly rewarding: more time, less stress, and being better at your job. The costs, however, are short term pain for long-term gain. You must change how you think.

- IX. 2nd Order Thinking. One example of a model we can immediately conceptualize and use to improve our ability to make better decisions is something we can borrow from ecology called second-order thinking. The simple way to conceptualize this is to ask yourself "If I do X, what will happen *after* that?". I sum this up using the ecologist Garrett Hardin's simple question: "And then what?" A lot of people forget about higher order effects — second and third-order effects or higher. I've been in a lot of meetings where decisions are made and very few people think to the second level, let alone the third. Rather, what typically happens is called first conclusion bias. The brain shuts down and stops thinking at the first idea that comes to mind that seems to address the problem as you understand it. We don't often realize that our first thoughts are usually not even our own thoughts. They usually belong to someone else. We understand the sound-byte but we haven't done the hard work of real thinking. After we reach the first conclusion, our minds often shut down. We don't seek evidence that would contradict our conclusion. We don't ask ourselves what the likely result of this solution would be — we don't ask ourselves "And then what?" We don't ask what other solutions might be even *more* optimal. For example, consider a hypothetical organization that decides to change their incentive systems. They come up with a costly new system that requires substantial changes to the current system. Only they don't consider (or even understand) the problems that the *new* system is likely to create. It's possible they've created more problems than they've solved — only now there are *different* problems they must put their head down to solve. Optically, they "reorganize their incentive programs," but practically, they've simply expended energy to stay in place. Another, perhaps more complicated,

example is when a salesman comes into a company and offers you a software program he claims will lower your operating costs and increase your profits. He's got all these beautiful charts on how much more competitive you'll be and how it will improve everything. This is exactly what you need because your compensation is based on increasing profits. You're sold. Then second-order thinking kicks in and you dare to ask how much of those cost savings are going to go to you and how much will eventually end up benefits enjoyed by customers? To a large extent, that depends on the business you're in. However, you can be damn sure the salesman is now knocking on your competitor's door and telling them you just bought their product and if they want to remain competitive they better purchase it too. Eventually, you all have the new software and no one is truly better off. Thus, in the manner of a crowd of people standing on their tip-toes at a parade, all competitors spend the money but none of them win: The salesman wins and the customer wins. We know, thanks to people like Garrett Hardin, Howard Marks, Charlie Munger, Peter Kaufman, and disciplines like ecology, that there are second and third-order effects. This is how the world really works. It just isn't always a comfortable reality. Understanding how the world works isn't easy and it shouldn't be. It's hard work. If it were easy, everyone would do it. And it's not for everyone. Sometimes, if your goal is to maximize utility, you should focus on getting very, very good in a narrow area and becoming an expert, accepting that you will make many mistakes outside of that domain. But for most, it's extremely helpful to understand the forces at play outside of their narrow area of expertise. Because when you think about it, how could reality be anything other than a synthesis of multiple factors? How could it possibly be otherwise?

- X. When our mental models line up with reality, they help us avoid problems. However, they also cause problems when they don't line up with reality as we think something that isn't true.
- XI. We must be open to other perspectives if we truly want to understand the results of our actions. Despite feeling that we've got all the information, if we're on the ship, the fish in the ocean has more he can share. The second flaw is ego. Many of us tend to have too much invested in our opinions of ourselves to see the world's feedback—the feedback we need to update our beliefs about reality. This creates a profound ignorance that keeps us banging our head against the wall over and over again. Our inability to learn from the world because of our ego happens for many reasons, but two are worth mentioning here. First, we're so

afraid about what others will say about us that we fail to put our ideas out there and subject them to criticism. This way we can always be right. Second, if we do put our ideas out there and they are criticized, our ego steps in to protect us. We become invested in defending instead of upgrading our ideas. The third flaw is distance. The further we are from the results of our decisions, the easier it is to keep our current views rather than update them. When you put your hand on a hot stove, you quickly learn the natural consequence. You pay the price for your mistakes. Since you are a pain avoiding creature, you update your view. Before you touch another stove, you check to see if it's hot. But you don't just learn a micro lesson that applies in one situation. Instead, you draw a general abstraction, one that tells you to check before touching anything that could potentially be hot. Organizations over a certain size often remove us from the direct consequences of our decisions. When we make decisions that other people carry out, we are one or more levels removed and may not immediately be able to update our understanding.

Step 201-Use Thinking, Logic, Mental Tools, Thinking Tools.

1. **Go to the Rules of Reading Part 7: Thinking, Logic and Mental Model For Deep Work or Deep Study, Or Bible Study**
2. Listen, Follow and Apply **Thinking, Logic and Mental Model PART 7**
Part 7: Thinking, Logic and Mental Model For Deep Work or Deep Study, Or Bible Study
 1. **Step 57- Slow Down. Pages 1061-1063.**
 2. **Step 58- NOT MULTITASK. Pages 1064.**
 3. **Step 59-You Have Required To Do The Work For Thinking and Applying Mental Tool Models. Pages 1065-1080.**
 4. **Step 60-Why Critical Thinking, Logic, Thinking and Mental Tools Are Important? Pages 1081-1083.**
 5. **Step 61-Intradisciplinary Thinking. Pages 1084-1125.**
 6. **Step 62-Multidisciplinary Thinking. Pages 1126-1168.**
 7. **Step 63-CrossDisciplinary Thinking. Pages 1169-1211.**
 8. **Step 64-Interdisciplinary Thinking. Pages 1212-1254.**
 9. **Step 65-Transdisciplinary Thinking. Pages 1255-1298.**
 10. **Step 66-Journaling. Pages 1299.**
 11. **Step 67-Letting The World Do The Work For You. Pages 1300-1305.**
 12. **Step 68-Journaling. Pages 1306.**
 13. **Step 69-Letting The World Do The Work For You. Pages 1307-1312.**

Part 31: Situational Awareness.

Step 202 - Books On Situational Awareness

1. **Listen, Follow And Apply Rules of Reading Part 1 to 22, before looking into Situational Awareness.**
2. **Listen, Follow and Apply the following Books.**
 - A. Hindsight 23 situational awareness.
 - B. 80/20 Principle.
 - C. Eat that frog.
 - D. How to speak how to listen.
 - E. Situational awareness Matters.
 - F. Advanced situational awareness.
 - G. Situational awareness.
 - H. **The ultimate situational survival guide _ self-reliance strategies for a dangerous world**

Step 203-You Have Required To Do The Work

1. When Give Opinion on Anything, Do Not Be so Angry and Mean to Others.
2. People Need To Stop Doing By Coming Unprepared To Give Opinion On Any Subject, Without Having Good Idea Of The Literature, and Arguments Written on Topic and Theme Available To Them. The people coming unprepared and not doing any Hard Work To Have an Opinion On The Subject or Topic. When People Coming Overconfidence, which could be resulting in Lack of Preparation, Which Could Lead That Your Position can be Destroyed with Ease. They simply won't do the work required. It's easy to come home, sit on the couch, watch TV, and zone out until bedtime rolls around. But that's not going to help you get smarter.
 - A. People Who Do Not Put The Required Work: The first thing they always do is tell you what they think. When someone has an opinion about everything, they want to share it with you. They often tout stats and research as if they had an imaginary checklist of facts they need to be able to rattle off to establish themselves as an expert in a field they actually know very little about. Because they have an opinion on everything, they are quick to judge others – for their lack of opinions, for their lack of knowledge, for their lack of outrage, and the list goes on.
 - B. People who have opinions about everything barf so much noise that it's hard to find the signal. Your brain has to work overtime to figure out if they did the work to come up with their opinions themselves or if they're simply regurgitating some oped in a newspaper. Over time, opinionated people also end up in their own prisons and they try to take you with them.
 - C. The problem comes from how we see the world. Our opinions are often rooted in how we think the world should work, according to our morals, values, and principles. If we see the world through the lens of our opinions, much of what happens will not agree with us. This is feedback, and how we respond to this feedback is key.

3. How to Get Smarter Read. A lot. Warren Buffett says, "I just sit in my office and read all day." What does that mean? He estimates that he spends 80% of his working day reading and thinking. When asked how to get smarter, Buffett once held up stacks of paper and said, "Read 500 pages like this every week. That's how knowledge builds up, like compound interest." All of us can build our knowledge, but most of us won't put in the effort. "Go to bed smarter than when you woke up."
4. How Long Does it Take To Prepare:
 - A. Depend on the topic and opponent, and how much he's written.
 - B. If the opponent nothing published, then there was very little preparation to be made because I simply didn't know what to expect.
 - C. On the other hand, if the opponent has published lots of written work and have some videos. Read and what his written and videos and prepare the summaries articles, videos, and have sense where he is coming from. This can take Weeks or Months.

5. Before Preparation. The difference between the people who do the work and the people who just reel off memorized opinions is huge. When you do the work, you can answer the next question. You know when to follow the rules and when they'll get you in trouble. When I did my postgraduate I was surrounded by people who could answer the test questions. They got good grades — actually, they got *great* grades but an odd thing happened after school: a lot of those people couldn't apply their knowledge to problems they hadn't seen before. They were chauffeurs — they knew the memorized answer. They couldn't answer the next question. We're all chauffeurs in some aspects of our lives. This is why understanding your circle of competence is so critical to living a rational life.

I. Circle of Competence:

A. **Circle Of Competence**-Understanding my Circle of Competence helps to avoid problems, identify opportunities for improvement and learn from Others. Circle of Competence is simple: Each of us, through experience or study, has built up useful knowledge on certain areas of the world. Some areas are understood by most of us, while some areas require a lot more specialty to evaluate. For example, most of us have a basic understanding of the economics of a restaurant: You rent or buy space, spend money to outfit the place and then hire employees to seat, serve, cook, and clean. (And, if you don't want to do it yourself, manage.) From there, it's a matter of generating enough traffic and setting the appropriate prices to generate a profit on the food and drinks you serve—after all of your operating expenses have been paid. Though the cuisine, atmosphere, and price points will vary by restaurant, they all have to follow the same economic formula. That basic knowledge, along with some understanding of accounting and a little bit of study, would enable one to evaluate and invest in any number of restaurants and restaurant chains, public or private. It's not all that complicated. Far more important is to honestly define what we do know and stick to those areas. Our circle of competence can be widened, but only slowly and over time. Mistakes are most often made when straying from this discipline. Where should we devote our limited time in life, to achieve the most success? So, the simple takeaway here is clear. If you want to improve your odds of success in life and business, then define the perimeter of your circle of competence, and operate inside. Over time, work to expand that circle

but never fool yourself about where it stands today, and never be afraid to say “I don’t know.”

II. Two Type of Knowledge: The Max Planck and Chauffeur Test

A. The Two Types of Knowledge: The Max Planck and Chauffeur Test: How to distinguish between the two types of knowledge: real knowledge and pretend knowledge.

- The first type of knowledge is real. It can’t be bought. It can’t be copied. If you want real knowledge you need to earn it. One is Planck knowledge, the people who really know. They’ve paid the dues, they have the aptitude. You are going to have the problem in your life of getting the responsibility into the people with the Planck knowledge and away from the people with the chauffeur knowledge. Real knowledge comes when people do the work. The problem is that it’s difficult to separate the two. This is the Batesian Mimicry problem. One way to tease out the difference between Planck and chauffeur knowledge is to ask them why.
- The second type of knowledge is copied. On the surface you know the answer but you lack the understanding to show your work. Then we’ve got chauffeur knowledge. They’ve learned the talk. They may have a big head of hair, they may have fine temper in the voice, they’ll make a hell of an impression. But in the end, all they have is chauffeur knowledge. I think I’ve just described practically every politician in the United States. We have the people who don’t do the work — they pretend. While they’ve learned to put on a good show, they lack understanding. They can’t answer questions that don’t rely on memorization. They can’t explain things without using jargon or vague terms. They have no idea how things interact. They can’t predict the consequences. The problem is that it’s difficult to separate the two. This is the Batesian Mimicry problem. One way to tease out the difference between Planck and chauffeur knowledge is to ask them why.
- How To Distinguish Real Knowledge and Fake Knowledge. With journalists, it is more difficult. Some have acquired true knowledge.

Often they are veteran reporters who have specialized for years in a clearly defined area. They make a serious effort to understand the complexity of a subject and to communicate it. They tend to write long articles that highlight a variety of cases and exceptions. The majority of journalists, however, fall into the category of chauffeur. They conjure up articles off the tops of their heads or, rather, from Google searches. Their texts are one-sided, short, and— often as compensation for their patchy knowledge. The same superficiality is present in business. The larger a company, the more the CEO is expected to possess “star quality.” Dedication, solemnity, and reliability are undervalued, at least at the top. Too often shareholders and business journalists seem to believe that showmanship will deliver better results, which is obviously not the case. One way to guard against this is to understand your circle of competence. Dobelli concludes with some advice worth taking to heart. Be on the lookout for chauffeur knowledge. Do not confuse the company spokesperson, the ringmaster, the newscaster, the schmoozer, the verbiage vendor, or the cliché generator with those who possess true knowledge. How do you recognize the difference? There is a clear indicator: True experts recognize the limits of what they know and what they do not know. If they find themselves outside their circle of competence, they keep quiet or simply say, “I don’t know.” This they utter unapologetically, even with a certain pride. From chauffeurs, we hear every line except this.

III. Batesian Mimicry Problem. Batesian Mimicry: Why Copycats Are Successful.

Mimic and the Real Thing:

- A. "There's two kinds of snakes you come across. There's the Texas Coral Snake, and the Mexican Milk Snake, and they both look exactly alike. The Texas Coral Snake is dangerous, it's venomous, it can kill you in a minute. The Mexican Milk Snake can't do anything to you; it's an impostor." How is it that these two look alike? It's due to a phenomenon called Batesian Mimicry.
- B. In the 1850s, the naturalist Henry Walter Bates found a certain set of butterflies who were clearly *not* of the same species but whose wings looked almost the same to the naked eye. After thinking it over, Bates eventually figured out what was going on: While the butterflies which were toxic to potential predators (the "models") were able to operate freely and relatively unmolested, there had also developed a "mimic" population of butterflies which wasn't toxic at all, yet still went untouched! In fact, biologists eventually figured out that the more toxic and dangerous the "model" was and the more frequently they appeared in the local population, the easier it was for its "mimics" to get by! Predators simply wouldn't take the risk of mixing up the two. If there aren't as many "models" around or they aren't that dangerous, the mimics have a harder time.
- C. This is a wonderful model, and in the practical world we live in, a similar phenomenon abounds: Copycats or "pretenders to the throne" are often very effective, very convincing "mimics" of the true champions. They dress the part, they talk the talk, and they know what buttons to push. But in the end, they are merely chauffeurs. We see a very Batesian effect at work: The more impressive the "model," the more effective its mimics can be in convincing people they too are impressive, and in all the same ways. But for every Warren Buffett (just one by our count), there has been many "future" Warren Buffett's. For every Steve Jobs, there have been many "next" Steve Jobs'. In fact, sometimes even just *appearances* can be quite convincing: now-disgraced Theranos founder Elizabeth Holmes was very fond of wearing a very Steve Jobsian black turtleneck outfit. Because they can be very convincing, we must be wise enough to watch out for Batesian mimicry

— even in ourselves. This brings up an interesting, at times paradoxical, question: Who can best tell the difference between a Coral Snake and its Mimics? The Coral Snake itself. The real thing knows a fake. It's worth taking the time to work on learning all the big ideas you can find, not just the ones you want to learn. In that search, you'll find a host of big winners you didn't even know existed.

6. Preparation:

- A. While we all hold an opinion on almost everything. Have I do the work required to have an opinion on any Subject? Never allow myself to have an opinion on anything that I don't know the other side's argument better than they do. The work required to have an opinion is very hard part, have I avoid it?
 - I. I have to do the reading.
 - II. I have to talk to competent people and understand their arguments.
 - III. Never try to be biased toward any of the side, but question both side of the argument.
 - IV. Do not support any side, until all the facts are put out there, clear and obvious.
 - V. Once known all the facts then analyse both sides of the argument like William Lane Craig.
 - VI. I have to think about the key variables and how they interact over time.
 - VII. I have to listen and chase down arguments that run counter to your views.
 - VIII. I have to think about how you might be fooling yourself.
 - IX. I have to see the issue from multiple perspectives.
 - X. I have to think.
 - XI. I need to become your most intelligent critic and have the intellectual honesty to kill some of your best-loved ideas.
 - XII. Be honest with yourself and open minded. ANALYSE both side of the argument logically and see which is true logically. Means has the clear terms, premises are true, and conclusion follows from premises.
 - XIII. Never say your opinion about anything that requires the analysis of the arguments and facts. Work very bery hard to have an opinion about anything.
 - XIV. Listen very carefully other side and use ancient method *state the opposition argument in my own words and ask him/her if the argument I

stated in my own words represents correctly their argument and if I UNDERSTOOD Correctly their arguments.

XV. Never use cheap shots to win argument, like logical fallacies.

XVI. Debate and discussion is not about just win at any cost, but let other person to think about your arguments and engage with them. Second reason never use in discussion cheap shots toward other person, but be civil. Third reason is win the debate and discussion. Fourth is find the truth.

B. For Affirmative and Negative Case:

- I. Read, analyse, Research, Syntopicon and Investigate Published Work.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of My own Arguments
- II. Read Opponents Books, Articles, Newspapers, Blogs. Reading Published work. What objections he would raise against the topic and prepare the responses for each of these points.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of opponent Arguments.
- III. Watch Video. Watching Videos of the opponent. What objections he would raise against the topic and prepare the responses for each of these points.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of My own Arguments.
- IV. Listen The recording that the opposition made, in which he addresses these issues.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of My own Arguments.
- V. Talk with People who are students in his class, who can tell me, privately, insights into his thinking and character.
- VI. If that sounds like a lot of work, just say, “I don’t have an opinion on that; why don’t you tell me how you got to have such a firm one? It sounds like I could learn something.”
- VII. Another way to get smarter, outside of reading, is to surround yourself with people who are not afraid to challenge your ideas. “Develop into a lifelong self-learner through voracious reading; cultivate curiosity and strive to become a little wiser every day.”

7. Compound Knowledge- Are The Resources I will Choose Concentrating On the Expiring Information or Compound Knowledge?

- I. Are on the Resources providing expiring information?
 - A. Will you care about what you're reading in a month? In a year? In five years?
 - B. Are you focused enough on the same thing to build cumulative knowledge or are you too spread out?
 - C. What do you spend time on that's likely to change in the next few years? What's not likely to change?
 - D. What would need to happen for you to stop outsourcing organisation of information to the computer?
- II. Signs of The Information in the resources are expiring
 - A. First, it's marketed to you.
 - B. Second, lacking details and nuance, it's easily digestible. This is why it's commonly telling you what happened, not why it happened or under what conditions it might happen again
 - C. Third, it won't be relevant in a month or a year. Expiring information is one reason I stopped reading most news. It's a false map.
- III. While most of us focus on consuming information that we won't care about next month, let alone next year, focus on knowledge and companies that change very, very slowly or not at all. And because the information he was learning changed slowly he could compound his knowledge over time.
- IV. Doing his own thinking and vacuums up the details. When we don't think for ourselves it's easy to put the blame on someone else, to "pass the buck" so to speak.
- V. When we consume information that doesn't expire or expires slowly; is very detailed; and we spend time thinking about it not passing the buck, we can match patterns. This is how you learn to see what other people are missing. The longer you do this, the more advantage you get.
- VI. Just like the rest of us, Buffett's dependent on information and knowledge to make great decisions. Unlike most of us, he has a great memory—perhaps because he's not trying to outsource his memory or thinking to others.
- VII. A lot of what the snowball is about the concept of learning, and creating, and the advantage of having the information and knowing it. When I came here today one

of the things that I was thinking is that what you do is so much at the intersection, because retrieving information is different from having it already in your head.

VIII. What you do is different. You work on manipulating how you use the information.

In fact, Warren Buffett and Charlie Munger have the files in their head. That's why they aren't really out there googling all the time looking for, trying to look stuff up, because they already know it.

IX. I think a lot of the work that you do here is helpful to the ordinary person, but Warren Buffett or Charlie Munger don't need it. At the same time, the lesson that they have, which is that learning yourself, making yourself as smart as you can is extremely valid, and not just relying on a library where you can look something up all the time, because a lot of times when you need to make a decision, and you need 50 pieces of information, you need to know it then.

8. The Art of Anticipation of Objections.

- A. Analyse My Arguments, and Scrutinise The arguments by using Rules of Reading.
- B. Analyse the arguments of the opponent. Scrutinise Their arguments by using Rules of Reading.
- C. Analyse My own arguments. Scrutinise My own arguments, and the potential Loopholes in the argument by Use Rules of Reading.
- D. Use Think, Logic, Strategem, Thinking models.
- E. Write.
- F. Prepare The responses to anticipated objections that, I think the opponent will bring up.
- G. Be intellectually Prepared. This means That I need to know my arguments, so well, that nothing new can surprise me. I would also invest lots of time in knowing and know better opposite side arguments. I would read both side of the arguments, and work Hard on analysing the arguments and evidence of both sides. Doing the work required to hold an opinion means you can argue against yourself better than others can. Only then can you say, "I can hold this view because I can't find anyone else who can argue better against my view." Great thinkers, like Charles Darwin, did the work. And it's one of the biggest reasons he's buried at Westminster Abbey. While we all hold an opinion on almost everything. Have I do the work required to have an opinion on any Subject? Never allow myself to have an opinion on anything that I don't know the other side's argument better than they do. The work required to have an opinion is very hard part, have I avoid it? If that sounds like a lot of work, just say, "I don't have an opinion on that; why don't you tell me how you got to have such a firm one? It sounds like I could learn something."
- H. Doing the work required to hold an opinion means you can argue against yourself better than others can. Only then can you say, "I can hold this view because I can't find anyone else who can argue better against my view." Great thinkers, like Charles Darwin, did the work. And it's one of the biggest reasons he's buried at Westminster Abbey.
- I. Doing the work counteracts our natural desire to seek out only information that confirms what we believe we know. When Darwin encountered opinions or facts that ran contrary to his ideas, he endeavored not only to listen but also not to rest

until he could either argue better than his challengers or understand how the fact fit. Darwin did the work. It's wasn't easy, but that's the point.

- J. Have the best work ethic on daily basis. This is everyday process, and try to figure it out, the strengths and weaknesses of my position and opposing person position, This leads to the True Confidence.
- K. As Per Kobe Bryant statement: Trivial things should not be taken your attention. The attentions should be focused on things that is very important. Anything outside of the most important things in life, you should not have time for. You Should love the challenge in life, and always be curious, if you can be at the top , as these greats in that area. Always focus on one thing and not multiple things, this gives an edge and advantage over other people, who focusing on multiple things in life. The World Becomes a library to you, to be better at your craft.: Everything you see whether TV show I saw, Books, Journals, I read, whether discussion, debate I listen, people I talk to. Everything was done to try to learn to become better at the craft your focusing. When you have this point of view, then the world becomes your library to help you to become better at the craft.
- L. I Always need to ask myself: Have I done the work required to have an opinion on any Subject? Never allow myself to have an opinion on anything that I don't know the other side's argument better than they do. The work required to have an opinion is very hard part, have I avoid it? If that sounds like a lot of work, just say, "I don't have an opinion on that; why don't you tell me how you got to have such a firm one? It sounds like I could learn something."
- M. I might need to Suspend my judgement and tell them that I do not have an opinion on this specific Topic.
- N. Never Under Prepare, but Vastly Over Prepare for the Opponent and their arguments and responses
- O. Spend years in preparation, take debate class at the college or university. You need to participate in debates. You need to have mock debates, where someone play role of your opponent, and then you respond to them. You need to do reading and learn how to flow the debates. How to construct affirmative case and negative case. You need to take time to prepare and have enormous preparation.
- P. Memorize the arguments for my case

9. When Dialogue, Discussion, Debate Takes A Place.

A. As Affirmative Speaker, you need to present Prima Facie Case for proposition that is under debate. Prima Facie Case will be one that will establish the truth of proposition you are defending. If I am defending proposition that God Exist, I will want to give 3-5 arguments leading to that Conclusion, that God Exists, and then I will lay those out with great clarity in my opening speech, and say this is the groundwork for the debate. I am not interested in talking about other issues for example if Christianity bad for society Then, I come back to those in every speech over and over again. The goal is to make opponent argue on your grounds. You do not go over to his grounds, and let your audience forget, your affirmative case, rather you reorganise opponent speech, so that you answer his objections in so far as they reply to your arguments, so you may answer them in a very different order than he gave them, because you will be seeing for example: now what answer or response did he have to the cosmological argument, I see two basic responses and then you deal with them.

- Make Briefs, where I have suitable objection, and then have two or three responses to those objections.
- Use The Brief During Exchange with the Opponent. File these Briefs into Folders, and spread These Manila Folders out in front of me on Desk, When I am interacting with the Opponent. Once the opponent Rises his point I just pull These briefs from these folders and never have to think on my feet because I am completely prepared. Key is never have to think on the feet to be so well prepared, that I would have my responses ready for anything he brings up.
- Quote Peer Review Scientific Articles on the topic in support the conclusions.

B. Take Notes While the Opposition is speaking:

- How To Take Notes- Flow Chart. By Taking Notes, I am sure that I am responding to my opponent's arguments and everything he brings up.

- I. Make 11-12 Columns on the Pad. Prepare the left column in advance of the communication, debate. The Left Column needs to be filled in, if you starting first. If not, then leave left column as blank.
- II. First Left Hand Column Are My Arguments.
- III. Second Left Hand Column are Opposition Arguments and Responses to My arguments.
- IV. Third Left Column are My Responses to the Opponent responses.
- V. Fourth Left Hand Column are My Rebuttal.
- VI. Fifth Left Hand Column are Opponent Rebuttal.
- VII. Sixth Left Hand Column are my Responses to the Opponent rebuttal.
- VIII. Seventh Left Hand Column is the Final My Rebuttal.
- IX. Eight Left Hand Column is The opponent Rebuttal.
- X. Ninth Left Hand Column is my closing statements.
- XI. Tenth Left Hand Column is the opponent closing statements.
- XII. Eleventh Left Hand Column is the Cross Examination.
 - My Answer.
 - Opponent Answer.
 - My response to the response of the opponent.

- C. Always Remind the audience what are your three to five arguments and what are the responses of the opponent, if any to your arguments.
- D. Always allow the opponent allow to lay out his argument without interruption.
- E. Take the opponent arguments and put in my own words and correctly represent their argument carefully without misrepresentation.
- F. Be Honest.
- G. Be Open Minded.
- H. Always from Your side be honest and rigorous exchange of arguments and counter Arguments from which me and opponent would benefit.
- I. One of good technique is whenever you can quote an opponent against himself, this is powerful device. Have the manuscript, point to the footnote, cite the book, and the quotation and have the page number.
- J. Never Take Cheap Shots at the Opponent.

- K. Encourage not just trust someone say so, but demand published peer reviewed articles in support of the positions that one take
- L. Always look at the reality of the situation, and do not let the emotion cloud the situation and the execution. Always be in the present and the moment.

Step 204-Letting The World Do The Work For You

1. Listen and Apply book
 - I. This Explains Everything_ Deep, Beautiful, and Elegant Theories of How the World Works
2. **The world never tells you that you're wrong; it only gives you outcomes.**
3. **Don't force. Don't resist. Have a beginner's mind. Let the world teach you.**
4. **Reality will do a lot of the work for us if we simply align with it. Most of the time we're simply adding friction because we want the world to work in the way we think it should.**
5. **If you don't see the world the way it is, you'll think it works in a way that it doesn't and make terrible mistakes. The key to getting what you want out of life is to identify how the world works and align yourself accordingly. This is hard because we think the world should work the way we see it. The word "should" is important. Because we think the world should work in a way that it doesn't, our approach is suboptimal. What the pupil must learn, if he learns anything at all, is that the world will do most of the work for you, provided you cooperate with it by identifying how it really works and aligning with those realities. If we do not let the world teach us, it teaches us a lesson. Joseph Tussman**
6. When an outcome is not what you want it to be, things get tough. You can ignore the result and continue to think that you're right. This protects your ego. It also carries the risk of your continuing to believe something that isn't true. Alternatively, you can calibrate your believability on the subject at hand by lowering the odds that you're right. For example, maybe you gave yourself an 85 out of 100 for the ability to hold a firm opinion on this subject, and now you lower your score to 75. If the world continues to provide undesirable outcomes, eventually you get the hint and change your beliefs. Finally, you can give up your opinions and just respond to the world as it is. This option is the hardest.
7. You do not create the way the world works, you can only align yourself with it. It takes a lot of work to align ourselves with reality. When we don't get the outcome we're seeking, the last place we look is inside ourselves. Instead, we blame others or

circumstances. If you want to align yourself with reality, you have to work at it and care about it. There are two keys to aligning yourself with how the world really works: accepting feedback and stopping bargaining.

- I. We let people, not results, guide our behavior. The world tries to tell us when we don't see it the way it is. The problem is we don't listen to the world. Instead, we let others tell us what's right and wrong, what works, and what doesn't. Common actions get common results. Most of our actions come from others. We want what they want. Even worse, we employ the same actions to get it. This isn't always wrong. If you're just starting, the quickest path to average is to copy. If you want better results than average, you're going to have to iterate. Doing something different means we might look like a fool, and we do not want to look like a fool. Iterating means trying something new, it means you might fail. Show me a person who's afraid to look bad, and I'll show you a person you can beat every time. If we do what everyone else is doing, we're going to get the same results that everyone else is getting. Different results demand different actions. If you can't really fail, you can't really succeed. Let results, not popularity, determine your actions. If you're doing something that doesn't get you the results you want, try something new. If you're doing something that seems to work, keep doing it. Consistently repeat successful actions.
- II. Bargaining with the world doesn't work. A lot of otherwise smart people know what they're doing isn't getting the results they want, but because they think the world *should* work in a way that it doesn't, they keep repeating them hoping for different results. If you are this person, see it for what it is, and change your actions. The feedback from the world is often painful. Often, it is this very pain that causes us to no longer delude ourselves with how the world should work and accept how it does work. If you can learn to accept the world for how it is, before suffering, you'll go faster and further. Outcome over ego. If you think you know how the world works but you're doing something that gets suboptimal results because it *should* work a different way, you don't really know how the world works. Rational people take feedback from the world. If you want to know how someone sees the world, look at their actions. In the end, it's all your fault. You are accountable for your outcomes. When you take responsibility for your outcomes, you naturally accept feedback from reality. When you get feedback from reality, you adjust your behavior.

- III. As Per Kobe Bryant statement: Trivial things should not be taken your attention. The attentions should be focused on things that is very important. Anything outside of the most important things in life, you should not have time for. You Should love the challenge in life, and always be curious, if you can be at the top , as these greats in that area. Always focus on one thing and not multiple things, this gives an edge and advantage over other people, who focusing on multiple things in life. The World Becomes a library to you, to be better at your craft.: Everything you see whether TV show I saw, Books, Journals, I read, whether discussion, debate I listen, people I talk to. Everything was done to try to learn to become better at the craft your focusing. When you have this point of you, then the world becomes your library to help you to become better at the craft.
- IV. Have the best work ethic on daily basis. This is everyday process, and try to figure it out, the strengths and weaknesses of my position and opposing person position.
- V. Always look at the reality of the situation, and do not let the emotion cloud the situation and the execution. Always be in the present and the moment.
- VI. If you understand the world as it really is, not as you'd wish it to be, you will begin to make better decisions almost immediately. Once you start making better decisions the results compound. Better initial decisions free up your time, reduce your stress, allowing you to spend more time with your family and leave your competition in the dust.
- VII. How can we best understand the world as it is? Acquiring knowledge can be a very daunting task. If you think of the mind as a toolbox, we're only as good as the tools at our disposal. A carpenter doesn't show up to work with an empty toolbox. Not only do they want as many tools in their toolbox as possible, but they want to know how to use them. Having more tools and the knowledge of how to use them means they can tackle more problems. Try as we might, we cannot build a house with only a hammer. If you're a knowledge worker, you're a carpenter. But your tools aren't bought at a store and they don't come in a red box that you carry around. Mental tools are the big ideas from multiple disciplines, and we store them in our mind. And if we have a lot of tools and the knowledge required to wield them properly, we can start to synthesize how the world works and make better decisions when confronted with problems.
- VIII. This is how we understand and deal with reality. The tools you put into your toolbox are Mental Models. Mental models are a framework for understanding

how the world really works. They help you grasp new ideas quickly, identify patterns before anyone else and shift your perspective with ease. Mental Models allow us to make better decisions, scramble out of bad situations, and think critically. If you want to understand reality you must look at a problem in multiple dimensions — how could it be otherwise? Getting to this level of understanding requires having a lot of tools and knowing how to use them. You knew there was a hitch right? We need to change our fast-food diet of information consumption and adopt the healthier diet of knowledge that changes slowly over time. While changing diets isn't easy, it can be incredibly rewarding: more time, less stress, and being better at your job. The costs, however, are short term pain for long-term gain. You must change how you think.

- IX. 2nd Order Thinking. One example of a model we can immediately conceptualize and use to improve our ability to make better decisions is something we can borrow from ecology called second-order thinking. The simple way to conceptualize this is to ask yourself "If I do X, what will happen *after* that?". I sum this up using the ecologist Garrett Hardin's simple question: "And then what?" A lot of people forget about higher order effects — second and third-order effects or higher. I've been in a lot of meetings where decisions are made and very few people think to the second level, let alone the third. Rather, what typically happens is called first conclusion bias. The brain shuts down and stops thinking at the first idea that comes to mind that seems to address the problem as you understand it. We don't often realize that our first thoughts are usually not even our own thoughts. They usually belong to someone else. We understand the sound-byte but we haven't done the hard work of real thinking. After we reach the first conclusion, our minds often shut down. We don't seek evidence that would contradict our conclusion. We don't ask ourselves what the likely result of this solution would be — we don't ask ourselves "And then what?" We don't ask what other solutions might be even *more* optimal. For example, consider a hypothetical organization that decides to change their incentive systems. They come up with a costly new system that requires substantial changes to the current system. Only they don't consider (or even understand) the problems that the *new* system is likely to create. It's possible they've created more problems than they've solved — only now there are *different* problems they must put their head down to solve. Optically, they "reorganize their incentive programs," but practically, they've simply expended energy to stay in place. Another, perhaps more complicated,

example is when a salesman comes into a company and offers you a software program he claims will lower your operating costs and increase your profits. He's got all these beautiful charts on how much more competitive you'll be and how it will improve everything. This is exactly what you need because your compensation is based on increasing profits. You're sold. Then second-order thinking kicks in and you dare to ask how much of those cost savings are going to go to you and how much will eventually end up benefits enjoyed by customers? To a large extent, that depends on the business you're in. However, you can be damn sure the salesman is now knocking on your competitor's door and telling them you just bought their product and if they want to remain competitive they better purchase it too. Eventually, you all have the new software and no one is truly better off. Thus, in the manner of a crowd of people standing on their tip-toes at a parade, all competitors spend the money but none of them win: The salesman wins and the customer wins. We know, thanks to people like Garrett Hardin, Howard Marks, Charlie Munger, Peter Kaufman, and disciplines like ecology, that there are second and third-order effects. This is how the world really works. It just isn't always a comfortable reality. Understanding how the world works isn't easy and it shouldn't be. It's hard work. If it were easy, everyone would do it. And it's not for everyone. Sometimes, if your goal is to maximize utility, you should focus on getting very, very good in a narrow area and becoming an expert, accepting that you will make many mistakes outside of that domain. But for most, it's extremely helpful to understand the forces at play outside of their narrow area of expertise. Because when you think about it, how could reality be anything other than a synthesis of multiple factors? How could it possibly be otherwise?

- X. When our mental models line up with reality, they help us avoid problems. However, they also cause problems when they don't line up with reality as we think something that isn't true.
- XI. We must be open to other perspectives if we truly want to understand the results of our actions. Despite feeling that we've got all the information, if we're on the ship, the fish in the ocean has more he can share. The second flaw is ego. Many of us tend to have too much invested in our opinions of ourselves to see the world's feedback—the feedback we need to update our beliefs about reality. This creates a profound ignorance that keeps us banging our head against the wall over and over again. Our inability to learn from the world because of our ego happens for many reasons, but two are worth mentioning here. First, we're so

afraid about what others will say about us that we fail to put our ideas out there and subject them to criticism. This way we can always be right. Second, if we do put our ideas out there and they are criticized, our ego steps in to protect us. We become invested in defending instead of upgrading our ideas. The third flaw is distance. The further we are from the results of our decisions, the easier it is to keep our current views rather than update them. When you put your hand on a hot stove, you quickly learn the natural consequence. You pay the price for your mistakes. Since you are a pain avoiding creature, you update your view. Before you touch another stove, you check to see if it's hot. But you don't just learn a micro lesson that applies in one situation. Instead, you draw a general abstraction, one that tells you to check before touching anything that could potentially be hot. Organizations over a certain size often remove us from the direct consequences of our decisions. When we make decisions that other people carry out, we are one or more levels removed and may not immediately be able to update our understanding.

Step 205-Use Thinking, Logic, Mental Tools, Thinking Tools.

1. **Go to the Rules of Reading Part 7: Thinking, Logic and Mental Model For Deep Work or Deep Study, Or Bible Study**
2. Listen, Follow and Apply **Thinking, Logic and Mental Model PART 7 Part 7: Thinking, Logic and Mental Model For Deep Work or Deep Study, Or Bible Study**
 1. **Step 57- Slow Down. Pages 1061-1063.**
 2. **Step 58- NOT MULTITASK. Pages 1064.**
 3. **Step 59-You Have Required To Do The Work For Thinking and Applying Mental Tool Models. Pages 1065-1080.**
 4. **Step 60-Why Critical Thinking, Logic, Thinking and Mental Tools Are Important? Pages 1081-1083.**
 5. **Step 61-Intradisciplinary Thinking. Pages 1084-1125.**
 6. **Step 62-Multidisciplinary Thinking. Pages 1126-1168.**
 7. **Step 63-CrossDisciplinary Thinking. Pages 1169-1211.**
 8. **Step 64-Interdisciplinary Thinking. Pages 1212-1254.**
 9. **Step 65-Transdisciplinary Thinking. Pages 1255-1298.**
 10. **Step 66-Journaling. Pages 1299.**
 11. **Step 67-Letting The World Do The Work For You. Pages 1300-1305.**
 12. **Step 68-Journaling. Pages 1306.**
 13. **Step 69-Letting The World Do The Work For You. Pages 1307-1312.**

*Part 32: Pareto Principle, Vital
Few and Trivial Many or 80/20
Principle*

Step 206-80/20 Principle

80/20 Principle or Pareto Principle

General Information About 80/20 Principle

1. Books On The 80/20 Principle:

- I. Eat That Frog.
- II. The 80 20 principle.
- III. 80/20 sales and marketing.
- IV. Pareto's 80 20 Rule for Corporate Accountants.
- V. The 80_20 investor _ investing in an uncertain and complex world -- how to simplify investing with a single principle.

2. DEFINITION OF THE 80/20 PRINCIPLE: The 80/20 Principle states that there is an inbuilt imbalance between causes and results, inputs and outputs, and effort and reward. Typically, causes, inputs, or effort divide into two categories:

- I. The majority, that have little impact. This means 80% inputs will result in 20% outputs
- II. A small minority, that have a major, dominant. This means 20% inputs will result in 80% output.
- III. 80 percent of outputs result from 20 percent of inputs; that 80 percent of consequences flow from 20 percent of causes; or that 80 percent of results come from 20 percent of effort.
- IV. Once you Find Out, what is 20% input that gives 80 of Output. Then You need to Put 100% effort into those 20% inputs, to achieve the best results.

3. The 80/20 Principle asserts that when two sets of data, relating to causes and results, can be examined and analysed, the most likely result is that there will be a pattern of imbalance. The imbalance may be 65/35, 70/30, 75/25, 80/20, 85/15, 90/10, 95/5, or 99.9/0.1, or any set of numbers in between. However, the two numbers in the comparison don't have to add up to 100. Example: Two

economists have just made a study of the revenues and lifespans of 300 movies released over an 18-month period. They found that four movies—just 1.3 percent of the total—earned 80 percent of box office revenues; the other 296 movies or 98.7 percent earned only 20 percent of the gross. So movies, which are a good example of unrestricted markets at work, produce virtually an 80/1 rule, a very clear demonstration of the principle of imbalance.

4. The 80/20 Principle can and should be used by every intelligent person in their every area of daily life, by every organisation, and by every social grouping and form of society. It can help individuals and groups achieve much more, with much less effort.
5. Understanding the 80/20 Principle gives you great insight into what is really happening in the world around you.
6. 80/20 Analysis.
 - I. Traditionally, the 80/20 Principle has required 80/20 Analysis, a quantitative method to establish the precise relationship between causes/input/effort and results/outputs/rewards. This method uses the possible existence of the 80/20 relationship as a hypothesis and then gathers the facts so that the true relationship is revealed. This is an empirical procedure which may lead to any result ranging from 50/50 to 99.9/0.1. If the result does demonstrate a marked imbalance between inputs and outputs (say a 65/35 relationship or an even more unbalanced one), then normally action is taken as a results.
 - Precise
 - Quantitative
 - Requires Investigation
 - Provides Facts
 - Highly Valuable.
 - II. 80/20 Analysis examines the relationship between two sets of comparable data. One set of data is always a universe of people or objects, usually a large number of 100 or more, that can be turned into a percentage. The other set of data relates to some interesting characteristic of the people or

objects that can be measured and also turned into a percentage. For example, we might decide to look at a group of 100 friends, all of whom are at least occasional beer drinkers, and compare how much beer they drank last week.

- III. What makes 80/20 Analysis unique is that the measurement ranks the second set of data in descending order of importance and makes comparisons between percentages in the two sets of data. In our example, then, we will ask all our 100 friends how many glasses of beer they drank last week and array the answers in a table in descending order. Shows the top 20 and bottom 20 from the table. 80/20 Analysis can compare percentages from the two sets of data (the friends and the amount of beer drunk). In this case, we can say that 70 percent of the beer was drunk by just 20 percent of the friends. This would therefore give us a 70/20 relationship. Introduces an 80/20 frequency distribution chart (or 80/20 chart for short) to summarise the data visually.
- IV. Like any simple and effective tool, 80/20 Analysis can also be misunderstood, misapplied, and, instead of being the means to an unusual insight, serve as the justification for conventional thuggery. 80/20 Analysis, applied inappropriately and in a linear way, can also lead the innocent astray—you need constantly to be vigilant against false logic.
- V. Let me illustrate this with an example from my own new profession, the book trade. It is easy to demonstrate that, in most times and places, about 20 percent of book titles comprise about 80 percent of books sold. For those who are steeped in the 80/20 Principle, this is not surprising. It might seem a short hop to the conclusion that bookshops should cut the range of books they stock or, indeed, that they should concentrate largely or exclusively on “bestsellers.” Yet what is interesting is that in most cases, instead of sending profits up, restricting range has sent profits down. This does not invalidate the 80/20 Principle, for two reasons. The key consideration is not the distribution of books sold, but what customers want. If customers go to the trouble of visiting a bookstore, they want to find a reasonable range of books (as opposed to a kiosk or supermarket, where they don’t expect range). Bookstores should concentrate on the 20

percent of customers who account for 80 percent of their profits and find out what those 20 percent of customers want.

VI. The other reason is that what matters even when considering books (as opposed to customers) is not the distribution of sales—the 20 percent of books that represent 80 percent of sales—but the distribution of profits—the 20 percent of titles that generate 80 percent of profits. Very often, these are not the so-called bestsellers, books written by well-known authors. In fact, a study in the United States revealed that “best sellers represent about 5% of total sales.”⁵ The true bestsellers are often those books that never make it into the charts but sell a reliable quantity year in and year out, often at high margins. As the same U.S. research comments, “Core inventory represents those books that sell season-in and season-out. They are the ‘80’ in the 80/20 rule, often accounting for the lion’s share of sales in a particular subject.”

7. 80/20 Thinking.

I. A new and complementary way to use the 80/20 Principle is what I call 80/20 Thinking. This requires deep thought about any issue that is important to you and asks you to make a judgment on whether the 80/20 Principle is working in that area. You can then act on the insight. 80/20 Thinking does not require you to collect data or actually test the hypothesis. Consequently, 80/20 Thinking may on occasion mislead you—it is dangerous to assume, for example, that you already know what the 20 percent is if you identify a relationship—but I will argue that 80/20 Thinking is much less likely to mislead you than is conventional thinking. 80/20 Thinking is much more accessible and faster than 80/20 Analysis, although the latter may be preferred when the issue is extremely important and you find it difficult to be confident about an estimate.

- Fuzzy
- Qualitative
- Requires Deep Thought
- Provides Insight

- **Highly Valuable**

- II. **80/20 Analysis is extremely useful. But most people are not natural analysts, and even analysts cannot stop to investigate the data every time they have to make a decision—it would bring life to a shuddering halt. Most important decisions have never been made by analysis and never will be, however clever our computers become. Therefore, if we want the 80/20 Principle to be a guide in our daily lives, we need something less analytical and more instantly available than 80/20 Analysis. We need 80/20 Thinking.**
- III. **80/20 Thinking is my phrase for the application of the 80/20 Principle to daily life, for nonquantitative applications of the principle. As with 80/20 Analysis, we start with a hypothesis about a possible imbalance between inputs and outputs, but, instead of collecting data and analyzing them, we estimate them. 80/20 Thinking requires, and with practice enables, us to spot the few really important things that are happening and ignore the mass of unimportant things. It teaches us to see the wood for the trees.**
- IV. **80/20 Thinking is too valuable to be confined to causes where data and analysis are perfect. For every ounce of insight generated quantitatively, there must be many pounds of insight arrived at intuitively and impressionistically. This is why 80/20 Thinking, although helped by data, must not be constrained by it**
- V. **To engage in 80/20 Thinking, we must constantly ask ourselves: Vital Few :what is the 20 percent that is leading to 80 percent? Ask Trivial Many : What is 80 percent that leads to 20 percent. We must never assume that we automatically know what the answer is but take some time to think creatively about it. What are the vital few inputs or causes, as opposed to the trivial many? Where is the haunting melody being drowned out by the background noise?**
 - **Once you Find Out, what is 20% input that gives 80 of Output. Then You need to Put 100% effort into those 20% inputs, to achieve the best results. Additionally Remove Trivial Many.**

8. Application of the 80/20 Principle implies that we should do the following:

- I. Celebrate exceptional productivity, rather than raise average efforts**
- II. Look for the short cut, rather than run the full course**
- III. Exercise control over our lives with the least possible effort**
- IV. Be selective, not exhaustive**
- V. Strive for excellence in few things, rather than good performance in many**
- VI. Delegate or outsource as much as possible in our daily lives and be encouraged rather than penalized by tax systems to do this (use gardeners, car mechanics, decorators, and other specialists to the maximum, instead of doing the work ourselves).**
- VII. Choose our careers and employers with extraordinary care, and if possible employ others rather than being employed ourselves**
- VIII. Only do the thing we are best at doing and enjoy most**
- IX. Look beneath the normal texture of life to uncover ironies and oddities**
- X. In every important sphere, work out where 20 percent of effort can lead to 80 percent of returns**
- XI. Calm down, work less and target a limited number of very valuable goals where the 80/20 Principle will work for us, rather than pursuing every available opportunity.**
- XII. Make the most of those few “lucky streaks” in our life where we are at our creative peak and the stars line up to guarantee success.**

9. Low Value use of Time.

- I. 1 Things other people want you to do**
- II. 2 Things that have always been done this way**
- III. 3 Things you're not unusually good at doing**
- IV. 4 Things you don't enjoy doing**
- V. 5 Things that are always interrupted**
- VI. 6 Things few other people are interested in**
- VII. 7 Things that have already taken twice as long as you originally expected.**
- VIII. 8 Things where your collaborators are unreliable or low quality**
- IX. 9 Things that have a predictable cycle**

10. High Value use of Time

- I. 1 Things that advance your overall purpose in life
- II. 2 Things you have always wanted to do
- III. 3 Things already in the 20/80 relationship of time to results
- IV. 4 Innovative ways of doing things that promise to slash the time required and/or multiply the quality of results
- V. 5 Things other people tell you can't be done
- VI. 6 Things other people have done successfully in a different arena
- VII. 7 Things that use your own creativity
- VIII. 8 Things that you can get other people to do for you with relatively little effort on your part
- IX. 9 Anything with high-quality collaborators who have already transcended the 80/20 rule of time, who use time eccentrically and effectively
- X. 10 Things for which it is now or never

11. When thinking about any potential use of time, ask two questions:

- I. Is it unconventional?
- II. Does it promise to multiply effectiveness?

Apply 80/20 Principle In Business

- 1. Large Project- Sales 35,000, Profit 16,000 euro and return on sales is 45%.**
- 2. Small Project Sales 135,000, Profit 12,825 euro, and return on sales is 9.5%.**
- 3. Total: Sales 170,000, profit 28,825 euro and return on sales is 17%.**
- 4. These figures exhibit a 56/21 rule: large projects constitute only 21 percent (35,000/170,000) of turnover but give 56 percent of profits (16,000/28,825).**
- 5. These figures tell us that 26 percent of the business (old clients) made up 84 percent of the profits: an 84/26 rule. The message here was to strive above all to keep and expand long-serving clients, who were the least price sensitive and who could be served most cheaply. New clients who do not turn into long-serving clients were recognised as being loss makers, leading to a much more selective approach to pitching for business: pitches were only made where it was believed the company concerned would turn into a long-term client.**
 - I. Old Clients: Sales 43,500, Profit 24,055 and Return on Sales 55.3%**
 - II. Intermediate Clients Sales 101,000, profit 12,726, return on sales 12.6%**
 - III. New Clients: sales 25,500, profit -7,956, and return on sales 31.2%**
 - IV. Total: Sales 170,000, profit 28,825 and Return on sales 17%**

*Part 33: Classical Books, Liberal
Art and Great Books of Western
World*

Step 207 - Great Books of Western World

Volume 1

- [The Great Conversation](#)

Volume 2

- [Syntopicon I](#): [Angel](#), [Animal](#), [Aristocracy](#), [Art](#), [Astronomy](#), [Beauty](#), [Being](#), [Cause](#), [Chance](#), [Change](#), [Citizen](#), [Constitution](#), [Courage](#), [Custom](#) and [Convention](#), [Definition](#), [Democracy](#), [Desire](#), [Dialectic](#), [Duty](#), [Education](#), [Element](#), [Emotion](#), [Eternity](#), [Evolution](#), [Experience](#), [Family](#), [Fate](#), [Form](#), [God](#), [Good](#) and [Evil](#), [Government](#), [Habit](#), [Happiness](#), [History](#), [Honor](#), [Hypothesis](#), [Idea](#), [Immortality](#), [Induction](#), [Infinity](#), [Judgment](#), [Justice](#), [Knowledge](#), [Labor](#), [Language](#), [Law](#), [Liberty](#), [Life](#) and [Death](#), [Logic](#), and [Love](#)

Volume 3

- [Syntopicon II](#): [Man](#), [Mathematics](#), [Matter](#), [Mechanics](#), [Medicine](#), [Memory](#) and [Imagination](#), [Metaphysics](#), [Mind](#), [Monarchy](#), [Nature](#), [Necessity](#) and [Contingency](#), [Oligarchy](#), [One](#) and [Many](#), [Opinion](#), [Opposition](#), [Philosophy](#), [Physics](#), [Pleasure](#) and [Pain](#), [Poetry](#), [Principle](#), [Progress](#), [Prophecy](#), [Prudence](#), [Punishment](#), [Quality](#), [Quantity](#), [Reasoning](#), [Relation](#), [Religion](#), [Revolution](#), [Rhetoric](#), [Same](#) and [Other](#), [Science](#), [Sense](#), [Sign](#) and [Symbol](#), [Sin](#), [Slavery](#), [Soul](#), [Space](#), [State](#), [Temperance](#), [Theology](#), [Time](#), [Truth](#), [Tyranny](#), [Universal](#) and [Particular](#), [Virtue](#) and [Vice](#), [War](#) and [Peace](#), [Wealth](#), [Will](#), [Wisdom](#), and [World](#)

Volume 4

- Old Testament
- New Testament
- [Homer](#) (rendered into English prose by [Samuel Butler](#))
 - The [Iliad](#)
 - The [Odyssey](#)

Volume 5

- [Aeschylus](#) (translated into English verse by G.M. Cookson)
 - [*The Suppliant Maidens*](#)
 - [*The Persians*](#)
 - [*Seven Against Thebes*](#)
 - [*Prometheus Bound*](#)
 - [*The Oresteia*](#)
 - [*Agamemnon*](#)
 - [*Choephoroe*](#)
 - [*The Eumenides*](#)
- [Sophocles](#) (translated into English prose by Sir Richard C. Jebb)
 - [*The Oedipus Cycle*](#)
 - [*Oedipus the King*](#)
 - [*Oedipus at Colonus*](#)
 - [*Antigone*](#)
 - [*Ajax*](#)
 - [*Electra*](#)
 - [*The Trachiniae*](#)
 - [*Philoctetes*](#)
- [Euripides](#) (translated into English prose by Edward P. Coleridge)
 - [*Rhesus*](#)
 - [*Medea*](#)
 - [*Hippolytus*](#)
 - [*Alcestis*](#)
 - [*Heracleidae*](#)
 - [*The Suppliants*](#)
 - [*The Trojan Women*](#)
 - [*Ion*](#)
 - [*Helen*](#)
 - [*Andromache*](#)
 - [*Electra*](#)
 - [*Bacchantes*](#)
 - [*Hecuba*](#)
 - [*Heracles Mad*](#)
 - [*The Phoenician Women*](#)
 - [*Orestes*](#)
 - [*Iphigenia in Tauris*](#)
 - [*Iphigenia in Aulis*](#)
 - [*Cyclops*](#)

- [Aristophanes](#) (translated into English verse by [Benjamin Bickley Rogers](#))
 - [*The Acharnians*](#)
 - [*The Knights*](#)
 - [*The Clouds*](#)
 - [*The Wasps*](#)
 - [*Peace*](#)
 - [*The Birds*](#)
 - [*The Frogs*](#)
 - [*Lysistrata*](#)
 - [*Thesmophoriazousae*](#)
 - [*Ecclesiazousae*](#)
 - [*Plutus*](#)

Volume 6

- [Herodotus](#)
 - [*The History*](#) (translated by [George Rawlinson](#))
- [Thucydides](#)
 - [*History of the Peloponnesian War*](#) (translated by [Richard Crawley](#) and revised by R. Feetham)

Volume 7

- [Plato](#)

- The Dialogues (translated by [Benjamin Jowett](#))

- [Charmides](#)
 - [Lysis](#)
 - [Laches](#)
 - [Protagoras](#)
 - [Euthydemus](#)
 - [Cratylus](#)
 - [Phaedrus](#)
 - [Ion](#)
 - [Symposium](#)
 - [Meno](#)
 - [Euthyphro](#)
 - [Apology](#)
 - [Crito](#)
 - [Phaedo](#)
 - [Gorgias](#)
 - [The Republic](#)
 - [Timaeus](#)
 - [Critias](#)
 - [Parmenides](#)
 - [Theaetetus](#)
 - [Sophist](#)
 - [Statesman](#)
 - [Philebus](#)
 - [Laws](#)

- [The Seventh Letter](#) (translated by [J. Harward](#))

Volume 8

- [Aristotle](#)
 - [Categories](#)
 - [On Interpretation](#)
 - [Prior Analytics](#)
 - [Posterior Analytics](#)
 - [Topics](#)
 - [Sophistical Refutations](#)
 - [Physics](#)
 - [On the Heavens](#)
 - [On Generation and Corruption](#)
 - [Meteorology](#)
 - [Metaphysics](#)
 - [On the Soul](#)
 - Minor biological works
 - [On Sense and the Sensible](#)
 - [On Memory and Reminiscence](#)
 - [On Sleep and Sleeplessness](#)
 - [On Dreams](#)
 - [On Prophesying by Dreams](#)
 - [On Longevity and Shortness of Life](#)
 - [On Youth and Old Age, On Life and Death, On Breathing](#)

Volume 9

- [Aristotle](#)
 - [History of Animals](#)
 - [Parts of Animals](#)
 - [On the Motion of Animals](#)
 - [On the Gait of Animals](#)
 - [On the Generation of Animals](#)
 - [Nicomachean Ethics](#)
 - [Politics](#)
 - [The Athenian Constitution](#)
 - [Rhetoric](#)
 - [Poetics](#)

Volume 10

- [Hippocrates](#)
 - Works
 - [The Hippocratic Oath](#)
 - [On Ancient Medicine](#)
 - *On Airs, Water, and Places*
 - *The Book of Prognostics*
 - *On Regimen in Acute Diseases*
 - *Of the Epidemics*
 - *On Injuries of the Head*
 - *On the Surgery*
 - *On Fractures*
 - *On the Articulations*
 - *Instruments of Reduction*
 - *Aphorisms*
 - *The Law*
 - *The Ulcer*
 - *On Fistulae*
 - *On Hemorrhoids*
 - [On the Sacred Disease](#)
- [Galen](#)
 - *On the Natural Faculties*

Volume 11

- [Euclid](#)
 - The Thirteen Books of *Euclid's Elements*
- [Archimedes](#)
 - *On the Sphere and Cylinder*
 - *Measurement of a Circle*
 - *On Conoids and Spheroids*
 - *On Spirals*
 - *On the Equilibrium of Planes*
 - *The Sand Reckoner*
 - *The Quadrature of the Parabola*
 - *On Floating Bodies*
 - *Book of Lemmas*
 - *The Method Treating of Mechanical Problems*
- [Apollonius of Perga](#)
 - *On Conic Sections*
- [Nicomachus of Gerasa](#)
 - *Introduction to Arithmetic*

Volume 12

- [Lucretius](#)
 - *On the Nature of Things* (translated by [H.A.J. Munro](#))
- [Epictetus](#)
 - *The Discourses* (translated by [George Long](#))
- [Marcus Aurelius](#)
 - *The Meditations* (translated by [George Long](#))

Volume 13

- [Virgil](#) (translated into English verse by James Rhoades)
 - *Eclogues*
 - *Georgics*
 - *Aeneid*

Volume 14

- [Plutarch](#)
 - *The Lives of the Noble Grecians and Romans* (translated by John Dryden)

Volume 15

- [P. Cornelius Tacitus](#) (translated by [Alfred John Church](#) and William Jackson Brodribb)
 - [The Annals](#)
 - [The Histories](#)

Volume 16

- [Ptolemy](#)
 - [Almagest](#), (translated by [R. Catesby Taliaferro](#))
- [Nicolaus Copernicus](#)
 - [On the Revolutions of Heavenly Spheres](#) (translated by [Charles Glenn Wallis](#))
- [Johannes Kepler](#) (translated by [Charles Glenn Wallis](#))
 - [Epitome of Copernican Astronomy](#) (Books IV–V)
 - [The Harmonies of the World](#) (Book V)

Volume 17

- [Plotinus](#)
 - [The Six Enneads](#) (translated by [Stephen MacKenna](#) and [B. S. Page](#))

Volume 18

- [Augustine of Hippo](#)
 - [The Confessions](#)
 - [The City of God](#)
 - [On Christian Doctrine](#)

Volume 19

- [Thomas Aquinas](#)
 - [Summa Theologica](#) (First part complete, selections from second part, translated by the Fathers of the English Dominican Province and revised by Daniel J. Sullivan)

Volume 20

- [Thomas Aquinas](#)
 - [Summa Theologica](#) (Selections from second and third parts and supplement, translated by the Fathers of the English Dominican Province and revised by [Daniel J. Sullivan](#))
- [John Calvin](#)
 - [Institutes of the Christian Religion](#) (Selections)

Volume 21

- [Dante Alighieri](#)
 - *Divine Comedy* (Translated by [Charles Eliot Norton](#))

Volume 22

- [Geoffrey Chaucer](#)
 - *Troilus and Criseyde*
 - *The Canterbury Tales*

Volume 23

- [Niccolò Machiavelli](#)
 - *The Prince*
- [Thomas Hobbes](#)
 - *Leviathan*
- [Erasmus](#)
 - *The Praise of Folly*

Volume 24

- [François Rabelais](#)
 - *Gargantua and Pantagruel*, but only up to book 4.

Volume 25

- [Michel Eyquem de Montaigne](#)
 - *Essays*

Volume 26

- William Shakespeare
 - *The First Part of King Henry the Sixth*
 - *The Second Part of King Henry the Sixth*
 - *The Third Part of King Henry the Sixth*
 - *The Tragedy of Richard the Third*
 - *The Comedy of Errors*
 - *Titus Andronicus*
 - *The Taming of the Shrew*
 - *The Two Gentlemen of Verona*
 - *Love's Labour's Lost*
 - *Romeo and Juliet*
 - *The Tragedy of King Richard the Second*
 - *A Midsummer Night's Dream*
 - *The Life and Death of King John*
 - *The Merchant of Venice*
 - *The First Part of King Henry the Fourth*
 - *The Second Part of King Henry the Fourth*
 - *Much Ado About Nothing*
 - *The Life of King Henry the Fifth*
 - *Julius Caesar*
 - *As You Like It*

Volume 27

- [William Shakespeare](#)
 - [*Twelfth Night; or, What You Will*](#)
 - [*The Tragedy of Hamlet, Prince of Denmark*](#)
 - [*The Merry Wives of Windsor*](#)
 - [*Troilus and Cressida*](#)
 - [*All's Well That Ends Well*](#)
 - [*Measure for Measure*](#)
 - [*Othello, the Moor of Venice*](#)
 - [*King Lear*](#)
 - [*Macbeth*](#)
 - [*Antony and Cleopatra*](#)
 - [*Coriolanus*](#)
 - [*Timon of Athens*](#)
 - [*Pericles, Prince of Tyre*](#)
 - [*Cymbeline*](#)
 - [*The Winter's Tale*](#)
 - [*The Tempest*](#)
 - [*The Famous History of the Life of King Henry the Eighth*](#)
 - [*Sonnets*](#)

Volume 28

- [William Gilbert](#)
 - [*On the Loadstone and Magnetic Bodies*](#)
- [Galileo Galilei](#)
 - [*Dialogues Concerning the Two New Sciences*](#)
- [William Harvey](#)
 - [*On the Motion of the Heart and Blood in Animals*](#)
 - *On the Circulation of Blood*
 - *On the Generation of Animals*

Volume 29

- [Miguel de Cervantes](#)
 - [The History of Don Quixote de la Mancha](#) (translated by John Ormsby)

Volume 30

- [Sir Francis Bacon](#)
 - [The Advancement of Learning](#)
 - [Novum Organum](#)
 - [New Atlantis](#)

Volume 31

- [René Descartes](#)
 - [Rules for the Direction of the Mind](#)
 - [Discourse on the Method](#)
 - [Meditations on First Philosophy](#)
 - [Objections Against the Meditations and Replies](#)
 - [The Geometry](#)
- [Benedict de Spinoza](#)
 - [Ethics](#)
- [Molière](#)
 - [The School for Wives](#)
 - [The Critique of the School for Wives](#)
 - [Tartuffe](#)
 - [Don Juan](#)
 - [The Miser](#)
 - [The Would-Be Gentleman](#)
 - [The Imaginary Invalid](#)
- [Jean Racine](#)
 - [Bérénice](#)
 - [Phèdre](#)

Volume 32

- [John Milton](#)
 - English Minor Poems
 - [On the Morning of Christ's Nativity](#)
 - A Paraphrase on Psalm 114
 - Psalm 136
 - [The Passion](#)
 - *On Time*
 - [Upon the Circumcision](#)
 - *At a Solemn Musick*
 - *An Epitaph on the Marchioness of Winchester*
 - *Song on May Morning*
 - *On Shakespeare*
 - *On the University Carrier*
 - *Another on the same*
 - [L'Allegro](#)
 - [Il Penseroso](#)
 - [Arcades](#)
 - [Lycida](#)
 - [Comus](#)
 - *On the Death of a Fair Infant*
 - *At a Vacation Exercise*
 - *The Fifth Ode of Horace*
 - Sonnets (I, and VII—XIX)
 - *On the New Forcers of Conscience*
 - *On the Lord General Fairfax at the Siege of Colchester*
 - *To the Lord General Cromwell*
 - *To Sir Henry Vane the Younger*
 - *To Mister Cyriack the Skinner upon his Blindness*
 - Psalms (I—VIII & LXXX—LXXXVIII)
 - [Paradise Lost](#)
 - [Samson Agonistes](#)
 - [Areopagitica](#)

Volume 33

- [Blaise Pascal](#)
 - [The Provincial Letters](#)
 - [Pensées](#)
 - Scientific and mathematical essays

Volume 34

- [Sir Isaac Newton](#)
 - [Mathematical Principles of Natural Philosophy](#)
 - [Optics](#)
- [Christiaan Huygens](#)
 - [Treatise on Light](#)
- [Voltaire](#)
 - [Candide](#)
- [Denis Diderot](#)
 - [Rameau's Nephew](#)

Volume 35

- [John Locke](#)
 - [A Letter Concerning Toleration](#)
 - [Concerning Civil Government, Second Essay](#)
 - [An Essay Concerning Human Understanding](#)
- [George Berkeley](#)
 - [The Principles of Human Knowledge](#)
- [David Hume](#)
 - [An Enquiry Concerning Human Understanding](#)

Volume 36

- [Jonathan Swift](#)
 - [Gulliver's Travels](#)
- [Laurence Sterne](#)
 - [The Life and Opinions of Tristram Shandy, Gentleman](#)

Volume 37

- [Henry Fielding](#)
 - [The History of Tom Jones, a Foundling](#)

Volume 38

- [Charles de Secondat, Baron de Montesquieu](#)
 - [The Spirit of the Laws](#)
- [Jean Jacques Rousseau](#)
 - [A Discourse on the Origin of Inequality](#)
 - [A Discourse on Political Economy](#)
 - [The Social Contract](#)

Volume 39

- [Adam Smith](#)
 - [An Inquiry into the Nature and Causes of the Wealth of Nations](#)

Volume 40

- [Edward Gibbon](#)
 - [The Decline and Fall of the Roman Empire](#) (Part 1)

Volume 41

- [Edward Gibbon](#)
 - [The Decline and Fall of the Roman Empire](#) (Part 2)

Volume 42

- [Immanuel Kant](#)
 - [Critique of Pure Reason](#)
 - [Fundamental Principles of the Metaphysic of Morals](#)
 - [Critique of Practical Reason](#)
 - Excerpts from [The Metaphysics of Morals](#)
 - *Preface and Introduction to the Metaphysical Elements of Ethics with a note on Conscience*
 - *General Introduction to the Metaphysic of Morals*
 - *The Science of Right*
 - [The Critique of Judgement](#)

Volume 43

- American State Papers
 - [Declaration of Independence](#)
 - [Articles of Confederation](#)
 - [The Constitution of the United States of America](#)
- [Alexander Hamilton, James Madison, John Jay](#)
 - [*The Federalist*](#)
- [John Stuart Mill](#)
 - [*On Liberty*](#)
 - [*Considerations on Representative Government*](#)
 - [*Utilitarianism*](#)
- [Søren Kierkegaard](#)
 - [*Fear and Trembling*](#)
- [Friedrich Nietzsche](#)
 - [*Beyond Good and Evil*](#)

Volume 44

- [James Boswell](#)
 - [*The Life of Samuel Johnson, LL.D.*](#)
- [Alexis de Tocqueville](#)
 - [*Democracy in America*](#)

Volume 45

- [Antoine Laurent Lavoisier](#)
 - [*Elements of Chemistry*](#)
- [Jean Baptiste Joseph Fourier](#)
 - *Analytical Theory of Heat*
- [Michael Faraday](#)
 - *Experimental Researches in Electricity*
- [Honoré de Balzac](#)
 - [*Cousin Bette*](#)

Volume 46

- [Georg Wilhelm Friedrich Hegel](#)
 - [*The Philosophy of Right*](#)
 - [*The Philosophy of History*](#)
- [Jane Austen](#)
 - [*Emma*](#)
- [George Eliot](#)
 - [*Middlemarch*](#)

Volume 47

- [Johann Wolfgang von Goethe](#)
 - [*Faust*](#)
- [Charles Dickens](#)
 - [*Little Dorrit*](#)

Volume 48

- [Herman Melville](#)
 - [*Moby Dick; or, The Whale*](#)
- [Mark Twain](#)
 - [*Huckleberry Finn*](#)

Volume 49

- [Charles Darwin](#)
 - [*The Origin of Species by Means of Natural Selection*](#)
 - [*The Descent of Man, and Selection in Relation to Sex*](#)

Volume 50

- [Karl Marx](#)
 - [*Capital*](#)
- [Karl Marx](#) and [Friedrich Engels](#)
 - [*Manifesto of the Communist Party*](#)

Volume 51

- [Count Leo Tolstoy](#)
 - [*War and Peace*](#)

Volume 52

- [Fyodor Mikhailovich Dostoevsky](#)
 - [*The Brothers Karamazov*](#)
- [Henrik Ibsen](#)
 - [*A Doll's House*](#)
 - [*The Wild Duck*](#)
 - [*Hedda Gabler*](#)
 - [*The Master Builder*](#)

The contents of the six volumes of added 20th-century material:

Volume 53

- [William James](#)
 - [*The Principles of Psychology*](#)

Volume 54

- [Sigmund Freud](#)
 - *The Origin and Development of Psycho-Analysis*
 - *Selected Papers on Hysteria*
 - *The Sexual Enlightenment of Children*
 - *The Future Prospects of Psycho-Analytic Therapy*
 - *Observations on "Wild" Psycho-Analysis*
 - [*The Interpretation of Dreams*](#)

 - *The Unconscious*
 - [*A General Introduction to Psycho-Analysis*](#)
 - [*Beyond the Pleasure Principle*](#)
 - [*Group Psychology and the Analysis of the Ego*](#)
 - [*The Ego and the Id*](#)
 - *Inhibitions, Symptoms, and Anxiety*
 - [*Thoughts for the Times on War and Death*](#)
 - [*Civilization and Its Discontents*](#)
 - *New Introductory Lectures on Psycho-Analysis*

Volume 55

- [William James](#)
 - *Pragmatism*
- [Henri Bergson](#)
 - "[An Introduction to Metaphysics](#)"
- [John Dewey](#)
 - [*Experience and Education*](#)
- [Alfred North Whitehead](#)
 - *Science and the Modern World*
- [Bertrand Russell](#)
 - [*The Problems of Philosophy*](#)
- [Martin Heidegger](#)
 - *What Is Metaphysics?*
- [Ludwig Wittgenstein](#)
 - [*Philosophical Investigations*](#)
- [Karl Barth](#)
 - *The Word of God and the Word of Man*

Volume 56

- [Henri Poincaré](#)
 - *Science and Hypothesis*
- [Max Planck](#)
 - *Scientific Autobiography and Other Papers*
- [Alfred North Whitehead](#)
 - *An Introduction to Mathematics*
- [Albert Einstein](#)
 - *Relativity: The Special and the General Theory*
- [Arthur Eddington](#)
 - *The Expanding Universe*
- [Niels Bohr](#)
 - *Atomic Theory and the Description of Nature* (selections)
 - *Discussion with Einstein on Epistemology*
- [G. H. Hardy](#)
 - [*A Mathematician's Apology*](#)
- [Werner Heisenberg](#)
 - *Physics and Philosophy*
- [Erwin Schrödinger](#)
 - [*What Is Life?*](#)
- [Theodosius Dobzhansky](#)
 - [*Genetics and the Origin of Species*](#)
- [C. H. Waddington](#)
 - *The Nature of Life*

Volume 57

- [Thorstein Veblen](#)
 - [*The Theory of the Leisure Class*](#)
- [R. H. Tawney](#)
 - *The Acquisitive Society*
- [John Maynard Keynes](#)
 - [*The General Theory of Employment, Interest and Money*](#)

Volume 58

- [Sir James George Frazer](#)
 - [The Golden Bough](#) (selections)
- [Max Weber](#)
 - [Essays in Sociology](#) (selections)
- [Johan Huizinga](#)
 - [The Autumn of the Middle Ages](#)
- [Claude Lévi-Strauss](#)
 - [Structural Anthropology](#) (selections)

Volume 59

- [Henry James](#)
 - [The Beast in the Jungle](#)
- [George Bernard Shaw](#)
 - [Saint Joan](#)
- [Joseph Conrad](#)
 - [Heart of Darkness](#)
- [Anton Chekhov](#)
 - [Uncle Vanya](#)
- [Luigi Pirandello](#)
 - [Six Characters in Search of an Author](#)
- [Marcel Proust](#)
 - [Remembrance of Things Past](#): "Swann in Love"
- [Willa Cather](#)
 - [A Lost Lady](#)
- [Thomas Mann](#)
 - [Death in Venice](#)
- [James Joyce](#)
 - [A Portrait of the Artist as a Young Man](#)

Volume 60

- [Virginia Woolf](#)
 - [*To the Lighthouse*](#)
- [Franz Kafka](#)
 - [*The Metamorphosis*](#)
- [D. H. Lawrence](#)
 - [*The Prussian Officer*](#)
- [T. S. Eliot](#)
 - [*The Waste Land*](#)
- [Eugene O'Neill](#)
 - [*Mourning Becomes Electra*](#)
- [F. Scott Fitzgerald](#)
 - [*The Great Gatsby*](#)
- [William Faulkner](#)
 - [*A Rose for Emily*](#)
- [Bertolt Brecht](#)
 - [*Mother Courage and Her Children*](#)
- [Ernest Hemingway](#)
 - [*The Short Happy Life of Francis Macomber*](#)
- [George Orwell](#)
 - [*Animal Farm*](#)
- [Samuel Beckett](#)
 - [*Waiting for Godot*](#)

Step 208 - Classical Books

Classic Biographies:

Read the personal biographies and autobiographies of the most influential thinkers and inventors in history.

1. [Autobiography of a Yogi](#) (Paramahansa Yogananda)
2. [The World As I See It](#) (Albert Einstein)
3. [My Inventions: The Autobiography Of Nikola Tesla](#) (Nikola Tesla)
4. [The Autobiography of Charles Darwin](#) (Charles Darwin)
6. [The Autobiography of Benjamin Franklin](#) (Benjamin Franklin)
7. [Autobiography: Truth and Fiction Relating to My Life](#) (Johann Wolfgang von Goethe)
8. [The Seven Pillars of Wisdom](#) (T.E. Lawrence)
9. [The Everyday Life of Abraham Lincoln](#) (Francis F. Browne)
10. [Theodore Roosevelt: An Autobiography](#) (Theodore Roosevelt)
11. [The Autobiography of Malcolm X](#) (As Told To Alex Haley)
12. [Mark Twain: A Biography](#) (Albert Bigelow Paine)
13. [The Autobiography of Andrew Carnegie](#) (Andrew Carnegie)
14. [The Story of My Life](#) (Helen Keller)

Philosophy:

Deepen your knowledge of philosophy with the classics of Western Philosophy.

1. [The Republic](#) (Plato)
2. [Thus Spake Zarathustra](#) (Friedrich Nietzsche)
3. [Beyond Good and Evil](#) (Friedrich Nietzsche)
4. [The Critique of Pure Reason](#) (Immanuel Kant)
5. [The Problems of Philosophy](#) (Bertrand Russell)
6. [History of Western Philosophy](#) (Bertrand Russell)
7. [A Pluralistic Universe](#) (William James)
8. [The Nicomachean Ethics](#) (Aristotle)
9. [Meditations](#) (Marcus Aurelius)
10. [A Treatise of Human Nature](#) (David Hume)
11. [Mere Christianity](#) (C.S. Lewis)
12. [The Wisdom of Life](#) (Arthur Schopenhauer)
13. [Utopia](#) (Thomas More)
14. [Island](#) (Aldous Huxley)

Politics:

Influential political treatises that ignited modern political debates that still rage.

1. [The Wealth of Nations](#) (Adam Smith)
2. [The Age of Reason](#) (Thomas Paine)
3. [Common Sense](#) (Thomas Paine)
4. [The Prince](#) (Niccolò Machiavelli)
5. [Second Treatise of Government](#) (John Locke)
6. [The Communist Manifesto](#) (Friedrich Engels and Karl Marx)
7. [On Liberty](#) (John Stuart Mill)
8. [Proposed Roads to Freedom](#) (Bertrand Russell)
9. [Anarchism and Other Essays](#) (Emma Goldman)
10. [Democracy in America](#) (Alexis de Tocqueville)
11. [Brave New World](#) (Aldous Huxley)
12. [1984](#) (George Orwell)

Education:

Thought-provoking books on the nature of education and how to deepen your understanding of life.

1. [Education and the Significance of Life](#) (Jiddhu Krishnamurti)
2. [Dr. Montessori's Own Handbook](#) (Maria Montessori)
3. [The Montessori Method](#) (Maria Montessori)
4. [Democracy and Education](#) (John Dewey)
5. [Deschooling Society](#) (Ivan Illich)
6. [Weapons of Mass Instruction](#) (John Taylor Gatto)

Psychology:

Explore the inner workings of the human mind through the lens of modern psychology.

1. [Dream Psychology](#) (Sigmund Freud)
2. [The Psychology of Revolution](#) (Gustav Le Bon)
3. [Your Mind and How to Use It: A Manual of Practical Psychology](#) (Walter Atkinson)
4. [The Mass Psychology of Fascism](#) (Wilhelm Reich)
5. [Dreams](#) (Henry Bergson)
6. [As a Man Thinketh](#) (James Allen)
7. [The Varieties of Religious Experience: A Study in Human Nature](#) (William James)

Science:

1. [The Mathematical Principles of Natural Philosophy](#) (Sir Isaac Newton)
2. [On the Origin of Species](#) (Charles Darwin)
3. [Physics](#) (Aristotle)
4. [The Pioneers of Science](#) (Sir Oliver Lodge)
5. [Relativity: The Special & the General Theory](#) (Albert Einstein)
6. [The Journals of Lewis and Clark](#) (William Clark and Meriwether Lewis)

Western Religion:

The three Abrahamic religions and their different cultural translations of God, scripture and truth.

1. [The Torah](#)
2. [The Bible](#)
3. [The Koran](#)

Eastern Religion:

The Eastern religious traditions and their radically different ideas of liberation and the nature of being.

1. [The Yoga Sutras of Patanjali](#)
2. [The Rig Veda](#)
3. [The Upanishads](#)
4. [The Mahabharata](#)
5. [The Ramayan](#)
6. [The Bhagavad Gita](#)
7. [The Kama Sutra of Vatsyayana](#)
8. [The Dhammapada: The Sayings of The Buddha](#)
9. [The Tao Te Ching](#)

English/Scottish/Irish/Welsh Classics:

Literary classics from the nations that comprise the United Kingdom.

1. [The Life and Adventures of Robinson Crusoe](#) (Daniel Defoe)
2. [The Adventures of Sherlock Holmes](#) (Arthur Conan Doyle)
3. [The Lost World](#) (Arthur Conan Doyle)
4. [Ulysses](#) (James Joyce)
5. [A Portrait of the Artist as a Young Man](#) (James Joyce)
6. [Finnegan's Wake](#) (James Joyce)
7. [Treasure Island](#) (Robert Louis Stevenson)
8. [A Tale of Two Cities](#) (Charles Dickens)
9. [Great Expectations](#) (Charles Dickens)
10. [Pride and Prejudice](#) (Jane Austen)
11. [The Picture of Dorian Gray](#) (Oscar Wilde)
12. [The Importance of Being Earnest](#) (Oscar Wilde)
13. [Gulliver's Travels](#) (Jonathan Swift)
14. [A Modest Proposal](#) (Jonathan Swift)
15. [The Jungle Book](#) (Rudyard Kipling)
16. [Dracula](#) (Bram Stoker)
17. [The Time Machine](#) (H. G. Wells)
18. [The Complete Works](#) (William Shakespeare)
19. [Paradise Lost](#) (John Milton)

20. [The Canterbury Tales](#) (Geoffrey Chaucer)
21. [Heart of Darkness](#) (Joseph Conrad)
22. [The Lord Of The Rings](#) (J. R. R. Tolkien)
23. [Alice's Adventures in Wonderland](#) (Lewis Carroll)
24. [Through the Looking-Glass](#) (Lewis Carroll)
25. [The Pilgrim's Progress](#) (John Bunyan)
26. [The Chronicles of Narnia](#) (C.S. Lewis)

Western European Classics:

Literary classics from the Western European nations of Germany, France, Spain, and Italy.

1. [Siddhartha](#) (Hermann Hesse)
2. [The Count of Monte Cristo](#) (Alexandre Dumas)
3. [Grimms' Fairy Tales](#) (Jacob Grimm and Wilhelm Grimm)
4. [Les Misérables](#) (Victor Hugo)
5. [The Divine Comedy](#) (Dante)
6. [Candide](#) (Voltaire)
7. [Don Quixote](#) (Miguel de Cervantes Saavedra)
8. [Around the World in Eighty Days](#) (Jules Verne)
9. [Faust](#) (Johann Wolfgang von Goethe)
10. [The Notebooks of Leonardo Da Vinci](#) (Leonardo da Vinci)
11. [Madame Bovary](#) (Gustave Flaubert)

12. [The Stranger](#) (Albert Camus)

American Classics:

American literature classics that have shaped uniquely American ideals of freedom and liberty.

1. [Walden, and On The Duty Of Civil Disobedience](#) (Henry David Thoreau)
2. [Moby Dick](#) (Herman Melville)
3. [Adventures of Huckleberry Finn](#) (Mark Twain)
4. [Leaves of Grass](#) (Walt Whitman)
5. [The Wonderful Wizard of Oz](#) (L. Frank Baum)
6. [The Call of the Wild](#) (Jack London)
7. [Twelve Years a Slave](#) (Solomon Northup)
8. [This Side of Paradise](#) (F. Scott Fitzgerald)
9. [Poems](#) (T. S. Eliot)
10. [Essays](#) (Ralph Waldo Emerson)
11. [On The Road](#) (Jack Kerouac)

Russian Classics:

Renowned Russian literary classics.

1. [War and Peace](#) (Leo Tolstoy)
2. [Anna Karenina](#) (Leo Tolstoy)
3. [The Gulag Archipelago](#) (Aleksandr Solzhenitsyn)
4. [The Brothers Karamazov](#) (Fyodor Dostoyevsky)
5. [Notes from the Underground](#) (Fyodor Dostoyevsky)

Ancient Greek and Roman Literature:

Classic epics from ancient Greece and Rome.

1. [The Iliad](#) (Homer)
2. [The Odyssey](#) (Homer)
3. [Aesop's Fables](#) (Aesop)
4. [Myths and Legends of Ancient Greece and Rome](#) (E. M. Berens)
5. [The History Of The Decline And Fall Of The Roman Empire](#) (Edward Gibbon)

Indian Classics:

Some of the classic books of India.

1. [Sadhana: The Realisation of Life](#) (Rabindranath Tagore)
2. [Gitanjali](#) (Rabindranath Tagore)

Chinese Classics:

Some of the classic books of China.

1. [The Analects](#) (Confucius)
2. [The Sayings of Confucius](#) (Confucius)
3. [Chuang Tzu: Mystic, Moralist, and Social Reformer](#) (Zhuangzi)
4. [The Art of War](#) (Sun Tzu)

Step 209-How To Get Liberal Arts Education without Degree.

While the Classical Liberal Arts typically fall at the bottom of the education hierarchy today, I think it's one of the most valuable education curriculums you can follow to prepare yourself for an uncertain future.

Why? Because nobody can predict which technical or job skills will stay in-demand in a future that will be dominated by robots and artificial intelligence. But studying emerging trends, we do know that we will need to train the uniquely human qualities that can't be replicated by machines.

These uniquely human qualities are what make us effective leaders and good communicators: creativity, empathy, social intelligence, curiosity, storytelling and adaptability.

The Liberal Arts has a bad reputation because it has the lowest barriers to entry of University degrees and it often attracts students that can't get into the more competitive disciplines in Science, Technology, Engineering and Mathematics (STEM). In these technical disciplines, you will fall behind very quickly if you don't diligently focus for long periods of time and complete the daily work assignments.

However, if you really dedicate yourself to studying the Classical Liberal Arts it can be one of the most challenging and helpful University degrees. There are few forms of higher education more effective at building individuals with strong character who are well-rounded and flexible in the face of disruptive change.

And now thanks to the Internet, you don't necessary have to go up to a 100K in debt to get a Liberal Arts education. For a fraction of the cost of a University degree, you create your own own Liberal Arts education while traveling the world and directly experiencing the fascinating cultures, history and museums across the cultural mosaic of human civilization.

What Is The Meaning of Liberalism?

A Classical Liberal Arts education studying the Trivium and Quadrivium while reading the classical and modern work of literature and philosophy that form the generally agreed upon Liberal Arts canon in Western education.

Another important component is regularly debating the most important issues of our day and the human condition with other intelligent and informed people who can challenge you to see your own [cognitive biases](#) and [reality tunnels](#).

While the classical meaning of liberalism is often bastardized by pundits in the media, a liberal is a someone who works to freed himself or herself from the bigotry, authoritarian attitudes and established dogmas.

Liberalism often gets a bad name because of the elitism attached to attaining a Liberal Arts education at a prestigious University. Many highly educated people perpetuate this elitism through their often thinly-veiled contempt for people of lower educational attainment and lesser financial means.

This is misguided. **A real liberal is someone who seeks the freedom and equality of all people** — everywhere in the world — and does not allow him or herself to be caged by any institutional, ideological or class biases.

The 4-Year Liberal Arts Reading List

This 4-Year Liberal Arts reading list is a guide to many of history's most important books at least from a Western perspective (please feel free to share a similar canon from other cultures that has been translated into English in the comments).

If you read the books on this 4-year Liberal Arts reading list you can learn directly from the thinking patterns of history's greatest thinkers and I can guarantee it will transform your world and make you a better person.

This reading list has been reviewed yearly since 1937 by the Liberal Arts faculty at St. John's College to create a generally agreed upon Liberal Arts curriculum that anyone can study in their own time.

The first two years span over 2,000 years of intellectual history and the last two years are from the last 300 years that have seen the development of the ideas that underpin the science and freedom we enjoy in the modern world.

The Liberal Arts reading list is organized in chronological order but you don't necessary need to read these books in any particular order.

If you're really determined, you can complete the entire Liberal Arts canon in about 4 years by reading a book every 1-2 weeks (some larger books will take longer to read though)

However, for most people this education may stretch on for decades as you read the books on the list that most interest you (and I've also created a [21st Century Reading List](#) of other books I recommend reading as well).

1st Year: Greek Civilization and the Classical Liberal Arts

The foundation of Western Civilization was laid by the Greeks. Pythagorus, Socrates, Plato and Aristotle created a liberal renaissance in the ancient European world.

The [Socratic Method](#) and [The Trivium](#) still form of the foundation of one the best systems ever created for critical thinking and rational debate.

1. HOMER: *Iliad, Odyssey*
2. AESCHYLUS: *Agamemnon, Libation Bearers, Eumenides, Prometheus Bound*
3. SOPHOCLES: *Oedipus Rex, Oedipus at Colonus, Antigone, Philoctetes, Ajax*
4. THUCYDIDES: *Peloponnesian War*
5. EURIPIDES: *Hippolytus, Bacchae*
6. HERODOTUS: *Histories*
7. ARISTOPHANES: *Clouds*
8. PLATO (SOCRATES): *Meno, Gorgias, Republic, Apology, Crito, Phaedo, Symposium, Parmenides, Theaetetus, Sophist, Timaeus, Phaedrus*
9. ARISTOTLE: *Poetics, Physics, Metaphysics, Nicomachean Ethics, On Generation and Corruption, Politics, Parts of Animals, Generation of Animals*
10. EUCLID: *Elements*
11. LUCRETIUS: *On the Nature of Things*
12. PLUTARCH: *Lycurgus, Solon*
13. NICOMACHUS: *Arithmetic*
14. LAVOISIER: *Elements of Chemistry*
15. HARVEY: *Motion of the Heart and Blood*
16. Essays by: Archimedes, Fahrenheit, Avogadro, Dalton, Cannizzaro, Virchow, Mariotte, Driesch, Gay-Lussac, Spemann, Stears, J.J. Thompson, Mendeleyev, Berthollet, J.L. Proust.

2nd Year: Roman, Medieval and Renaissance Periods

The Roman Empire lasted nearly 700 years before collapsing under the weight of its immorality and greed.

The period known as the Dark Ages followed, which was characterized by illiteracy and the authoritarian rule of the Catholic Church until the Italian Renaissance and birth of modern world.

1. THE HEBREW BIBLE
2. THE BIBLE: New Testament
3. ARISTOTLE: *De Anima, On Interpretation, Prior Analytics, Categories*
4. APOLLONIUS: *Conics*
5. VIRGIL: *Aeneid*
6. PLUTARCH: "Caesar," "Cato the Younger," "Antony," "Brutus"
7. EPICTETUS: *Discourses, Manual*
8. TACITUS: *Annals*
9. PTOLEMY: *Almagest*
10. PLOTINUS: *The Enneads*
11. AUGUSTINE: *Confessions*
12. MAIMONIDES: *Guide for the Perplexed*
13. ST. ANSELM: *Proslogium*
14. AQUINAS: *Summa Theologica*
15. DANTE: *Divine Comedy*
16. CHAUCER: *Canterbury Tales*
17. MACHIAVELLI: *The Prince, Discourses*
18. KEPLER: *Epitome IV*
19. RABELAIS: *Gargantua and Pantagruel*
20. PALESTRINA: *Missa Papae Marcelli*
21. MONTAIGNE: *Essays*
22. VIETE: *Introduction to the Analytical Art*
23. BACON: *Novum Organum*
24. SHAKESPEARE: *Richard II, Henry IV, The Tempest, As You Like It, Hamlet, Othello, Macbeth, King Lear, and Sonnets*
25. POEMS BY: Marvell, Donne, and other 16th- and 17th-century poets
26. DESCARTES: *Geometry, Discourse on Method*
27. PASCAL: *Generation of Conic Sections*
28. BACH: *St. Matthew Passion, Inventions*
29. HAYDN: *Quartets*
30. MOZART: *Operas*
31. BEETHOVEN: *Third Symphony*
32. SCHUBERT: *Songs*
33. MONTEVERDI: *L'Orfeo*
34. STRAVINSKY: *Symphony of Psalms.*

3rd Year: The Enlightenment in the 17th and 18th Centuries

The separation of the church and state led to the Enlightenment and a new golden age of scholarship and innovation for the modern nations who freed themselves from religious theocracy.

It also led to the despiritualization of the Universe and the dehumanization of people who resisted the evangelical zeal of Western science and religion.

1. CERVANTES: *Don Quixote*
2. GALILEO: *Two New Sciences*
3. HOBBS: *Leviathan*
4. DESCARTES: *Meditations, Rules for the Direction of the Mind*
5. MILTON: *Paradise Lost*
6. LA ROCHEFOUCAULD: *Maximes*
7. LA FONTAINE: *Fables*
8. PASCAL: *Pensees*
9. HUYGENS: *Treatise on Light, On the Movement of Bodies by Impact*
10. ELIOT: *Middlemarch*
11. SPINOZA: *Theological-Political Treatise*
12. LOCKE: *Second Treatise of Government*
13. RACINE: *Phaedre*
14. NEWTON: *Principia Mathematica*
15. KEPLER: *Epitome IV*
16. LEIBNIZ: *Monadology, Discourse on Metaphysics, Essay On Dynamics, Philosophical Essays, Principles of Nature and Grace*
17. SWIFT: *Gulliver's Travels*
18. HUME: *Treatise of Human Nature*
19. ROUSSEAU: *Social Contract, The Origin of Inequality*
20. MOLIÈRE: *Le Misanthrope*
21. ADAM SMITH: *Wealth of Nations*
22. KANT: *Critique of Pure Reason, Foundations of the Metaphysics of Morals*
23. MOZART: *Don Giovanni*
24. JANE AUSTEN: *Pride and Prejudice*
25. DEDEKIND: "Essay on the Theory of Numbers"
26. "Articles of Confederation," "Declaration of Independence," "Constitution of the United States of America"
27. HAMILTON, JAY AND MADISON: *The Federalist*
28. TWAIN: *The Adventures of Huckleberry Finn*
29. WORDSWORTH: *The Two Part Prelude of 1799*
30. Essays by: Young, Taylor, Euler, D. Bernoulli, Orsted, Ampere, Faraday, Maxwell.

4th Year: The Modern World In The 19th and 20th Centuries

The liberal ideals, laws and sciences provided the foundation for the modern world and many of the ideas and philosophies today come from much deeper roots.

These books can help you develop a better understanding the freedoms and flaws of the modern world.

1. Supreme Court opinions
2. GOETHE: *Faust*
3. DARWIN: *Origin of Species*
4. HEGEL: *Phenomenology of Mind*, "Logic" (from the Encyclopedia)
5. LOBACHEVSKY: *Theory of Parallels*
6. TOCQUEVILLE: *Democracy in America*
7. LINCOLN: Selected Speeches
8. FREDERICK DOUGLASS: Selected Speeches
9. KIERKEGAARD: *Philosophical Fragments, Fear and Trembling*
10. WAGNER: *Tristan and Isolde*
11. MARX: *Capital, Political and Economic Manuscripts of 1844, The German Ideology*
12. DOSTOEVSKI: *Brothers Karamazov*
13. TOLSTOY: *War and Peace*
14. MELVILLE: *Benito Cereno*
15. O'CONNOR: Selected Stories
16. WILLIAM JAMES; *Psychology, Briefer Course*
17. NIETZSCHE: *Beyond Good and Evil*
18. FREUD: Introductory Lectures on Psychoanalysis
19. BOOKER T. WASHINGTON: Selected Writings
20. DUBOIS: *The Souls of Black Folk*
21. HUSSERL: *Crisis of the European Sciences*
22. HEIDEGGER: *Basic Writings*
23. EINSTEIN: Selected papers
24. CONRAD: *Heart of Darkness*
25. FAULKNER: *Go Down Moses*
26. FLAUBERT: *Un Coeur Simple*
27. WOOLF: *Mrs. Dalloway*
28. Poems by: Yeats, T.S. Eliot, Wallace Stevens, Valery, Rimbaud
29. Essays by: Faraday, J.J. Thomson, Millikan, Minkowski, Rutherford, Davisson, Schrodinger, Bohr, Maxwell, de Broglie, Heisenberg, Mendel, Boveri, Sutton, Morgan, Beadle & Tatum, Sussman, Watson & Crick, Jacob & Monod, Hardy

Part 34: Motivation Quotes

Step 220-Motivation Quotes

Hard Work

- "I have nothing in common with lazy people who blame others for their lack of success. Great things come from hard work and perseverance. No excuses." Kobe Bryant
- "Do. The Work. Every day, you have to do something you don't want to do. Every day. Challenge yourself to be uncomfortable, push past the apathy and laziness and fear." Tim Grover
- "There are no shortcuts. I don't want to hear about workouts you can do in five minutes a day, or twenty minutes a week; that's total bullshit."
- "I love the guys who want results so much they'll fight me to do more than they're supposed to."
- You keep pushing yourself harder when everyone else has had enough."
- "You get into the Zone, you shut out everything else, and control the uncontrollable."
- "You don't compete with anyone, you find your opponent's weakness and you attack."
- Hard work is everyday process trying to figure out strengths and weaknesses. Then study more to see the places to improve. by Kobe Bryant

Improvement

- *If You Keep Out improving the guys Consistently, eventually, then none of the guys can compete with you* *Patrick Bet Davis.
- “You have power over your mind – not outside events. Realise this, and you will find strength.” Marcus Aurelius
- “If it is not right do not do it; if it is not true do not say it.” Marcus Aurelius
- Everything You do try to learn , how to become better in the craft. When, you have this point of view, then literally the world becomes your library to help you to become better at your craft. Because you know what you want, the world giving you exactly the information you needed. Kobe Bryant
- You have to look at the reality of situation. You need to get over yourself, it is not about you. Like Ok, you feel embarrassed, you are not that important, you worry how people may perceive you and like you are walking around and it's embarrassing because you failed something in front of the crowd. Get over yourself. After that, the. You need ask questions, why did I failed in those situation, got an answer and work on those things hard.
- "The most important conversations you'll ever have are the ones you'll have with yourself."
- The ticket to victory often comes down to bringing your very best when you feel your worst."
- Are you an experienced scuba diver? Great, shed your gear, take a deep breath and become a one-hundred-foot free diver. Are you a badass triathlete? Cool, learn how to rock climb. Are you enjoying a wildly successful career? Wonderful, learn a new language or skill. Get a second degree. Always be willing to embrace ignorance and become the dumb fuck in the classroom again, because that is the only way to expand your body of knowledge and body of work. It's the only way to expand your mind."
- Always be ready to adjust, recalibrate, and stay after it to become better, somehow."

- If you want to master the mind and remove your governor, you'll have to become addicted to hard work. Because passion and obsession, even talent, are only useful tools if you have the work ethic to back them up."
- Most of us sweep our failures and evil secrets under the rug, but when we run into problems, that rug gets lifted up, and our darkness re-emerges, floods our soul, and influences the decisions which determine our character."
- "A lot of us surround ourselves with people who speak to our desire for comfort. People who would rather treat the pain of our wounds and prevent further injury than help us callous over them and try again. We need to surround ourselves with people who will tell us what we need to hear, not what we want to hear, but at the same time not make us feel we're up against the impossible."
- "In every failure there is something to be gained, even if it's only practice for the next test you'll have to take. Because that next test is coming. That's a guarantee."
- There is no more time to waste. Hours and days evaporate like creeks in the desert. That's why it's okay to be cruel to yourself as long as you realize you're doing it to become better."
- Motivation is Crap. Motivation Come and Goes. People right Now maybe listening to this shit, they get motivated go run if its cold somewhere where they are at, a lot of the people shut that door go back inside, that's motivation. It comes and goes as how you feel if you and your wife are good, if you and your kids are good, if you are good at work. I like people whose life is imploded Ain't got shit in life and says, still get after today man. And that's what it's about so that's when you move from motivated to driven to obsessed. And I want people realise that once you get to this portion over here. The driven obsessed part, you are unstoppable. This has to be something that's comes from deep down inside.
- Goggins' approach to motivation is to be aggressively bad-ass towards yourself. Find the things you hate and force yourself to do them again and again until you are numb to the suffering. And then do more. Always do more than the next guy.
- "I never felt that I was good enough, strong enough, smart enough. He let me know that there was always room for improvement. A lot of sons would have been crippled by his demands, but instead the discipline rubbed off on me. I turned it into drive." – Arnold Schwarzenegger

Failure and Success

- *I've missed more than 9,000 shots in my career. I've lost almost 300 games. Twenty-six times I've been trusted to take the game-winning shot and missed. I've failed over and over and over again in my life. And that is why I succeed.* By Michael Jordan.
- I can Accept Failure, everyone fails at something. But I cannot Accept not trying.
By Michael Jordan
- "Just like in bodybuilding, failure is also a necessary experience for growth in our own lives, for if we're never tested to our limits, how will we know how strong we really are? How will we ever grow?" – Arnold Schwarzenegger
- "The last three or four reps is what makes the muscle grow. This area of pain divides the champion from someone else who is not a champion. That's what most people lack, having the guts to go on and just say they'll go through the pain no matter what happens." – Arnold Schwarzenegger
- "Failure is not an option. Everyone has to succeed." – Arnold Schwarzenegger
- "Life's six rules for success. 1. Trust yourself. 2. Break some rules. 3. Don't be afraid to fail. 4. Ignore the naysayers. 5. Work like hell. 6. Give something back." – Arnold Schwarzenegger
- One of the most fascinating lessons I've absorbed about life is that the struggle is good.

Relentless

- "It's a lot more than mind over matter. It takes relentless self-discipline to schedule suffering into your day, every day."

Hardship and Obstacles

- "Obstacles don't have to stop you. If you run into a wall, don't turn around and give up. Figure out how to climb it, go through it, or work around it." By Michael Jordan
- "Don't stop when you're tired. Stop when you're done." "Everyone fails sometimes and life isn't supposed to be fair, much less bend to your every whim." "You must recognize what you are about to do, highlight what you do not like about it, and spend time visualizing each and every obstacle you can. By David Goggins

Weakness and Strengths

- My attitude is that if you push me towards something that you think is a weakness, then I will turn that perceived weakness into a strength." By Michael Jordan
- "Whenever you are about to find fault with someone, ask yourself the following question: What fault of mine most nearly resembles the one I am about to criticize?" Marcus Aurelius.
- "Strength does not come from winning. Your struggles develop your strengths. When you go through hardships and decide not to surrender, that is strength." – Arnold Schwarzenegger
- "If you don't find the time, if you don't do the work, you don't get the results." – Arnold Schwarzenegger
- "Denial is the ultimate comfort zone." ~ David Goggins
- "Life is one big tug of war between mediocrity and trying to find your best self." ~ David Goggins
- "The path to success will leave you callused, bruised, and very tired. It will also leave you empowered." ~ David Goggins
- "Everybody comes to a point in their life when they want to quit. But it's what you do at that moment that determines who you are." ~ David Goggins
- "We don't rise to the level of our expectations, we fall to the level of our training." ~ David Goggins
- "Before you start a goal – let's take care of our insecurities because they are going to surface when you put yourself in the crucible and you're suffering." ~ David Goggins

- “It’s a lot more than mind over matter. It takes relentless self discipline to schedule suffering into your day, every day.” ~ David Goggins
- Analyze your schedule, kill your empty habits, burn out the bullshit, and see what’s left.” ~ David Goggins
- “In every failure a lot of good things will have happened, and we must acknowledge them.” ~ David Goggins
- “A warrior is not a person that carries a gun. The biggest war you ever go through is right between your own ears. It’s in your mind. We’re all going through a war in our mind, and we have to callus our mind to fight that war and to win that war.” ~ David Goggins
- “Refused to compromise who I was to conform to their unwritten rules.” ~ David Goggins
- “Your entitled mind is dead weight. Cut it loose. Don’t focus on what you think you deserve. Take aim on what you are willing to earn!” ~ David Goggins
- “Tell yourself the truth! That you’ve wasted enough time, and that you have other dreams that will take courage to realize...” ~ David Goggins
- “Pain unlocks a secret doorway in the mind, one that leads to both peak performance, and beautiful silence.” ~ David Goggins
- “Suffering is the true test of life.” ~ David Goggins
- “When you’re in hell, you forget how great you really are because you’re suffering and you forget the great things you’ve done.” ~ David Goggins
- “If you want to get better, do the things that no-one else wants to do. Do the things that no-one is even thinking about doing.” ~ David Goggins
- “There is no more time to waste. Hours and days evaporate like creeks in the desert. That’s why it’s okay to be cruel to yourself as long as you realize you’re doing it to become better.” ~ David Goggins
- “Everyone fails sometimes and life isn’t supposed to be fair, much less bend to your every whim.” ~ David Goggins
- “You must recognize what you are about to do, highlight what you do not like about it, and spend time visualizing each and every obstacle you can.” ~ David Goggins
- Everybody wants a quick fix. You may get results, but they won’t be permanent. The permanent results come from you having to suffer.” ~ David Goggins

Gratitude

- “When you arise in the morning think of what a privilege it is to be alive, to think, to enjoy, to love...” Marcus Aurelius

Part 35: Mental Toughness

Step 211-All of David Goggins' Mental Shifts to Reach Full Potential

1. Book By David Goggins

I. Cant Hurt Me_ Master Your Mind and Defy the Odds By David Goggins.

2. Accountability Mirror

The Accountability Mirror is a mirror on which you write what your current situation is, how to get out of it, and what your goals are.

The beauty of the AM is that it doesn't lie.

It shows you *exactly* who you are, stripping the truth from every embellishing story you tell yourself.

David used the AM at the very beginning to assess his situation and plan his next step.

3. Taking Souls

Taking souls is a practice aimed at silencing whoever is doubting you.

The idea behind it is simple: when your "bully" thinks you are about to give up, double down and show them you're much tougher than they think you are!

David found out about this trick when he was training to become a SEAL.

No matter how much his supervisor was trying to break him, it seemed it only made him tougher.

When his leaders understood they wouldn't manage to weaken David, they left him be.

4. The Calloused Mind

The calloused mind is a practice that helps you double down when the temptation to quit is the strongest.

Instead of thinking about how much you want to stop, remember every painful moment in your life, every humiliation, every time you've suffered, and realize that these weren't punishments to bring you down, but obstacles to fortify your mind and body!

Switch the way you look at your past. Don't look at it as a tragedy. Look at it as a training ground!

Every obstacle made you strong and prepared you for this very moment. It prepared you to endure the pain and go further than you ever have, to push your limits!

When you think about these things, something will happen in your brain. You will tap into your sympathetic nervous system, the pain will decrease and you will gain motivation.

Always be optimistic. A negative outlook will not trigger the calloused mind.

5. On Accepting Yourself

The majority of people lead mediocre lives due to psychological issues they have not resolved. Their trauma is preventing them from being their best selves.

The only way to solve a trauma is to revisit it, write it down, accept what happened, let go, and move on.

When you go back to your past and identify all of the moments when you were weak, you free yourself from them and accept what happened.

Accepting and making peace with your past helps you accept yourself in the present.

6. The Cookie Jar

The cookie jar is intimately linked to the calloused mind.

The cookie jar is a mental pool containing every happy moment and every unhappy moment of your life.

It helps you answer the question “why am I doing this” when you are in the midst of a difficult challenge.

It helps you understand that on one hand, the painful moments made you who you are so you can ultimately triumph; on the other hand, the cookie jar is a promise for many more happy moments like the ones you’ve already had.

It’s the ultimate justification for the pain you’re enduring.

7. No Shortcut

Mastery does not tolerate shortcuts.

Shortcuts exist to get better results with the same amount of pain/effort.

It can neither scale nor work in the long term.

The only way to go beyond your limitations is to do more, and better.

8. The Governor

The governor is an imaginary psychological limitation that prevents us from exploiting 100% of our capacity.

It’s the reason why we don’t achieve more.

The governor is that little voice in our head that tells us we suck and that we won’t make it.

You need to do two things to take off your governor and access your full potential:

- I. Don’t listen to your voice.**
- II. When you feel like you cannot keep moving anymore, push just 5%-10% more. Doing so, you will unlock more potential.**

9. The 40% Rule

Goggins believes that most people live up to 40% of their potential.

The remaining 60% is locked due to the governor. People never push above their capacities because they're weak.

The reason why they're weak is that they live in an environment that is too comfortable.

It makes them lazy. It makes them hate pain. And it prevents them from pushing further.

If you want to go over your 40%, you need to:

- I. Stretch your pain tolerance
- II. Let go of your identity
- III. Let go of your self-limiting beliefs

10. What If?

What if is Goggins' last trick.

To everyone that ever doubted you — including yourself — the most powerful thing to answer is *what if*.

What if it was possible? What if they were wrong? What if you were right?

What if opens the door of possibility. It gets you to try and see what happens.

It keeps you moving forward.

It prevents you from quitting.

Step 212 - Kobe Bryant On Mental Toughness and Work Ethic

1. Books Kobe Bryant Toughness and Work Ethic

- I. Relentless_ From Good to Great to Unstoppable By Tim Grover.**
- II. Winning_ The Unforgiving Race to Greatness By Tim Grover**

2. Kobe Bryant ON Valuetainment and his Toughness

- I. Be Extremely Curious, trivial things should not pull my attention. It had the things that I have a purpose I am interesting in, and anything outside the line, you should not have a time for.**
- II. Have focus on one thing , and do not be multitasking or distracting yourself with trivial things.**
- III. Every thing you see, like tv shows, reading books, people I talk to. Everything I will learn to Master My craft, when you have this point of view, you literary the world becomes your library to help you to become a master of your craft. Because you know what you looking for the world gives the exact information you need to prepare for mastering the craft.**
- IV. Never hang out with people just to hang out.**
- V. Get over yourself, it is not about you, and you feel embarrassed, it not that important. Then you need to ask yourself why this mistake happened. Look at this with rationale and alter anything needed to not make the same mistake.**
- VI. Kobe Making Decision: A. Does the person understand the business. B is the business that you can help in some form of shape. C what is the barrier of entrance to the business. D Entrepreneur itself, if he obsessed, do the company have a culture that you believe is sustainable, are these leaders that you believe in. E do they have a culture of obsessiveness.**
- VII. If you tired, then suck it up and go further and no complain and no excuses. You need to lead by example. If there is an obstacle, then you need to show to kids that this will be overcome. Parents needs to lead by example, not just talking, but show them.**

- VIII. When you do Deep work, Study and as employee working, switch the mind to something else, switch the mode to something else. Maximus from Gladiator, picking up the dirt, smelling the dirt, it is go time. This is mental switch. Put Yourself in the cage and focus on the task. Once you finish, you become different person. While you in the cage, do not let distraction take away focus from you.
- IX. Pain Tolerance is one of the biggest factors of someone who can handle pressure. The whole idea pressure is pain. The Pain Can be a lot of other things like embarrassment, real pain. This is one of the way is to measure someone toughness.
- X. Preparation: tough people also prepares for the pain that is going to come. Preparation is a measure of toughness.
- XI. Toughness is also practice the endurance of the pain. Practice, Practice, Practice.
- XII. Do not advertise your pain to the world to know your pain. Man are tough are not looking for attention.
- XIII. Life is a constant Test on Daily, Weekly, monthly, Yearly Basis. When you been tested, this measures your toughness.
- XIV. Soft Person does not have backbone, and when they are cornered, pushed and shoved they quit. Soft claims their values, but when the tough times comes, compromise their values. Ask Myself How Do I react when the tough times comes.
- XV. Tough people do not over react to the problem and issues.

3. Kobe Bryant 10 Rules of insane work Ethic:

- I. Be Driven:** be driven and always try your best in any situation. If you tired, then suck it up and go further. And no complain and no excuses.
- II. Work Helps You grow:** Outwork everybody else on the team, or in Gym.
- III. Outwork Everyone:** Try to prove that I was better then anybody else in the craft. Wake Up Early and Go To Bed Early. Get the competitive advantage by Waking up early and do the work.
- IV. Love What You Do**
- V. Make One Move at A Time:** You have to put one foot in front of the other. Focus on the day task. You have to have a plan in place, how you going to improve for each day to get better and stick it to the plan and trust the plan, that this brings to the end result.
- VI. Have A schedule**

4. Kobe Bryant 10 rules of success:

- I. Make Sacrifices:** We are all can be Masters of our craft, but you have to be willing to make Sacrifices, that comes along to make that decision.
- II. One move at a time:** you can draw lessons from different things, as the world become your library. You could see the vision of the end result, you need to make one step at the time
- III. Trust your skills:** You have to be fearless to take the shots, because if you miss the shot, then you have to deal with criticism. Trust your skills, trust the work you put in.
- IV. Use your scars as weapon:** use the things in life, use those moments as weapons
- V. Focus on each day:** You have to put one foot in front of the other. Focus on the day task. You have to have a plan in place, how you going to improve for each day to get better and stick it to the plan and trust the plan, that this brings to the end result.
- VI. Do not be afraid of confrontation:** do not be afraid of confrontation to get us, where we need to go. If you are leader, you not just singing Kumbaya, but held others accountable, even having that moment being uncomfortable.
- VII. Be competitive when it's hard:** It takes true competitive person to get up when you down and continually compete.

VIII. Just keep going:

IX. Thrive on being outsider

X. Compete with yourself: Have competitive drive to be better everyday. Put hard work on daily basis. Work on your craft day in and day out on the craft when no one is watching.

XI. We don't quit. We don't cower. We don't run. We endure and conquer

Step 213- Michael Jordan Toughness

1. Books Michael Jordan Toughness and Work Ethic
 - I. Relentless_ From Good to Great to Unstoppable By Tim Grover.
 - II. Winning_ The Unforgiving Race to Greatness By Tim Grover.
2. Good Competitor evaluates his opponent, understanding for what he really is. Never give the competitor confidence, try take all the time. Mentally I need to trick myself to find the motivation. I need to look inside myself try to find the challenges, I need to look who I am competing against.
3. Practice if you are playing in the game, so when the moment comes in the game, its not new to me. That's the reason why you practice, thats the effort, so when you get to that moment, you do not have to think, instinctively things happen.
4. Jordan's 10 rules of success:
 - I. Keep Working Hard: Everyday be the first person there, before the son, Jordan would be there and the last person leave every night. Work to get better every single day on the craft.
 - II. Ignite the fire: Awaken a person inside of me to excel to be one of the best or be best/
 - III. Be different: want to excel in my craft and isolate in my craft from everybody else, that I am more than just a few dimensional.
 - IV. Fail your way to success: Jordan missed more than 9000 shots in his career, lost almost 300 games. 26 times he been trusted to take the winning shot and missed. He failed over and over in his life. That is why he succeed/
 - V. Have high expectation: see always where to improve in the craft.
 - VI. Be positive
 - VII. Be who you were born to be.
 - VIII. Have vision: mentally have a vision, to finish that we have to obtain. This will test your will to succeed
 - IX. Stop making excuses
 - X. Practice: Practice if you are playing in the game, so when the moment comes in the game, its not new to me. That's the reason why you practice, thats the effort, so when you get to that moment, you do not have to think, instinctively things happen.

Step 214-Tim Grover and Work Ethic

1. **Books By Tim Grover Toughness and Work Ethic**
 - I. **Relentless_ From Good to Great to Unstoppable By Tim Grover.**
 - II. **Winning_ The Unforgiving Race to Greatness By Tim Grover.**
2. **Different between coolers, closers and cleaners**
 - I. **Coolers, Closers, and Cleaners: Good, Great and Unstoppable.** For his own thinking, Grover devised a three-tiered system that can be applied to any group of individuals: your friends, your family, your co-workers, your team, etc. As Grover says: “Everyone has a different definition of personal success: some people allow life’s circumstances to decide what they want and say “good enough” when they get it, and then there are a select few who can’t even define success because they keep raising the bar on what that means. Coolers, Closers, and Cleaners.” He finds that most people are Coolers, a small percentage are Closers and perhaps there may be a Cleaner in the group. But once you meet the Cleaner you will never forget him/her. Seeing as how the rest of this post will be focused on the relentless 13, which are the traits of cleaners, we will only discuss coolers and closers here and save cleaners for later. Grover describes...
 - II. **COOLERS** as: “A Cooler is careful; he waits to be told what to do, watches to see what everyone else is doing, and then follows the leader. He’s a mediator, not a decision-maker; he’s not taking sides unless he’s forced to. He can handle a certain amount of pressure when things are going well, but when things get too intense, he kicks the problem over to someone else. He can make a huge play, but he’s not ultimately responsible for the outcome. He’s the setup guy, keeping things cool until the Closer or Cleaner can take over.”
 - III. **CLOSERS** as: “A Closer can handle a lot of pressure; he’ll get the job done if you put him in the right situation and tell him exactly what you need him to do. He’ll study all sorts of scenarios so he can anticipate what might happen, but he’s uncomfortable when faced with something unexpected. He seeks attention and credit, and he’s very aware of what everyone else is doing and what others think of him. He loves the rewards and perks associated with his fame and would choose financial security over winning

or success.” The main difference between the three is that the Cleaner never needs a kick in the ass while everyone else does and we will see why that is in the next section regarding the relentless 13, or the 13 traits of a cleaner.

- IV. The Relentless 13 Grover explains that every Cleaner he has ever known has some combination of the traits below. Not every Cleaner has every trait all the time, but every Cleaner has experienced at least some of them at some point. He admits that some may intrigue you and some may repel you, but each of the relentless 13 will contribute to your ability for being relentless. By the way, he labels each #1 as none is more important than another. In case you are wondering why he calls them “Cleaners”, it’s because rather than blaming others when something goes wrong, they take responsibility, clean up the mess, and move on. While Grover dedicates a full chapter to each of the relentless 13, I will simply touch on an important idea that I took away from each. And if you want to delve deeper, which I recommend, you can check out the entire book. The relentless 13, when you’re a cleaner...

3. Tim Grover 13 rules of Relentless (cleaner):

- I. You keep pushing yourself harder when everyone else has had enough. Grover touches on the exact point we made in a recent post in that to experience success it is critical to **be comfortable being uncomfortable**. In other words, cleaners do stuff every day they don't want to do, pushing past apathy, fear, and laziness.
- II. You get into the Zone, you shut out everything else, and control the uncontrollable. Grover explains cleaners with respect to the Zone as follows: "But once a cleaner steps into the Zone, he's detached from everything on the outside. Whatever else is going on—personal, business, anything—it can't affect him until he's ready to return. That, by definition, is the Zone. No fear, no intrusion. Total concentration. You're not thinking, because thinking turns your thoughts on to everything, and the Zone is about the opposite, turning your thoughts off to everything except the task at hand. Thinking takes you away; the Zone keeps you where you need to be."
- III. You know exactly who you are. This one is about instinct and taking action. Cleaners are so ready and so prepared that they take what they have learned, and their thought moves straight to their gut, instinct takes over and they put it into action.
- IV. You have a dark side that refuses to be taught to be good. Grover believes all cleaners have a dark side somewhere deep within them. He describes it as "Deep inside you, there's an undeniable force driving your actions, the part of you that refuses to be ordinary, the piece that stays raw and untamed. Not just killer instinct." He believes that cleaners embrace their dark side by being able to drop all their inhibitions and allow themselves to do whatever it is they need to do, the way they want to do it – instinctively and without fear.
- V. You're not intimidated by pressure, you thrive on it. He believes being called "clutch" is an insult and that there is no such thing as having a "clutch" gene. The reason being is that being called "clutch" means you only step up at the last minute while being a cleaner means you are always stepping up. You are always keeping the pressure cranked up, but it is internal pressure as a cleaner is always hardest on themselves.

- VI. When everyone is hitting the “In Case of Emergency” button, they’re all looking for you. Cleaners always know they will be ok no matter what happens they are confident that they can handle anything. If things don’t work out, they recognize what isn’t working and are flexible enough to adjust, adapt and move on.
- VII. You don’t compete with anyone, you find your opponent’s weakness and you attack. I like how Grover contrasts cleaners with coolers and closers when he says: “A Cooler wonders what’s going to happen. A Closer watches things happen. A Cleaner makes things happen.”
- VIII. You make decisions, not suggestions; you know the answer while everyone else is still asking questions. Cleaners make a plan that reflects their goals and interests and then they execute. As he says: *“Figure out what you do, then do it. And do it better than anyone else.”*
- IX. You don’t have to love the work, but you’re addicted to the results. Being a cleaner involves a lot of hard work and part of it is understanding what you need to sacrifice to do that work. You need to be able to keep your eye on the mission and control whatever is trying to pull you away from it. Cleaners are not distracted by instant gratification as they are focused on the long-term payoff.
- X. You’d rather be feared than liked. Cleaners are very upfront and straight-shooters and will tell you what they think whether you like it or not. I love how he says: “Fear and respect: let them know you were there by your actions, not your words or emotions. You don’t have to be loud to be the focus of attention.”
- XI. You trust very few people, and those you trust better never let you down. Cleaners are surrounded by those who want them to be successful and who understand what it takes to be successful. Those who aren’t following their dreams themselves likely won’t support you in your pursuit of yours and they will tell you the same negative stuff they tell themselves.
- XII. You don’t recognize failure you know there’s more than one way to get what you want. Cleaners are always trying to improve. They don’t believe in failure because they never believe anything is over. If something doesn’t go as planned, they learn from it, change direction and try a different way.
- XIII. You don’t celebrate your achievement because you always want more. A Cleaner believes they have zero limitations and are always demanding more

of themselves than anyone else possibly can. This means that they are always thinking of how they can do more and get better. As Grover says: *“The drive to close the gap between near-perfect and perfect is the difference between great and unstoppable.”*

4. Winning by Tim Grover

- I. Whether you're an athlete with championship dreams, an entrepreneur building a business, a CEO managing an empire, a salesperson closing a deal, or simply a competitor determined to stand in the winner's circle, *Winning* offers thirteen crucial principles for achieving unbeatable performance. This book reveals the truth about the obstacles and challenges that stand between you and your goals: Winning never lies. Winning knows your secrets. Winning wages war in the battlefield of your mind. Winning wants all of you. And more. If you're addicted to the taste of success and crave more, then you're ready for *Winning's* results-driven performance strategy. And if you're already winning and want to learn how to execute at a level that will establish you as one of the greatest—so you can own not just *this* moment, but the next, and the next—this book will show you the path.
- II. Kobe Bryant. Everything Kobe did was about winning. Winning is everywhere. Every moment. You have the opportunity to win. Grover describes winning as brutal, never ending and relentless. Any book with a title like “10 easy steps to winning” is a fraud. There is nothing easy or simple or predictable about winning. The book doesn't tell you what to do. You know what to do. *Winning* paints a picture of exactly what winning is, and the kind of attitude you will have to adopt if you want to win again and again and again. Winners, or “cleaners”, never stop chasing greatness. There is always more.
- III. THE LANGUAGE OF WINNING. Winning doesn't bullshit. Grover isn't about “motivation”. Anyone who really wants to win drives themselves. It is a given. Anyone who needs a book or a speech to give them temporary motivation is missing the point. The book isn't here to tell you that “You got this!” or “everyone's a winner!”. The book is about showing you the brutal, unforgiving, uncertain path that anyone who really wants to win must walk down. The unbearable loneliness, exhaustion and fear. There is nothing normal or typical about the lifestyle of a real winner. Normal people don't stand out. Normal people go where everyone else has gone. Winning is in everyone, but for most people, it will never be shown because of all of the fear and worry and doubt. The way you talk about winning will show you where you are at with regard to actually winning. “Look at these definitions

of winning again. Uncivilised. Hard. Nasty. Unpolished. Dirty. Rough. Unforgiving. Unapologetic. Uninhibited. Everything. If that describes your journey, and how you attack your goals, we are speaking the same language.”

5. 13 Definition of Winning

- I. Winning makes you different, and different scares people. Grover talks about the importance of knowing how to think for yourself, as opposed to being told what to do and accepting the norm. Every great development in humanity came as a result of someone thinking for themselves and not just accepting the world as they were given it. “Winning requires you to learn, and then question what you learn, and then learn more. You have to be willing to challenge what you’ve been taught” Grover also talks about the concept of non-negotiables, and how they can hold you back in your journey if you are not careful. For him, the only non-negotiable is performance. Everything else is there to be looked at and scrutinised. Nothing is off-limits for people who really want to win.
- II. Winning wages war on the battlefield in your mind. “I don’t have a better way to say this. Winning Fucks with your mind. It just does” The writer talks about the non-stop mental warfare that takes place in the mind of every winner. You are exhausted and impatient and on the edge all the time, even when you rest. The message of this chapter reminds me of a quote I came across once: “Hustlers don’t sleep. They nap” Your brain is like a minefield that is yours to dominate. You must be aware of your own insecurities, distractions and weaknesses if you are going to stay in control. “If you decide something is going to be a problem, then it’s going to be a problem” This is a chapter about the mindset of a winner, but not in that positive rah rah self help sense. It is a real, honest look at the lengths we have to go to if we are to stay on the winning path. Grover also talks of how winners control absolutely everything that they can, with the expectation that there will be plenty of unexpected challenges that they will have to overcome in the moment.
- III. Winning is the ultimate gamble on yourself. This chapter is really about confidence. The chapter details the similarities and differences between Kobe Bryant and Michael Jordan. Grover knew these players personally probably better than anyone in basketball, and his insight is pretty cool. He talks of how for all of their differences, both Kobe and Michael shared unshakeable confidence in themselves and their ability to get the job done when the time came. They never buckled. Their ability to bounce back from a loss. Their ability to ignore the negativity of the media. Their ability not to

be overpowered by more physical players. They always knew that they could come out on top. It defined their greatness. This belief went way beyond basketball. Michael became the first player to become the majority owner of a team after he retired. He started numerous business ventures. He competed on the golf course. Kobe learned 5 languages. "Everything he did was about his massive belief in himself" Grover talks of how truly confident people cannot be broken. They have been beaten down and broken over and over by life and their goals, and they have ploughed through every obstacle that life has thrown at them. People like that truly back themselves when the pressure is on.

- IV. Winning isn't heartless, but you will use your heart less. "Winning has a price, and that price is that your mind must be stronger than your feelings" People talk about how brutal Michael Jordan was in training with his teammates. To the untrained eye, you might be forgiven for thinking that he was a bit of a c*nt. But think about it. He won 6 rings. He is etched in basketball history, and he bought his whole team with him. We all know about Scottie Pippen, and Steve Kerr, and Dennis Rodman, because of the rings that they won under the leadership of Michael Jordan. That kind of greatness doesn't have the time to worry about your feelings and emotions. Your mind knows exactly what to do. Your weakness often comes from your feelings. You know you need to work out. Your feelings get in the way. You know that you should consistently post. You feel exhausted. Self-control is all about controlling your thoughts, in order to control your emotions, in order to control your actions. Control what you can control. Michael wasn't emotional when he was angry. He was cold and unemotional. He was aggressive, but he was absolutely in control. That is a dangerous combination.
- V. Winning belongs to them, and it's your job to take it. This chapter is all about competition. Have you ever been accused of being overly competitive? Or having a competition problem? Grover wants to challenge you to be OK with that. The greats never stop. There is always another challenge. Why do you think all the great boxers keep fighting until they are a shell of their best selves? It is in them to fight and compete. There is nothing else like it. Competition drives us all. To compete every day is to get the most out of every single day. We are all hard-wired to win. You

cannot teach competitiveness, and you cannot make other people want to win. You may inspire it, but ultimately it is a completely internal and personal fight. You must want to win, with all of your being, for yourself over anyone else.

VI. Winning wants all of you; there is no balance. “Time for everything equals time for nothing” Winning wants all of you. It demands obsession. The whole work-life balance thing doesn’t really mean a lot to people who badly want to win. When you are obsessed with achieving greatness in one area, that usually comes at the expense of most of the things everyone considers normal and healthy. Being the best requires hard sacrifices, and it is never going to be easy. There is no perfect future where you can have greatness in your field, and a great family life, and great holidays, and loads of sleep, and loads of friends. Winning wants all of your time and attention. There is no balance for those who want to win. Stop looking for it, and stop feeling guilty about your lack of it.

VII. Winning is selfish Why is it so wrong to be considered selfish? Self literally defines who you are. To invest in yourself, love yourself, be yourself, all sound like a great thing. To be selfish has such a negative ring to it. But what is the difference really? How is it a bad thing to be concerned with your own results and success? This chapter convinces us of the absolute necessity for someone who wants to win to be selfish. The chapter also makes an important distinction; there is a difference between selfish winners and selfish losers. Selfish losers take from everyone, and everyone else is better off without them. If you are selfish but not concerned with winning, then you are just prioritising your own pleasure and impulses. Selfish winners give to themselves first, so that they can ultimately give to the world. They give themselves the time, space and permission to achieve what they want to achieve because they know that their winning can lift up those around them. In order to be the most charitable person in the world, you first have to put some serious money behind you! You can’t create your own wins without first prioritising your own goals and dreams. Separation is power. Separation is freedom. Winning is an investment. If you want to win, you must be selfish and invest. If you are not willing to invest in yourself, why should anyone else?

VIII. Winning takes you through hell; if you quit, that's where you'll stay. People think of winning as this triumphant celebration that solves everything. According to Grover, that is true only for a moment. But stay in that moment too long, and it will be the last time you ever get to experience it. Winning takes a brutal trip from the bottom. You must toil, and grind, and think, and push relentlessly through mud and sacrifice. If you don't quit, you will win. It will feel incredible for a moment. Do you want to win again? Do you want more? You must go right back to the bottom. You're not a "winner" now. Your next success must be earned, just like your last. It is relentless. Even when you do win, you are still scarred by all that you've had to go through to get there. The personal sacrifice. The lack of friends. The neglected family life. The lack of time off. The one-dimensionality of your existence. The journey to winning is so brutal, that anyone who will manage it time and time again must be nothing short of addicted.

IX. Winning is a test, with no correct answers Everyone experiences fear. It is a fact of life. But fear and doubt are very different. When you feel that fear, do you question your ability to get there in the end? Or do you think about how far you've come, about all the preparation you've put in, and do you stay confident in your ability to ultimately handle whatever's coming your way? This is the difference between doubt and fear. "I have self-doubt. I have insecurity. I have fear of failure. I have nights when I show up at the arena and I'm like my back hurts. My feet hurt. My knees hurt. I don't have it. I just want to chill. We all have self-doubt. You don't deny it, but you also don't capitulate to it. You embrace it." Kobe Bryant Fear is about playing to win. Doubt is about playing to not lose. Fear is pressure. Doubt is panic. Fear says you might win. Doubt says you might lose. Ultimately, winning is a terrifying leap of belief in yourself. According to Grover, there are 4 components that will determine your ability to handle fear. Talent, intelligence, competitiveness, and resilience. He goes into detail about the importance of all 4. Spoiler alert: talent is really common, and resilience is really rare.

X. Winning knows all your secrets One of Grover's most popular ideas from his first book is the idea of the dark side. We all have that side of ourselves that the world doesn't know about. When we are alone at night, there they are. All your mistakes, your fears, the voices in your head, all real and

uninhibited. The writer talks about the genuine power that comes from completely incorporating your dark side and accepting your full self, rather than feeling bad or trying to change everything that isn't completely spot on. "Deep inside you, there's an undeniable force that drives your actions. The piece of you that refuses to be ordinary, the piece that stays raw and untamed. Not just instinct, but killer instinct. The kind you keep in the dark, where you crave things you don't talk about. You don't care about how it comes across to others because you know this is who you are and you wouldn't change if you could. The dark side is your fuel. Your energy. It excites you. Keeps you on the edge. Recharges you. Fills your tank. Its an addiction as powerful as your addiction to success" Kobe's dark side was the black mamba. When he stepped onto the court, he wasn't the Kobe Bryant that had legal issues and family problems. He was a cold-blooded killer that would dominate anyone stupid enough to play against him.

- XI. Winning never lies. Winning knows the truth, and it wants you to admit it. There is nothing subjective about winning. It is a score. An amount of money. A number on a scale. A decision. It doesn't matter how hard you tried, how many people were with you, or how talented you are. Ultimately it is black and white. We love to lie to ourselves: "We deserve more" "The score didn't reflect the game" "Next year is our year" "We're going in the right direction" If these statements aren't rooted in anything measurable or objective, they are usually just excuses for us not doing what it took to actually win. You can put your time into convincing yourself that you are a winner, or you can put your time into being honest with yourself, changing your course, taking the right actions and then actually winning. You cannot do both. This is one of my favourite ideas from this whole book: Stop talking. When you win, you don't need to talk. If you win, that will do the talking for you. If fake it till you make it is your strategy for success, you aren't going to get anywhere. Winning doesn't buy your lies, and most people don't either.
- XII. Winning is not a marathon, it's a sprint with no finish line. Don't manage your time. Manage your focus. Think about the Olympic marathon. These are the worlds best athletes. When they are competing for the gold, do they chill for any 1 of those 26 miles? Is there ever a point where they just take it easy? They are patient, they aren't stupid, but they squeeze every second

that they can out of every mile of the race. Slow down. Take your time. Pace yourself. If your goal is to finish, this language makes sense. If your goal is to win, this language is stupid. "Rome wasn't built in a day. No, it wasn't. It was built every single day, for thousands and thousands of days" Many people are intrigued by the massive success of someone like Kobe Bryant. How was he able to achieve just so much? According to Grover, it was mainly due to his rare ability to focus on whatever it was he wanted, unfalteringly, until the moment he got it. He didn't party. He didn't have hobbies. He trained, and then he recovered, and then he trained, all the way up to the last game of the finals. There was no slowing down. "I never lost a game, I just ran out of time" Michael Jordan Winning doesn't care if you don't have time. Winning expects you to make time. If you've only got so much time to achieve what you want to achieve, all you can do is choose what you focus on. If you want to win that badly, all of your focus should be spent doing what it takes to win.

XIII. Winning is everything "Long term goals are great, but long term isn't promised to anyone. Your skills and energies have an expiration date. If you want something, go get it now." Grover talks in this chapter about the importance of a sense of urgency. He reckons it is ultimately the difference between those that win and those that watch others win. Kobe's impatience was legendary. Zero tolerance. Ultimately, winning is your legacy. It is what you've done. It is the mark you've left on the world. Every day, your time grows shorter. Tim Grover's message is simple: Do everything. Experience everything you want. Go and achieve your goal. Do not settle or slow or pace yourself. Push. Life is a daily campaign against laziness and the urge to quit. We are all human. It would be so easy to just fit into normality. But if you are going to win, you must keep going. Every day, you keep going. The pursuit of winning is what life is about. It is the pursuit that costs everything but gives everything.

6. Books on Mental Toughness.

- I. Develop Mental Toughness to Perform.**
- II. Develop mental toughness.**
- III. Self Discipline mastery.**
- IV. Execute Toughness, the leadership performance.**
- V. Intensional Mindset, developing Killer Instinct.**
- VI. Mindset of Champion.**
- VII. Mamba Forever.**
- VIII. Mental Toughness for Runners.**
- IX. Self Disciplinary.**

7. Books on Work Ethic.

I. Christian Authors.

- **Luther on Vocation.**
- **Teaching Of Luther and Calvin About Ordinary Works Part 1 and 2.**
- **Christian Work Ethic.**
- **A THEOLOGY OF BUSINESS: A REFORMED PERSPECTIVE ON THE BASIS AND APPLICATION OF CHRISTIAN ETHICS IN BUSINESS.**
- **TOWARDS A CHRISTIAN ETHIC OF WORK IN SOUTH AFRICA.**
- **Calling A biblical Perspective of Work.**
- **Every Good Endeavor by Timothy Keller.**
- **Christian AND Work.**
- **5 Commands for Business Ethics.**
- **Calling of Faith and Work.**
- **Treatise of Vocation**
- **Quakers in the Contemporary Workplace.**
- **Religious Tradesman.**

II. Non Christian authors.

- **Revive Work Ethic.**
- **How to Build Strong Work Ethic.**
- **Work Ethic for Development Profesional**

8. Work Ethic:

- I. Be Predictable:** Good Work Ethic is the person who is predictable every day, like you show up at 8 am and leave at 17h and do this every day. Show up every day without disruptions.
- II. Consistency:** You show up every day consistently. You keep show up and keep doing the work.
- III. Preparation:** Do Proper Planning A Month, Week, Few days and night before which helps to prevent poor performance. The most prepared wins.
- IV. Do More:** Stay back and do more work, and put effort to achieve the results I want. If the person makes 100 calls a day, you need to do 200 calls a day. If the person sells 20 products, you sell 40 products. If somebody practices 3 hours, then you do 5 hours. Do A little bit more.
- V. Now Mentality.** Subscribe to the Now Mentality. Means if you want to call tomorrow, then call it now and today.
- VI. Find Running Mates:** Find a person with the same mentality, who pushes you to do better and more.
- VII. Don't fall for Work Smart:** Do not fall for the work smart only concept. You need to work very hard.
- VIII. Cut off Distractions:** Cut distractions, do not involve into office politics, but come to do performance. If there is office politics, then you go perform instead involve into office politics.
- IX. Absolute Focus:** Train your mind to Focus. Use Deep Work by Cal Newport to do the deep work. The absolute focus is when you take away distractions, and start to focus on the task of deep work. Example Reading a book, you need to read as many times as possible to try to understand and Follow and Apply Rules of reading to that reading or task. Train your brain to be focus , because your brain is muscle. Stop Making Excuses that you cannot focus, but practice focusing on daily basis.
- X. Have To Do List:** Good Work Ethic person has a to do list. In my Case Use deep work routine with 80/20 RULES, Eat ThatFrog AND Eisenhower Matrix this is my to do list, as it shows exactly what needs to be done and list of TO DO List*
- XI. Eat Right:** Work Ethic requires energy for you to last long time, stamina, efficiency. Use Keto Diet, Intermittent Fasting and Exercise on Daily basis.

XII.Plug the Leaks: Plug the leaks is the time wasters in my life and my work life.

XIII.Cut the Fat: cut the fat means that the works that do not need to be done or somebody else can do it. Turn off the Facebook and snapchat and social media. Ask myself if the work I have done and effort put, lead to increase in the results?

XIV.Drop Perfection: Do not seek for perfect time, or perfect environment.

XV.Avoid burnout. Have your own Escape.Gift Yourself

9. Tim Grover

- I. Master of your craft and be expert of my craft. Do not try to become experts of everything. Do What You do. Do not Jump from one thing to another. You have to Master whatever you are going to Master. Once you Master one part of the craft, then move to another part of your craft and master that part of the craft.**
- II. Competition never ends. The winning then manifest into something else.**
- III. Do not stay in the middle and get out of the comfort zone.**
- IV. Winning doesn't have any friends, it has allies.**

10. Advanced Through Pain

- I. The pain period exists to allow us the opportunity to show how badly I really want to prove that I want it as badly as I say we do. To Back up our claims that we are who we say we are. The pain period where the all the growth occurs that's true whether we are talking about building big muscles, building big company or building vision. There is no way around the pain and the sacrifice and the work. The only way out is through. But here the motivation part, the only way you can fail is if you quit. That's literally the only way that you can be stopped. As virtually impossible to fail- just don't quit. Don't quit and you cannot fail**

Step 215-Focus and Books On Focus For Deep Work

1. Books on Focus and Concentration For Deep Work.

- I. Atomic Habits By James Clear**
- II. Deep Work, Rules for Focused Success in A distracted World.**
- III. Focus on Hidden Drive of Excellence.**
- IV. 18 minutes find your focus master distraction-and-get-the-right-things-done.**
- V. Focus-use-the-power-of-targeted-thinking-to-get-more-done.**
- VI. Master-of-one-find-and-focus-on-the-work-you-were-created-to-do.**
- VII. The-art-of-being-indispensable-at-work-win-influence-beat-overcommitment-and-get-the-right-thing.**
- VIII. Focus__A_Brief_Guide_on_How_to_Improve_Focus_and_Concentration.**
- IX. Power Of Focus**
- X. Hyperfocua**
- XI. How to Become Straight A student**
- XII. Ultralearning**

*Part 36: Deep Life, Deep Work
and Benjamin Franklin Daily
Routine*

Step 216-Deep Life, Deep Work and Benjamin Franklin Daily Routine.

Documents That Will Stay At Home and Documents That Will Be Brought to Work.

1. Documents Leave At Home.

- A. Identify End Goal.
- B. Quarterly Value Plan.
- C. Quarterly Planning Or Strategic Planning.
- D. Project Tracker.
- E. Task List.
- F. Values Document.
- G. Personal Code of Conduct.
- H. Professional Code of Conduct.
- I. Skills.
- J. Ideas Book.
- K. What Sport Training To Do On Daily Basis.

2. Documents Bring To Work.

- A. Daily Planning.
- B. Work NoteBook.
- C. Work Priorities and To Do List.
- D. Weekly Planning.
- E. Weekly Value Plan.
- F. Calendar. This includes, Professional, Academic and Personal.
- G. Habit Tracker.
- H. Reflect and Review Journal.
- I. Headphone.
- J. Phone.
- K. Documents How to do TimeBlocking.
- L. Deep Life and Deep Work.

M. Timeframe For The Different Tasks.

N. Document On What Sport Training Do I Do On Daily Basis.

Documents That I will Use on Daily and Weekly Basis and Other Times For Reading or Listen.

1. Documents Use On Daily Basis.

- A. Deep Life, Deep Work, Deep Studies AND Benjamin Franklin Routine Document (Schedule DAY).**
- B. TimeFrames For Different Tasks.**
- C. Rules of Reading 1-12. Below are Complimentary Books Used with Rules of Reading.**
 - **Rules of Reading 10a to 10k.**
 - **Logic Books 1-8.**
 - **Grammar Books 1-3.**
 - **Writing Books 1-8.**
- D. Bible Study and Devotional Books 1-7.**
- E. Marriage Books.**
- F. Stoicism.**
- G. Deep Work and Deep Studies.**
- H. Studies And Learning.**
- I. Reflect, Review, Journaling and Visualisation Document.**
- J. Health For Checking food, minerals and vitamins to eat and Drink.**

2. Documents Use On Weekly Basis.

- A. Value , Code Of Conduct and Skills Documents By Which I live.**
- B. Important Books 1-24**
- C. Communication 1-4.**
- D. Reflect, Review, Journaling and Visualisation Document.**

3. Documents Use For Other Time Basis.

- A. Parenting 1-13.**
- B. Habits Books 1-6.**
- C. Church Books.**
- D. Mental Model 1-8.**
- E. Finance. Or Any Other Topics and Books.**

Stage 0:Core Systems

First Things First: Your Personhood Precedes Your Productivity. Good productivity system is a tool to serve the whole person. Your personhood comes first! Your productivity system is there to serve you, not the reverse.

Below are summaries of the **Two** main categories that contain the elements of my core systems: **Core Documents And Core Productivity**.

List Of The Items I need To Have.

Quarterly

- **Identify End Goal.**
- **Ruler.**
- **Quarterly Planning.**
- **Value Document: Values, Code of Conduct and Skills.**
- **Quarterly Value Plan.**
- **Work NoteBook.**
- **Work Priorities and To Do List.**
- **Project Tracker.**
- **Calendar.**
- **Deep Life and Deep Work and Benjamin Franklin Routine.**
- **Task List.**
- **Ideas Book.**
- **TimeFrames For Tasks**

Weekly

- Identify End Goal.
- Ruler.
- Weekly Planner Notebook.
- Habit Tracker.
- Quarterly Planner Notebook.
- Value Document: Values, Code of Conduct and Skills.
- Weekly Value Plan.
- **Work NoteBook.**
- **Work Priorities and To Do List.**
- Project Tracker.
- Calendar.
- What Sport Do I do On Daily Basis.
- **Deep Life and Deep Work and Benjamin Franklin Routine.**
- **Task List.**
- **TimeFrames For Tasks.**

Daily:

- Identify End Goal.
- Ruler.
- Daily Planner NoteBook.
- Deep Work NoteBook.
- Habit Tracker.
- Project Tracker.
- **Work NoteBook.**
- **Work Priorities and To Do List.**
- Calendar.
- Journaling, Review, Reflect Notebook.
- Weekly Value Plan.
- What Sport Do I DO On Daily.
- **Deep Life and Deep Work and Benjamin Franklin Routine.**
- **Task List.**
- **TimeFrames For Tasks.**

Core Documents

1. Discipline-Internally Powered Efficacy (Productiveness).

Rule 1- Check Disciplines Once A Year During My Birthday, and Review How I am Doing and What next Disciplines I need To Do It For Next Year.

Rule 2-Define your non-negotiable: Identify a few daily activities that requires Discipline that are crucial for your well-being and make a commitment to do them every day.

Rule 3-Take few things and think how can I make progress everyday. If it's too hard find something easier.

Rule 4-Set up organizational systems: Choose tools that will help you stay organised, such as a planner, calendar. Consistently use these tools to manage your time and tasks.

Rule 5-Create a routine: Establish a daily routine that incorporates your non-negotiable and gives structure to your day.

Rule 6-Get Metric And track if Done This discipline.Sometimes track the execution of these disciplines with metrics Such as Exercise or How many hours of Deep Word I have done today.. Sometimes I take a break from this tracking.

2. Values- External Powered.

In this Part of the Document I will Write My Roles and the Values by which I try to live each of them on Daily Basis.

Rule 1-Identify and Write Down List Of Roles and The Values You Associate With them and by which I Try To Live on Daily Basis. Take some time to think deeply about what values are most important to you.

Rule 2-Write My Roles and The Values By which I Try To Live Each Of Them On Daily Basis:

- I. Step 1- Identify Specific Actions, Specific Habits or Behaviour, that go with Actually living out your values.**
- II. Step 2- Write First Person Narrative, What or How I want to be or act in that role that narrative implicitly captures my value. This way of Writing Makes The Value Concrete. Example:**
 - A. Roles:** “I want to be the kind of Husband, Parent and friend who ...*A values-based behavior related to the role:* “...who listens when the people I love want to have a conversation with me.”
 - B. Concrete values-based action,** “When people I love want time with me, and I am just fiddling on the computer or my phone, I lock or shut down the tech toys and walk away, so I can be truly present with them.” (If I am working intensely on something, I might ask that we talk a little later.)
 - C. The key is that I’ve expressed my value as an action, a measurable behaviour:** I either turn away from scrolling through my phone and turn toward my family member — I live out that values-based action — or I do not.

III. Step 3-Example of Writing

1. Value:

- A. Example of Writing.**
- B. A Value Based Behaviour To The Role.**
- C. Concrete Value Based Action.**

Rule 3-Create a personal code: Write down your values and create a personal code that you will live by.

I. Step 1- Use the Words “Always” and “Never” to Help You Write Down a Personal Code of Conduct. Example.

A. I don’t commit verbal violence toward anyone, including myself.”

Rule 4-Review The Core Values on Daily, Weekly and Quarterly Basis.

Rule 5-Ask Yourself Am I following The Value Document. Are They Align with My Quarterly, Weekly, Daily Plan?

Rule 6- Add New Values and Personal Conduct in Value Document.

I. Personal Code Of Conduct.

A. Personal Life.

- Behavior.**
- Moral and Ethics.**
- Skills.**

B. Professional Life.

- Behavior.**
- Moral and Ethics.**
- Skills.**

**I Will Read or Listen Like AudioBook On Phone, On Daily Basis
And Apply To Create Daily Planning.
Stage 1-Core Productivity.**

1. Identify End Goals.

Rule 1- Identify End Goals in the Following Areas:

I. Powerful Goodness, Devotional Reading and Bible Study.

II. Family

- **Wife.**
- **Daughters.**
- **Other Family members.**
- **Relatives.**

III. Professional:

- **Career.**
- **Self Employment.**

IV. Sport and Self Defence.

V. Finance.

Rule 2. Map Out For Each Goal Viable Path To Reach it.

Rule 3. Divide The End Goals into Small Manageable Goals and Tasks.

Rule 4- Create and Write Manageable Goals and Tasks Every January for that Year.

Rule 5- Review and Journal Progress of Manageable Goals and Tasks Every Last Friday, Saturday and Sunday of the Month.

2. Create and Update Quarterly Value Plan.

Rule 1- I Need To Create Value Documents On Following Date:

- I. Identify End Goals. Page 11.**
- II. Deep Life, Deep Work and Benjamin Franklin Routine Pages 12-13.**
- III. To Create Quarterly Value Plan, I Need To Review and Analyse Value, Code Of Conduct and Skills Documents The Last Friday, Saturday and Sunday Of Quarter, to Create Next Quarter Value Plan.**
- IV. It Usually Takes Around 90-180 Minutes.**

Rule 2- To Create Quarterly Value Plan, I Will Review and Analyse The Following Documents:

- I. For Values Use Values and Code Of Conduct By Which I live Page 5-24.**
- II. For Behaviour and Moral And ethics in Personal Life use values and code of conduct and Skills By Which I live Page 25-38.**
- III. For Behaviour and Moral And ethics in Professional Life use values and code of conduct and Skills By Which I live Page 39-51.**
- IV. Skills I will Learn For Personal Life and Professional Life. Pages 52-82.**

Rule 3-After Review and Analysis of the Value, Code Of Conduct and Skills Documents, I need to Decide The number of Values, Code of Conduct and Skills I will do For The Quarter:

- I. Between 5-10 Values I want to Practice For Quarter.**
- II. Between 5-10 Personal Code Of Conduct, I would Like to Practice For the Quarter.**
- III. Between 5-10 Professional Code of Conduct, I Would Like to Practice for the Quarter.**

IV. Between 5-10 Skills, I would like to Learn and Practice for Quarter.

Rule 4-Write On the Quarterly Value Plan Notebook, Decided Values, Professional and Personal Code Of Conduct and Skills.

Rule 5- Add, Write and Mark in Calendar, Every Last Friday, Saturday and Sunday of Each Month, That I will Do Review of the Previous Quarterly Value Plan This helps to See If I am on The Track or I need to Do some Changes in My Schedule or Do Something Differently.

Rule 6-Review Every Part of Previous Quarterly Value Plan, If I am on the Track Every Last Friday, Saturday and Sunday of Each Month, By using All Parts of *Journaling and Review of A Month* Pages 2083-2086.

3. Update Career and Personal Strategic Plans (Quarterly Planning) Once Every Semester

Rule 1- I Need To Create Quarterly Planning On the Following Date:

- I. To Create Quarterly Planning, I Need To Review and Analyse Quarterly Value Plan, My Project Tracker and My Calendar, Work Notebook, Work Priorities on The Last Friday, Saturday and Sunday Of Quarter, to Create Next Quarter Planning.
- II. Usually it Takes around 90-180 Minutes To Create Quarterly Planning. I Will Read or Listen Like AudioBook On Phone, Every Friday, Saturday or Sunday To Decide 3 Values I Will Apply To My Life For That Week.

Rule 2- Every Quarter Planning is Created Based On The Following Documents:

- I. Identify End Goals. Page 11.
- II. Deep Life, Deep Work and Benjamin Franklin Routine Pages 11-19.
- III. Quarterly Value Plan Document.
 - Values I want to Practice for the Quarter.
 - Professional Code of Conduct, I would Like to Practice for The Quarter.
 - Personal Code of Conduct, I would Like To Practice for the Quarter.
 - Skills, I would like to Learn and Practice for Quarter.
- IV. My Project Tracker.
- V. Work Notebook.
- VI. Work Priorities Word Document.
- VII. TimeFrame For Tasks.

VIII.My Calendar.

- **Professional Calendar,**
- **Personal Calendar.**
- **Academic Calendar.**

Rule 3- Review and Analyse, Quarterly Value Plan, Project Tracker, Work Notebook, Work Priorities Word Document and Personal and Professional Calendars.

Rule 4-When Planning For Quarter, this planning must have intention.

Rule 5- Once the Review and Analysis of the Documents have been Done. Then Think, Decide and Write What Are The Most Important Goals and Tasks I Will Be Pursuing and Working Toward this Quarter.

Rule 6-Write Quarterly Planning In the Following Format: One Plan with two parts. One Part is for Professional Life and Other Part is Non professional Life.

- I. Step 1- General Principle: Better To Plan Less and Actually Carry Out. Do not Schedule Too Much on Quarterly Basis Have Realistic Schedule. Use Slow Productivity Approach To Setting Up Goals.**

Rule 7-When Lay out The Strategic Plan or Quarterly Planning For Professional Life and Non Professional Life, Have Values Document and Quarterly Value Plan. Then I need to Do The Following:

- I. Ask Yourself, are the Strategic Plan or Quarterly Planning for Professional Life and Non Professional Life Align with My Values in the Value Document And Personal Code of Conduct and Professional Code of Conduct and Skills. In other words I need TO watch my plans for pursuing those parts of my life in the way that it is true and Align to my Values, Professional and Personal Code of Conduct and Skills. If There is an Extended Plan, Below is information, That I need to Follow.**
 - A. Sometimes these will also link to an extended plan when I have a big enough, long enough pursuit that it might need its own space. In other words, if there is particular Big project or initiative that I am working, will describe in its own document and linked to it from professional Strategic Plan.**

Rule 8-Maintenance (How Will I update These Documents).

- I. I review my Quarterly Plan or Strategic Plans (and extended plans) once a week, preferably when doing my weekly plan). I can tweak them at any time, but I try to give them major overhauls roughly once a semester (fall, winter/spring, summer.**
- II. I will Review Values Document and Quarterly Value Plan: My Values, Personal and Professional Code of Conduct, Skills Once A Week, as Reminder of My values, Code of conduct and Skills in My professional and Personal Life. I need to See if I follow my Values and Code of Conduct and Skills that I decided to Pursue for This Quarter.**
- III. I sometimes maintain an idea notebook and/or digital idea storage system keeping thoughts on values and strategic plans. I should review this in detail, at the very least, when I do my strategic plan updates.**

Rule 9-There are Two Ways I will Write the Quarterly Plan. Choose One of the Way I will Do it. Embrace whatever format seems most useful for the particular Quarter you are planning.

Rule 10a: Either Plan My Quarter For Each Month, And What I will Do On that Specific Month Based On Time Available On Time Block On Quarter Planning.

Rule 10b. Or I will Plan My Quarter When, There is No Major Appointments, Meetings or other scheduled obligation that break up my Day, I will Plan based on simple heuristics: like 3 hours of deep work a day and a list of things to schedule each Month into the time that remains.

Rule 11: No Matter what Way Will I plan my week, the most important is Always Decide in Advance What I am Going To Do With My Week. These Decisions Look Different at the different time of the year, but what matters is that when it comes to my schedule, I AM IN Charge.

Example: Quarterly Plan #1

October

After weekly planning do a focused task block to get out ahead of the small things on my lists for October. Be sure in this block to finish <specific 20-minute task that is time sensitive>

Prepare a lecture for <my fall class>

End the work day with a 1 – 2 hour writing block.

Today is a research day: head in the office right away to dig into <research project>.

End day with 1.5 hours in <a favorite secluded spot on campus>, where the first hour is writing and the last thirty minutes is a batched attack on tasks.

November

I have a training seminar to attend in the morning and a meeting with my student in the later afternoon. Between these two events focus on prepping another lecture.

Depending on the length of my afternoon meeting, I may be able fit in a task block before coming home.

December

First thing in the morning do budget and take care of <related annoying financial task>. The goal is to finish before <doctor's appointment near where I live>

After the doctor's appointment find a quiet place to work deeply on <research project>.

End day somewhat early for <yard work project>

Write. Deep work on research until mental burn out. Shutdown for weekend. Finish <yard work project>.

The above weekly plan represents the most common format I use: sketching my goals for QUARTER. Notice, I'm not simply listing things I want to get done each Quarter, but instead, I will Review Calendar, Value Plan and Project Tracker, and then decide what I want to Achieve Each Month. A big part of the Quarterly planning process is working backwards from your calendar to fill in the open time effectively.

Example: Quarterly Plan #2

Research

Carve out three hours of deep work every day for the below research tasks. This is the core of each day's schedule.

This week is do or die for getting to a final result for <a research project with an upcoming deadline.>

During downtime on this project (while waiting for responses from co-authors), see if I can push through <the final details of a different proof I'm working on.>

Dedicate one day's deep work for finishing <a journal paper review>

Georgetown Teaching/Misc

Each day, outside of the deep work hours assigned above, make progress on the below non-deep tasks.

Once my new textbook arrives, I need to decide on my syllabus for <class I'm teaching this fall> and post online.

The following small tasks are time sensitive this week: (1) pick up new parking pass; (2) send back visa letter for <a researcher I know>; (3) respond to <a colleague's> recent questions.

Writing

Use the morning block <[note: I sometimes work for an hour at home in the morning to allow traffic to die down]> and commute to plan and gather the sources I need to start writing next week.

Over weekend, write a blog post where I <reminder of post topic>

This plan adopts a different format. Because this was a summer week with no major appointments, meetings, or other scheduled obligations to break up my days (so rare, yet so wonderful), I could base my schedule around some simple heuristics: three hours a day on deep work for research, and a list of small things to schedule each day into the time that remains.

I would never get away with this approach during the height of the school year, but for a lazy week in July, it worked perfectly.

The bigger message here, however, is that I always decide in advance what I am going to do with my week. These decisions look different at different times of year, but what matters is that when it comes to my schedule, I'm in charge.

Rule 12- Add, Write and Mark in Calendar, Every Last Friday, Saturday and Sunday of Each Month, That I will Do Review of the Quarterly Planning. This helps to See If I am on The Track or I need to Do some Changes in My Schedule or Do Something Differently.

Rule 13-Review Every Part of Quarterly Planning, If I am on the Track Every Last Friday, Saturday and Sunday of Each Month, By using All Parts of *Journaling and Review of A Month* Pages 2083-2086

4. Create and Update Weekly Value Plan.

Rule 1- I Need To Review And Analyse Value Documents On Following Date:

- I. Deep Life, Deep Work and Benjamin Franklin Routine Pages 21-22.**
- II. To Create Weekly Value Plan, I Need To Review and Analyse The Quarterly Value Plan Last Friday, Saturday and Sunday Of Week, To Create Next WEEK, Weekly Value Plan.**
- III. It Usually Takes Around 90-180 Minutes.**

Rule 2- To Create Next Weekly Value Plan, I Will Review and Analyse The Following Document:

- I. Identify End Goals. Page 11.**
- II. Quarterly Value Plan.**
- III. Quarterly Value Plan Note Book.**
- IV. For Values Use Values and Code Of Conduct By Which I live Page 5-24.**
- V. For Behaviour and Moral And ethics in Personal Life use values and code of conduct and Skills By Which I live Page 25-38.**
- VI. For Behaviour and Moral And ethics in Professional Life use values and code of conduct and Skills By Which I live Page 39-51.**
- VII. Skills I will Learn For Personal Life and Professional Life. Pages 52-82.**

Rule 3-After Review and Analysis of the Quarterly Value Plan, Quarterly Value Plan Note Book, Value, Code Of Conduct and Skills Documents, I need to Decide The number of Values, Code of Conduct and Skills For Next Week Weekly Value Plan

- I. Between 1-2 Values I want to Practice For This Week.**
- II. Between 1-2 Personal Code Of Conduct, I would Like to Practice For this Week.**
- III. Between 1-2 Professional Code of Conduct, I Would Like to Practice for this Week**
- IV. Between 1-2 Skills, I would like to learn and practice for This Week.**

Rule 4-Write On the Weekly Value Plan Notebook, Decided Values, Professional and Personal Code Of Conduct And Skills I will Pursue and Work For This Week.

Rule 5- Add, Write and Mark in Calendar, Every Last Friday, Saturday and Sunday of Each Week, That I will Do Review The Previous Week Weekly Value Plan This helps to See If I am on The Track or I need to Do some Changes in My Schedule or Do Something Differently.

Rule 6-Review Every Part of Previous Week Weekly Value Plan, If I am on the Track Every Last Friday, Saturday and Sunday of Each Week, By using All Parts of *Journaling and Review of A Week* Pages 2088-2091.

5. Productivity (Weekly and Daily Planning).

Step 1 Create Weekly Planning.

Rule 1- Create Weekly Planning on Friday Saturday and Sunday Or Weekday Begins, on Monday Morning. I deploy weekly Planning. Be flexible with Your Weekly and Daily Planning. Spend Between 90-120 Minutes, on what is upcoming for next week and decide how to tackle. When Planning For Weekly, this planning must have intention.

Rule 2-Review Values Once A week On Weekends to remind myself What are my values and my life for.

Rule 3-Every Weekly Planning is Based on The Following:.

- I. Identify End Goals. Page 11.
- II. Deep Life, Deep Work and Benjamin Franklin Routine Pages 21-35.
- III. Weekly Value Plan Document.
 - **Values I want to Practice for The Week.**
 - **Professional Code of Conduct, I would Like to Practice for The Week.**
 - **Personal Code of Conduct, I would Like To Practice for the Week.**
 - **Skills I would like to learn and practice for the Week.**
- IV. My Strategic Plans (Quarterly Planning).
- V. My Calendar. This Includes Professional, Academic and Personal.
- VI. My Project Tracker.
- VII. My Task Lists.
- VIII. Work Notebook.**
- IX. Work Priorities Word Document And Time Frames For Task.**

X. Daily Planning.

Rule 4- Take Daily Planning Note Book. These are the following Reason, To take Daily Planning Notebook First, while Creating The Weekly Planning Are:

- A.** Once I Know Common things that I need to do on Constantly on daily Basis Without any changes and draw them on the Daily Planning. This helps me to see Visually, the amount of Time available on daily basis. This helps me to see what Tasks, Goals and Workday Activities I could Prioritize in Planning for the Week and Work On Them.

Rule 5- Take Daily Planning Note Book. Draw TimeBlocking On Daily Planning For Next Week Monday To Sunday. This Should Take Between 60-120 Minutes.

- A.** Step 1 Open 2 page Planner.
- B.** Step 2. Draw Square Shutdown Box At The Top Of the Left Page. System, that helps to mind shift from work mode to non work mode.
- C.** Step 3 On the Left Page Draw The vertical Line in The Middle from the top to 7 Lines Down
- D.** Step 4- Around 7 lines from the top Draw Horizontal Line, And Write the Following:
- I.** On Left Side Of Page Write Tasks.
 - II.** On the Right Side of the Page Write Ideas.
- E.** Step 5. Left Page DRAW Two Horizontal Lines between Line 7-14 and Write Metric Tracker.
- F.** Step 6 -On the Left Page Draw The vertical Line in The Middle from The Line 14 to The Bottom.
- G.** Step 7-Discipline of Execution.
- I.** Draw Eisenhower Matrix with 4 Quadrants.
 - Quadrant 1 Do It Right Now-Task Important And Urgent. **Reactive.**
 - Quadrant 2 Schedule It-Task Important But Not Urgent. **PROACTIVE.**
 - Quadrant 3 Delegate It-Task Not Important But Urgent. **Distraction.**

- **Quadrant 4 Delete It**-Task Not Important And Not Urgent. **Time Waste.**

H. Step 8 On the Top Right Page. Write Date.

I. Step 9 On Right Top Page Of Planner, Write Philosophy I Will USE.

J. Step 10 On Right Page Of Planner, Draw 2 Vertical Line on Left Side and Right Side, Making 3 Columns.

K. Step 11 Use 2 Lines To Represent 1 Hour And Write vertically Hours From 6am to 21pm and Divide The Hours of Workday Into 6 Blocks and Draw A Block That Covers Lines Corresponding to these Hours:

- **Early Morning 5am-8am.**
- **Morning 8am-12pm.**
- **Noon 12pm-14pm.**
- **Afternoon 14pm-18pm.**
- **Evening 18pm-22pm.**
- **Night 22pm-05am.**

Rule 6- Think And Write In The TIMEBLOCKING on Daily Planning For Each Day The Common Things That I need To Do Constantly. These Are the Tasks That Needs to Be Done Usually on Daily Basis. Write and Assign Workday Activities to These Blocks And Draw The Box For That Period in The TimeBlock on Daily Planner. Example Of Those Activities Might Be:

A. Early Morning, Listen Deep Life, Deep Work and Benjamin Franklin Routine For Setting Up The Quarterly Value Plan, Quarterly Planning, Weekly Value Plan, Weekly Planning and Daily Planning. This helps to Set Up Tasks, Goals For The day..

- Quarterly Value Plan. Pages 12-13.**
- Quarterly Planning. Pages 14-20.**
- Weekly Value Plan. Pages 21-22.**
- Weekly Planning. Pages 23-35.**
- Daily Planning. Pages 36-53.**

B. Early Morning, Listen Deep Life, Deep Work and Benjamin Routine For Stages 2-12. Pages 67-88 and Stage 14. Pages 107-109. This Helps Me To Prepare My Mind, and Environment For The day and what do I need to Take From Those Stages In order to have Successful Day.

C. Deep Work and Deep Studies. Listen Deep Life, Deep Work and Benjamin Routine. Deep Work and Deep Studies Stages 13. Pages 90-106, Choose What I Need To Do In this Stage. Then Apply Those Things While Doing Deep Work, Or Deep Studies.

D. Powerful Goodness, Bible Study, Devotion, Prayer and Meditate On The Word. Listen Deep Life, Deep Work and Benjamin Routine For Stage 13. Pages 88-104.

E. Employment or Self Employed.

- I. Listen Deep Life, Deep Work and Benjamin Routine Stages 13. Pages 90-106.**
- II. Deep Work.**
- III. Deep Studies.**

IV. Tasks.

V. Emails and Phone.

VI. Meetings.

F. Travel.

G. Bring Children To.

I. Crèche, School and College.

II. Sport and Training.

III. Hobbies.

IV. Work.

V. Other Things.

H. Collect Children From.

I. Crèche, School and College.

II. Sport and Training.

III. Hobbies.

IV. Work.

V. Other Things.

I. Listen and Practice Reflect, Review and Journaling For Today. Rules of Reading Pages 2088-2091.

J. Listen and Practice Discipline- Do Daily No Matter What. This is on Values and Code of conduct and Skills by which I live Page 3.

K. Do Homework, Read, Learn, Sport With Children.

L. Sport I Do on Daily Basis.

M. Gym Time Twice A Week. (Monday or Wednesday and Friday).

N. Family Time.

O. Academic and Self Taught Studies.

P. Put Things in Place and Household Chores.

Q. Any Other Tasks That needs to be done constantly On Daily Basis.

Rule 7- Based on The Professional, Academic and Personal Calendar. Think and Write in The TIMEBLOCKING on Daily Planning, important Task, Activities and Reminders. Write and Assign Workday Activities To Particular Time And Draw A Box For That Period in the TIMEBLOCKING. Example of THIS.

- A. Meeting. Estimate 1.5 times longer than the original meeting. Example. If the meeting is 60 min originally, then schedule 90 Minutes.**
- B. Appointment. Estimate 1.5 times Longer than The original. Example. If the Appointment is 60 min originally, then schedule 90 Minutes.**
- C. Deadline.**
 - I. Academic.**
 - II. Employment.**
 - III. Any other Deadlines.**
- D. Reminder Of Important Date. Like Birthday, Dates Anniversary, National holidays ETC.**

Rule 8-Organise The Task.

- I. When Do I add A task to My List vs Straight Into My Week Plan?**
- II. If the task or obligation pops up, and you writing down and capturing exactly what I need to do. At the End of the day you need to processing the task that needs to be done. There are two places that the task can go:**
 - A. On the Appropriate Task Board List. This is not time specific task list.**
 - B. Or Calendar. It goes on the calendar if this connected to specific day that task needs to be executed. Calendar is for time specific tasks.**

Rule 9- Review And Analyse How Much Time Is Available Based On TimeBlocking on Daily Planning For Each Day. Remember Better To Plan Less and Actually Carry Out. Do not Schedule Too Much on Weekly Planning Basis. Have Realistic Schedule. Use Slow Productivity Approach To Setting Up Goals.

Rule 10 -After Review and Analysis of The Available Time For Each Day of The Week. I will Start to Prepare For Weekly Planning.

Rule 11- Review and Analyse the Following Documents To Plan FOR Weekly Planning:

I. Weekly Value Plan Document.

- **Values I want to Practice for The Week.**
- **Professional Code of Conduct, I would Like to Practice for The Week.**
- **Personal Code of Conduct, I would Like To Practice for the Week.**
- **Skills I Would like to Learn and Practice For this week.**

II. Identify End Goals. Page 11.

III. My Strategic Plans (Quarterly Planning).

IV. My Calendar. This includes Professional, Academic and Personal.

V. My Project Tracker.

VI. My Task Lists.

VII. Work Notebook.

VIII. Work Priorities Word Document.

IX. Daily Planning.

X. What Sport To Do On Daily Basis.

XI. TimeFrame For Tasks.

Rule 12- Once the Review and Analysis of the Documents have been Done. Then Think, Decide and Write What Are The Most Important Goals and Tasks I Will Be Pursuing and Working For this Week.

- I. Based On The Time Available On Time Blocking On Daily Planning, Plan My Week in the Weekly Planning Notebook. Plan My Weekly Deep Work Timetable. This Include lectures, tutorials, your self-study sessions and group study sessions and Any Other Tasks. Enter in the key assignment and exam dates. Work backward from the due date to allocate time needed.**

Rule 13-USE And Apply 80/20 Principle By Asking: Is this Task in the top 20% of my activities or in the bottom 80%? Identify Most Important Task.

- I. Once Identify Task In the Top 20% input that gives 80% of Output. Then, Put 100% effort into 20% inputs, to achieve best results. Remove Trivial Tasks.**

Rule 14-Write Weekly Planning In the Following Format: One Plan with two parts. One Part is for Professional Life and Other Part is Non professional Life.

- I. Step 1- General Principle: Better To Plan Less and Actually Carry Out. Do not Schedule Too Much on Quarterly Basis Have Realistic Schedule. Use Slow Productivity Approach To Setting Up Goals.**

Rule 15-There are Two Ways I will Write the Weekly Plan. Choose One of the Way I will Do it. Embrace whatever format seems most useful for the particular week you are planning.

Rule 16a: Either Plan My Week For Each Day, And What I will Do On that Specific Day Based On Time Available On Time Block On Daily Planning.

Rule 16b. Or I will Plan My Week When, There is No Major Appointments, Meetings or other scheduled obligation that break up my Day, I will Plan based on simple heuristics: like 3 hours of deep work a day and a list of things to schedule each day into the time that remains.

Rule 17: No Matter what Way Will I plan my week, the most important is Always Decide in Advance What I am Going To Do With My Week. These Decisions Look Different at the different time of the year, but what matters is that when it comes to my schedule, I AM IN Charge.

Example: Weekly Plan #1

Monday

After weekly planning do a focused task block to get out ahead of the small things on my lists for the week. Be sure in this block to finish <specific 20-minute task that is time sensitive>

Prepare a lecture for <my fall class>

End the work day with a 1 – 2 hour writing block.

Tuesday

Today is a research day: head in the office right away to dig into <research project>.

End day with 1.5 hours in <a favorite secluded spot on campus>, where the first hour is writing and the last thirty minutes is a batched attack on tasks.

Wednesday

I have a training seminar to attend in the morning and a meeting with my student in the later afternoon. Between these two events focus on prepping another lecture.

Depending on the length of my afternoon meeting, I may be able fit in a task block before coming home.

Thursday

First thing in the morning do budget and take care of <related annoying financial task>. The goal is to finish before <doctor's appointment near where I live>

After the doctor's appointment find a quiet place to work deeply on <research project>.

End day somewhat early for <yard work project>

Friday

Write. Deep work on research until mental burn out. Shutdown for weekend. Finish <yard work project>

The above weekly plan represents the most common format I use: sketching my goals for each day of the week. Notice, I'm not simply listing things I want to get done each day, but instead, I will Review How much time available on each day From Daily Routine, once inserted all the tasks from calendar and The tasks that I am doing Constantly on daily basis. I am trying to Do is match work to the time that actually available on those days. A big part of the weekly planning process is working backwards from your calendar to fill in the open time effectively. Fortunately, because this plan is for a summer week, I had lots of open time to work with.

Example: Weekly Plan #2

Research

Carve out three hours of deep work every day for the below research tasks. This is the core of each day's schedule.

This week is do or die for getting to a final result for <a research project with an upcoming deadline.>

During downtime on this project (while waiting for responses from co-authors), see if I can push through <the final details of a different proof I'm working on.>

Dedicate one day's deep work for finishing <a journal paper review>

Georgetown Teaching/Misc

Each day, outside of the deep work hours assigned above, make progress on the below non-deep tasks.

Once my new textbook arrives, I need to decide on my syllabus for <class I'm teaching this fall> and post online.

The following small tasks are time sensitive this week: (1) pick up new parking pass; (2) send back visa letter for <a researcher I know>; (3) respond to <a colleague's> recent questions.

Writing

Use the morning block <[note: I sometimes work for an hour at home in the morning to allow traffic to die down]> and commute to plan and gather the sources I need to start writing next week.

Over weekend, write a blog post where I <reminder of post topic>

This plan adopts a different format. Because this was a summer week with no major appointments, meetings, or other scheduled obligations to break up my days (so rare, yet so wonderful), I could base my schedule around some simple heuristics: three hours a day on deep work for research, and a list of small things to schedule each day into the time that remains.

I would never get away with this approach during the height of the school year, but for a lazy week in July, it worked perfectly.

The bigger message here, however, is that I always decide in advance what I am going to do with my week. These decisions look different at different times of year, but what matters is that when it comes to my schedule, I'm in charge.

Rule 18- Add, Write and Mark in Calendar, Every Last Friday, Saturday and Sunday of Each Week, That I will Do Review The Previous Week Weekly Planning This helps to See If I am on The Track or I need to Do some Changes in My Schedule or Do Something Differently.

Rule 19-Review Every Part of Previous Week Weekly Planning, If I am on the Track Every Last Friday, Saturday and Sunday of Each Week, By using All Parts of *Journaling and Review of A Week* Pages 2088-2091

Step 2 Create Daily Planning

Rule 1-Define Deep Work and Shallow Work:

- I. Deep Work is ability to focus without distraction on a cognitively demanding task.** This creates new value, improve skills and Hard to Replicate.
- II. Shallow work: Non-cognitively demanding, logistical-style tasks, often performed while distracted and Not Create New Value or Improve Skill.** It is not Deep Work, but Shallow Work if the work is not Hard, Context Shift and or have Distraction.

Rule 2- Create Daily Plan Either At The Shutdown Previous Day or Evening of Previous Day or In the Morning. Be flexible with Your Daily Planning. Spend Between 90-180 Minutes, on what is upcoming for next Day or Today and decide how to tackle. When Planning For Daily, this planning must have intention.

Rule 3-Review and Analyse the Following Documents To Plan FOR Daily Planning:

- I. Identify End Goals. Page 11.**
- II. Deep Life, Deep Work and Benjamin Franklin Routine Pages 36-67.**
- III. Weekly Value Plan Document.**
 - Values I want to Practice for Today.**
 - Professional Code of Conduct, I would Like to Practice for Today.**
 - Personal Code of Conduct, I would Like To Practice for Today.**
 - Skills I Would like to learn and practice for Today.**
- IV. Weekly Planning.**
- V. Project Tracker.**
- VI. Habit Tracker.**
- VII. My Task List.**

VIII. Work Notebook.

IX. Work Priorities Word Document.

X. TimeFrame For Tasks.

XI. What Sport To Do On Daily Basis.

XII. My Calendar.

- Academic.
- Professional.
- Personal.

XIII. If it's a weekday, build a time block plan. If not, sketch a looser plan.

Rule 4- Once the Review and Analysis of the Documents have been Done. Then Think, Decide and Write What Are The Most Important Goals and Tasks I Will Be Pursuing and Working For TODAY.

Rule 5-USE And Apply 80/20 Principle By Asking: Is this Task in the top 20% of my activities or in the bottom 80%? Identify Most Important Task.

- I. Once Identify Task In the Top 20% input that gives 80% of Output. Then, Put 100% effort into 20% inputs, to achieve best results. Remove Trivial Tasks.**

Rule 6-General Principle: Better To Plan Less and Actually Carry Out. Do not Schedule Too Much on Daily Basis. Have Realistic Schedule. Use Slow Productivity Approach To Setting Up Goals.

Rule 7-Each Drew Eisenhower Matrix Have Different Quadrant For Different Tasks And Activities, These are the following Quadrants, and what Activities and Tasks will be Written in Each Quadrant.:

1. Quadrant 1 Do It Right Now-Task Important And Urgent. Reactive.

- **Shallow Work, Meeting, Solitude, Boredom Appointment, Deadlines, Crises, Emergencies, Emails, Phones, Social Interaction, Auditing Time Spend, Meditation, High Quality Downtime, Ad Hoc Tasks.**

2. Quadrant 2 Schedule It-Task Important But Not Urgent. PROACTIVE.

- **Spend Majority of Time In Quadrant 2.**

- **Personal Life.**

- **Values.**
- **Behavior.**
- **Moral Ethics.**
- **Skills.**

- **Professional Life.**

- **Values.**
- **Behavior.**
- **Moral Ethics.**
- **Tasks.**
- **Goals.**
- **Skills.**

- **Goals.**

- **Tasks.**

- **Deep Work and Deep Studies.**

- **Learning and Studies.**

- **Review, Journaling and Visualisation.**

3. Quadrant 3 Delegate It-Task Not Important But Urgent. Distraction.

- **Task not Important For you, But Urgent for Others. Avoid This Quadrant As Much as Possible.**

4. Quadrant 4 Delete It-Task Not Important And Not Urgent. Time Waste.

Rule 8:Example of How Will I Write in Eisenhower Matrix of Any Quadrant.

I. Example.

- Quadrant 1-Deadline.

i. Part 1 Submit Assignment.

a. Task. Check Eisenhower Matrix, What Steps To Take.

Rule 9- Once the Review and Analysis of the Documents have been Done. Then Think, Decide What Are the Moat Important Goals and Tasks I Will Be Pursuing and Working For TODAY.

Rule 10- I Need to Ask Myself For Each Goal, Task and Workday Activities, the Following Questions:

- I. Ask Myself If I need to Use Rules of Reading For Today. If Yes, Then Write In Eisenhower Matrix, The Page OF Rules of Reading That I will Use. Then Listen, Follow and Apply Rules of Reading To The Task, Goal and Workday Activities.**
- II. Ask Myself If I need to Use Feynman Technique For Today's Deep Work Or Any Other Task. If Yes, Then Write In Eisenhower Matrix, The Page OF Rules of Reading That I will Use. Then Listen, Follow and Apply Feynman Technique To Any Deep Work or Task.**
- III. Ask Myself If I Need To Use Newspaper, Internet, Youtube, WhatsApp and Email For Today. If Yes, then Check If those Reasons are based On Rules Of Reading Pages 18-22.**
- IV. Do I need to Use Computer or Phone Today For Any Task, Goal and Workday Activity?**

Rule 11- Ask Myself If the Tasks, Goals or Workday Activities on the Quadrant 2 are Values, Behaviors, Moral Ethics For Professional or Personal, Learning and Studies, Deep Work or Deep Studies or Review and Reflect Journaling.

I. Determine if A Task Qualifies As Deep Work By Asking Questions. If All the Answer is Yes to Most Questions, then it falls under category of Deep Work:

- **Does this task require focused attention?**
- **Does this task require specialised training or knowledge?**
- **Does this task create new value in the world?**
- **Would this task be difficult to replicate?**

Rule 12- Group Eisenhower Quadrant 1 Tasks based on Similarities.

Rule 13-Eat That Frog Means Tackle The Biggest, Hardest and Most Important Task First. Ask Yourself, what is the Biggest, Hardest and most Important Task For Today?

Rule 14-USE And Apply 80/20 Principle In Every Area By Asking: Is this Task in the top 20% of my activities or in the bottom 80%? Identify Most Important Task, Based ON Weekly Planning.

I. Once Identify Task In the Top 20% input that gives 80% Output. Then, Put 100% effort into 20% inputs, to achieve best results. Remove Trivial Tasks.

Rule 15- Ask Myself If the Tasks, Goals or Workday Activities Needs to be Breakdown into Smaller Manageable Tasks?

I. If The answer is Yes, then I need to Write on Piece of Paper the Task, Goal or Workday Activity. Then, I Need to Write what is the First Small Task of this Big Task.

Rule 16- Write AND Fill The Eisenhower Matrix, what are the Tasks, Goals and Workday Activities I have decided to Do. Put Each Task, Goal and Workday Activity In the Appropriate Eisenhower Matrix Quadrant.

Rule 17- Once The Task, Goals and Workday Activities, Have been written in the Appropriate Eisenhower Matrix, Then You need to Do the Following:

- I. Under Big Task, Goal or Workday Activity in the Eisenhower Matrix, Write Down what are Part 1 and Smaller Manageable Tasks, and activities I Will Do It. Under The Smaller Tasks, and Goals, Then Write Letter (A) or Other Letters and then Smallest Manageable Tasks, Must, Need, Should Do it, To Complete the Big Task. This does not mean I will finish up Big Task Today, but those small manageable tasks can help to complete the task in the next few Months, Weeks, Days.**

II. Example of Writing in Eisenhower Matrix Quadrant:

- (Name of Big Task or Goals) Deadline.**
 - i. Part 1 (Name of Smaller Task or Goals) Submit Assignment.**
 - a. (Smallest Manageable Task) Task.**

Rule 18- Decide The Place and The Amount Of Time I will spend on each activity, be realistic and do not UNDERESTIMATE the time, better overestimate the time.

- I. Deep Work: Where, When, How long and How will you work?**
- II. Decide in advance what is The Most Important Task Out of Deep Work That you'll work on during each deep work session Today. To Work Deeply you need to focus on one task and ignore everything else. When you decide what to concentrate on in advance, you can avoid multitasking.**
- III. Determine, How Much Time Do I need To Finish Up This Deep Work, Shallow Work or Any other Task. Block Off The Time For Tasks, and Block Off Large Chunk of Time Every Day For Deep Work.**
- IV. Give Yourself A time Limit for Each Task and Have Defined Clear Metrics of Success. Next to each item on the list, write about how long it'll take you to accomplish each task. Be realistic about this estimate. Then, try to complete each task within the confines of each time limit. Example you might set a goal to write 500 words every 30 minutes—this way, your task is straightforward and you naturally get two simple progress checks per hour. Time blocking helps you to learn how really long does it take for the things to be done.**

Rule 19-Decide What Type of Note Taking Method Will I Use, When Doing Deep Work:

- I. Analytical Learners: Outline/ List. Good Works well for recording terms, definitions, facts and sequences**
- II. Sentence Method: The goal is to jot down your thoughts as quickly as possible. Works well in meetings or lectures that lack organization. Use when information is being presented very quickly.**
- III. SQ3R (Survey, Question, Read, Recite, Review). Use for dense readings (like business books, text books, whitepapers, etc.). You start the process by skimming the material for bolded text, images, diagrams and summaries in order to produce a list of headlines or main topics.**

- IV. Mapping.** Mapping is a nonlinear system of note-taking that resembles a tree and root structure. Ideas stem from one major concept and are connected by lines (or “branches”). As a note-taking system, mapping works particularly well for visual learners, but it can also be a great tool for analytical-thinkers who have trouble brainstorming because it allows you to make connections you’d otherwise miss with a linear format. Works well for planning essays, recording meetings. Use for big-picture brainstorming sessions.
- V. Smart Wisdom.** It’s a tool optimised for active listening in lecture situations. Instead of taking notes in full sentences, you record only keywords and place them in a chain that maps the thought process.
- VI. Diagram And Processes.** Diagrams help visually represent content. However they are not always versatile. A diagram usually serves one purpose best, so selecting the right diagram will make your notes more meaningful.

VII. Cornell Note Taking

- Name.
- Date.
- Class and Period.
- Topic.
- Essential Question at the Top of Page.
- Questions and Main Ideas on the Left Page of the Blank Page.
- Notes On the Right Page of the Blank Page.
- Summary at the bottom of the page.

VIII. Use Smart Notes.

- What is big Idea.
- Question.
- Evidence.
- Conclusion.

IX. Charting. Charting is a great note-taking strategies when you need to compare and contrast ideas. The most widely used charting method is the Pro/Con list.

X. CERC.

- Claim
- Evidence
- Reasoning
- Conclusion

Rule 20 Eat That Frog Means Tackle The Biggest, Hardest and Most Important Task First. Assign This Block of Activities Early in the morning or When I am most effective in the day.

Rule 21 Based on The Decided Tasks, Goals and Workday Activities On the Eisenhower Matrix. Assign Scheduled Activities To Block In The Timeblock, And Draw The Box For That Period in The TimeBlock on Daily Planner. Below is How Will this be Written In the TimeBlock.

I. Example of Writing in the assigned Box.

- **Q-(Write Quadrant from which Task Will be Taken) (Name of Big Task)- Part (Number) and (Smaller Tasks)- A- (Smallest Task. Always be as Letter, In Assigned Box)- Then Check Eisenhower Matrix To See what steps do I need to Take.**
 - i. Example: Q1 Deadline-Part 1-A.
 - ii. Always Check Eisenhower Matrix Quadrant on the Left Page of Daily Planning for That Task and Review What Steps Do I need To Take in Doing This Task.
- **(Write Number in the assigned box), then review on the last Column of the right page of daily planning,] for the list of short Tasks that I need to do. This would be for very short tasks that I need to do it.**
 - i. Example: 1
 - ii. Tasks: (Buy food, pick child, buy coffee, take shower).

Rule 22 Ask Additional Questions when Assigning and Block the periods of time on the Timeblock:

- I. Have I Scheduled time for Distractions, Emails, Internet, Phones. Limit the time you spend on email. If your work requires you to regularly check your email, schedule 1 to 2 hours each day for checking your email; don't look at it during other times.**
- II. Have I set For High Quality Downtime and Recharge?**
 - **Walk.**
 - **Run.**
 - **Read.**
 - **Get New Hobby.**
- III. Set Time for Social Interaction At Work: Do not involve into office politics, but come to do performance. If there is office politics, then you need go and do the job or perform instead involve into office politics.**
- IV. Set Time for Social Interaction With Friends and Other People Outside of Work.**
- V. Set Time For Appointments.**
- VI. Set Time For Meeting. Audit your meetings.**
- VII. Set Time For Boredom and Let Boredom Happen. No Gadgets, Social Media or high Stimulus.**
- VIII. Set Time For Meditation.**
- IX. Set Time For Auditing Time Spent. Audit how you're spending your work time. Before you can trim away shallow work to make room for deeper pursuits, you have to understand the type of work you do on a day-to-day basis. To do this, list out every activity or task you engage in—then quantify the depth of every activity so you know how much time you're spending on deep work vs. shallow work. Reflect on and tweak your schedule: Newport suggests reviewing the accuracy of your time blocks at the end of each day. This will help you set more accurate goals and expectations in the future.**

Rule 23 On the Top Right Page. Write Today's Date.

Rule 24- Analyse Eisenhower Matrix, and Based on That Decide What is the Deep Work and Shallow Work Ratio?

Rule 25 On Right Top Page Of Planner, Based on Eisenhower Matrix and Deep Work and Shallow Work Ratio on the Rule 21, Decide Deep Work Philosophy The Most Appropriate For Today, and Check What is Going to Be Done In Those Blocks On Pages.

I. Shallow Work Philosophy.

II. VAIDAS Daily Routine Philosophy.

III. Benjamin Franklin Daily Routine Philosophy.

IV. Journalistic Philosophy. Journalistic strategy involves do deep work whenever it fits into your schedule. **The Journalistic Philosophy of Deep Work Scheduling is an option for people who are constantly on the move with little to no regularity to their days. This method demands vigilance with your time and the keen ability to notice natural ebbs and flows in your day where you may be able to fit in 30 minutes or an hour or two of deep work. Unfortunately, this method is not for beginners and is likely to fail for people who are not experienced in deep work.**

V. Rhythmic Philosophy. Involves time blocking certain hours, about 1 to 4 hours each day, to complete your deep work tasks. **The Rhythmic Philosophy of Deep Work Scheduling is ideal for individuals with a fairly static schedule. If you can anticipate what most of your days will look like, it's feasible to block off several hours every day for deep work, thereby getting into a daily "rhythm" and leaving the rest of your hours for shallow work.**

VI. Bimodal Philosophy. Involves splitting your schedule based on Deep and Shallow Work. Spend a Day or Week on Deep Work and once is completed, Then Focus on only shallow work. **The Bimodal Philosophy of Deep Work Scheduling allows for a high amount of deep work while enabling you to maintain other activities in your life that you find valuable. Successfully adopting this philosophy requires the flexibility to arrange your year, months, or weeks as you see fit into larger chunks of deep work.**

VII. Monastic Philosophy. Involves cutting out all shallow activities to focus on deep work for weeks or months. Monastic Philosophy **Is the most dedicated form of deep work and involves spending all of your working hours on a singular high-level focus.** While this philosophy has the highest potential for reward and the lowest level of context switching, it's unrealistic for most people who are required to perform various kinds of work in their role. It also blocks the potential for new opportunities, as your default response to commitments that arise is "no."

Rule 26 On Right Page The reason there are three Columns are the following:

- I. If New Obligation comes up, Then on right page, the next Column, reschedule the day.**
- II. To Fix The Time Block, First Cross Out The Time Blocks that Remain In My Current Schedule. Then, In The Next Column To The Right Of Your Current Schedule, Create New Schedule For The Remaining Hours, And Turn Your Attention To Executing New Plan.**
- III. If schedule disrupted, Either create a revised schedule, or Give longer Time than required to handle the tasks.**

Rule 27-On Left Page Organise The Task in the Daily Planning.

- I. When Do I add A task to My List vs Straight Into My Week Plan?**
- II. If the task or obligation pops up, and you writing down and capturing exactly what I need to do. At the End of the day you need to processing the task that needs to be done. There are two places that the task can go:**
 - A. On the Appropriate Task Board List. This is not time specific task list.**
 - B. Or Calendar. It goes on the calendar if this connected to specific day that task needs to be executed. Calendar is for time specific tasks.**
- III. Structure the information that you have captured, whether it is by categories or by role, etc. Your captured information needs an available structure. Availability in this case refers to the possibility to understand what is happening next. Organising your information will allow you to avoid cognitive overloads since you get a "gestalt" of what is going on in your life.**
- IV. Review all Tasks and All information on a regular basis.**

Rule 28-On The Left Page, Write Down Distracting Ideas and General Ideas That Comes During the Day.

- I. One captured the idea on the Daily Planning, then Transfer into the Book of Ideas.**

Rule 29-On The Left Page, What to Write In the Metric Tracker, and What is the Purpose of Metric Tracker.

- I. In This, You Can Track, How Many Hours Do You spend In Deep Work without distraction.**
- II. Any Disciplines I decided To Do On Daily Basis.**
- III. This can be also how many number of sales calls you made today.**
- IV. How Many Steps I made.**
- V. TRACK WHAT you can use the phone for.**
- VI. How Many Minutes I exercised or How many sets of particular exercise I did.**
- VII. Or Some other Metrics That I will follow.**

Rule 30-Ask Yourself, IF I AM Intentional with The Time?

Rule 31 Finish up Job At 17-17:30 and Do not Bring Work To Home.

Rule 32 Did I Ask The Question In The Morning and Evening? This is Based On Values:

- A. What Good Shall I Do This Day?**
- B. What Good Have I Done Today?**

Rule 33 Have Deep Work Timer. If I get up for Bathroom or Coffee, then the Deep Work Timer is stopped, Once Back, Turn On Timer. Deep Work Hours Only counting, when I actually Do Deep Work.

Rule 34 Be There and Do Grinding of Deep Work, even if I Don't feel it.

Rule 35 Use Slow Productivity When Doing Any Task or Deep Work.

- I. Step 1- Slow and Steady and Time Line Expansion. Working Quality of Work again and again in the right setting giving the work the respect and the support it needs to be good. You need to look at this way, did I produced at the end of this year that I am proud of. Best serve is slow, steady and Quality.
- II. Step 2-Do not juggle between task, but do one task at the time at normal and natural pace.
- III. Step 3-Do fewer things daily. You are not a computer processor, you are human.
- IV. Step 4- Work at a natural pace. Seasonality at various level. Instead of worrying about how much you can do in a day, worry how much you can do in months & years? This will shift your perspective.
- V. Step 6- Be obsessed with quality. Do less, do better. Skilled important activities gives you motivation & make you feel more fulfilling.
- VI. Step 7- Be minimalist in your schedule. Say No often on taking more work.

Rule 36-Do At The End of Each Day Review And Reflection of The Progress.

Rule 5- Add, Write and Mark in Calendar, Every Last Friday, Saturday and Sunday of Each Month, That I will Do Review of the Quarterly Value Plan This helps to See If I am on The Track or I need to Do some Changes in My Schedule or Do Something Differently.

Rule 6-Review Every Part of Daily Planning. By using All Parts of *Journaling and Review of A Day* Pages 2088-2091.

Rule 37-Do Shutdown. This is System, that helps to mind shift from work mode to non work mode.

- I. Part 1. Make sure that the personal metrics are recorded.**
- II. Part 2 Go Through task, and Ensure that The Tasks are Fully Captured. Deciding what you want to do with it. You may need to add new task or update calendar.**
- III. Part 3 ideas in the collection column, deciding what you want to do with it. You may need to add new task or update calendar.**
- IV. Part 4 Briefly review any potential sources of unresolved work obligations, by reviewing your calendar and obligation tracking system.**
- V. Part 5 Check weekly plan, and make updating as needed.**
- VI. Part 6 Make The Shutdown Box Completed By Tick the Box On The Top of Left Page of the Daily Planning.**

Shallow Work Philosophy.

5am-8am: Early Morning.

- Rise, Go Outside Get Light, Cold Wash.
- Deep Work: Spiritual or Personal Growth, Learning and What Type of Person I want to Become.
- Journaling And Visualisation.
- Contrive Day's Business and Take Resolution of the Day-Schedule The Day.
 - I. The Question: What Good Shall I do This Day?
- Prosecute the Present Study Or Physical.
- Travel.
- Breakfast.

8am-12pm: Morning.

- Shallow Work, Deadlines, Crises, Emergencies.

12pm-14pm: NOON.

- Shallow Work or Nap.
- Break, Lunch and Intermittent Fasting.
- Financial Security: Read or Look Over Account and Dice.
- Physical

14pm-18pm: Afternoon.

- Shallow Work, Deadlines, Crises, Emergencies.

18pm-22pm: Evening.

- Travel.
- Shallow Work and Put Things In Place.
- Supper.
- Family, Or Social or Health or Physical or Mental or Health or Leisure or Communication or Environment.
- Examination of the Day, Journaling and Visualisation.
 - I. The Question: What Good Have I done Today?
- Prayer.

22pm-5am-NIGHT.

- **Pre-Sleep Ritual and Sleep.**

- Prayer.

22pm-5am-NIGHT.

- Pre-Sleep Ritual and Sleep.

Step 4 Periodic Review.

Rule 1- After establishing your Deep Life Stack, it's important to review and possibly iterate through the layers periodically. Use a specific time, like your birthday, as an anchor for this review. Check if your discipline, values, Professional code of Conduct, Personal Code of Conduct, and plans are still in alignment with your goals and make the necessary adjustments. Do The Deep Life Stack Once A year go through the whole, however on Quarterly, Weekly, Daily Basis review: Values, Calm and Plan.

I Will Read or Listen Like AudioBook On Phone, On Daily Basis And Apply TO The Task, Deep Work, Deep Studies, Learning and Studies.

Stage 2: What Projects Do I Commit

Rule 1: Use Productivity Funnel To Decide What Project Do I commit.

- I. Step 1-Top- Selection. Potential Activities comes. In selection part you trying to figure it out, the activities coming into funnel, which actually I am going to bring it to my system, and how to execute at some point. Lots of activities going to be blocked at this stage.**
- II. Step 2- Middle-Organisation. The activities that I select, needs to be organised. Where they kept track of, where is information associated with the activities kept track of. This is where you use capture system. Quarterly, weekly, Daily Planning.**
 - Goal 1-There are two goals for this funnel level: to avoid forgetting what you're supposed to do. and to make smart decisions about what to work on next.**
 - Goal 2-Make smart decisions about what to work on next.**
- III. Step 3-Bottom- Execution. Now I know what I am supposed to be doing, now I need to know how will I do it. This is where deep work meets shallow work, Scheduling, quarterly, weekly, daily and execute the activities.**

I Will Read or Listen Like AudioBook On Phone, On Daily Basis And Apply TO The Task, Deep Work, Deep Studies, Learning and Studies.

Stage 3: How To Fix My Schedule

- I. Do One Project At The Time.**
- II. Do One Task At The Time and At The Natural Pace and Take Time to Complete. Do everything at one's own pace).**
- III. Do fewer things daily. You are not a computer processor, you are human.**
- IV. Work at a natural pace. Seasonality at various level. Instead of worrying about how much you can do in a day, worry how much you can do in months & years? This will shift your perspective.**
- V. Be obsessed with quality. Do less, do better. Skilled important activities gives you motivation & make you feel more fulfilling.**
- VI. Be minimalist in your schedule. Say No often on taking more work.**
- VII. Cutting back on the number of projects you're working on.**
- VIII. Cutting inefficient habits from your daily schedule.**
- IX. Possibly annoying people by sticking to such a fixed work schedule.**
- X. Serialize projects by working on one major project at a time and moving to another when finished to maximise efficiency.**
- XI. Be clear about when to expect results by making an honest evaluation of when you can get something done by.**
- XII. Turn down projects if you're focusing on too many things and can't get a potential project done in a reasonable time.**
- XIII. Drop projects if they end up taking up too much of your time.**
- XIV. Be unavailable at certain times of the day to focus on meaningful work.**
- XV. Turn regularly occurring work into a habit that's done consistently at a fixed date and time.**
- XVI. Start early on important projects (and, Putting End To procrastination.**

I Will Read or Listen Like AudioBook On Phone, On Daily Basis And Apply TO The Task, Deep Work, Deep Studies, Learning and Studies.

Stage 4: Prepare The Environment, Tools and Eliminate Distractions

Rule 1-Set Up Work and Study Space: Have A dedicated Desk or Study Area Purely for Deep Work, means you always have somewhere to Go.

- I. Step 1-Consider the environment you create. Remove anything that can distract you from your work and isn't relevant to the task.**
- II. Step 2-Clean off your desk to include only the things you need to work on, leaving just a few photos or mementos to help you relax a bit.**
- III. Step 3- Limit your desktop to only the things that are required for what you're immediately working on so that there are no extraneous materials to distract you.**

Rule 2- Prepare The Tool Needed For Deep Work. Prepare Required Documents, Articles, Books or Any Resources For Deep Work and Rules for Deep Work.

- I. Step 1- Download or Print all Reading, References or Listening resources, Kindle and Text To Speech.**
- II. Step 2- Decide in advance what you'll work on during each deep work session. To work deeply you need to focus on one task and ignore everything else.**
- III. Step 3- Determine rules to guide your concentration, like whether you'll use the internet, how many words you'll write every 20 minutes, or where you'll put your phone.**
- IV. Step 4- Have Notebook, Pen, Ruler, Pencils.**
- V. Step 5- Headphone.**
- VI. Step 6- Laptop or Phone. Phone and Laptop Can be Used just for Audiobook.**
- VII. Step 7- Coffee, Tea or Water Bottle.**
- VIII. Step 8- Ask Myself If I am Doing Deep Work Alone or Collaboration. Focusing on "serious work" typically entails working alone for hours.**

Rule 3-Eliminate Distraction:

- I. Step 1- To learn hard things quickly, you must focus intensely without distraction.
- II. Step 2-Identify the biggest Distractions. Eliminate each one of the distraction.
- III. Step 3- Find A Place Alone.
- IV. Step 4- Eliminate Mobile Distraction.
 - A. Uninstalling The Apps that Might Trigger.
 - B. Change Notification Settings for apps and phone.
 - C. Delete Social Media apps.
 - D. Quit Social Media All Together.
 - E. No WI Fi.
 - F. Turn off phone or mute.
 - G. Turn off notification.
- V. Step 5- Schedule Time For Distractions, and Stay only on those schedule time to be Distracted.

Rule 4-After The Deep Work, Deep Studies, Clean up Your Desk, and Put things In their Place, and Do Not Leave Your Desk Dirty or Unclean.

I Will Read or Listen Like AudioBook On Phone, On Daily Basis And Apply TO The Task, Deep Work, Deep Studies, Learning and Studies.

Stage 5:Hack Meetings, Phones and Emails and Other Technologies.

Rule 1- Hack Meetings:

- I. Step 1- Make it Harder To Call a meeting. Require An Agenda and A Brief Document.**
- II. Step 2-The Meeting Margin Method Assume you have to schedule a meeting that lasts X minutes. Instead of blocking off X minutes on your calendar, block off (1.5)*X minutes.**
- III. Step 3-To process the meeting: clarify any new obligations that were discussed and make sure they're in your system. Perhaps execute some of the smaller tasks right away. The goal here is to close all open loops related to the meeting so that it releases its hold on your mental energy moving forward in the day.**
- IV. Step 4- To catch up on anything missed while in the meeting: check your inboxes to handle anything urgent (if you're in the type of job were such urgent communication is common and cannot be ignored). The goal here is to eliminate the need for you to rudely and uncomfortably split your attention during the meeting itself by constantly checking your inbox. If you know you have time right after to check in, you can confidently concentrate while in the meeting.**
- V. Step 6-To make progress on real work: if the margin is large enough, make progress on things you know need to get done. The goal here is to stave off that feeling that everyone *but you* has control over your time and attention.**
- VI. Step 7- If You Are in the Meeting be Fully Present.**

Rule 2- Hack Phones:

- I. Step 1- Use Phone For Text.**
- II. Step 2- Use Phone For Calls.**
- III. Step 3- Use Phone for Photos.**
- IV. Step 4- Use Phone For Maps.**
- V. Step 5- Use Phone For AudioBooks.**
- VI. Strp 6- Use Phone For Recording Notes, Ideas, Journaling and Review.**
- VII. Step 7- Uninstall Distracting Apps, Like Social media.**
- VIII. Step 8- Set a Schedule For Online Activities at the Computer.**
- IX. Step 9- Use Digital Minimalism for The Phones and any other Technology.**
- X. Step 10- When You are Doing Deep Work or Having Family Time, Leave the Phone In the Other Room and Do Not Touch.**
- XI. Step 11- Schedule Time For Phones, and Stay only on those schedule time to use Phone.**
- XII. Step 12- When you at home do not carry phone in pocket, but put in one of the rooms. If someone call, text go to that room. You will be less distracted.**

Rule 3- Hack Emails:

- I. Step 1- Change the Email Set up.**
- II. Step 2- Never Schedule A Call or meeting Using Email. Use Microsoft Outlook to set up a meeting in the calendar.**
- III. Step 3-Immediately move obligations out of your inbox and into role-specific repositories.**
- IV. Step 4- Make Senders Do More Work When They Email You.**
 - A. Make senders work for your email addresses; don't list it publicly or have it on your website.**
 - B. Ask senders to filter themselves by having different emails or separate contact forms for different queries.**
- V. Step 5-Do More When You Send or Respond to Emails**
 - A. Reduce the back-and-forth of emails with a "process-centric approach to email." By sending more thorough and complete correspondence, you'll close the loop on a conversation more quickly. Reduce the back-and-forth of emails with a "process-centric approach to email." By sending more thorough and complete correspondence, you'll close the loop on a conversation more quickly. For example, a bad reply would be, "Yes, let's meet for lunch. When works for you?" A better reply is, "Here are times over the next week when I'm available. If any of these work for you, let me know, and please send a calendar invite. If none of these work, please send over a few times that do."**
 - B. Example**
 - If the person wants to meet with you. Answer I would love to meet over hangout. Advise what hours and days are you available. "I'm available, Mon, Wed, Fri from 12pm-3 pm. If you are free at any of those times, send a calendar invite my way and we will talk then.**
 - If does not work for you, give me a quick call at and we can work out a time over the phone.**

VI. Step 6-Don't Respond.

- A. Not every email that lands in your inbox requires a response. For some, the default line of thinking is that “it’s the sender’s responsibility to convince the receiver that a reply is worthwhile”. However, this is a controversial belief. Some suggest that [not responding to emails is rude](#), and others recommend [never responding to your emails at all](#).
- B. These three rules may help you find a middle ground that saves your sanity while still remaining open to opportunities that may arise. Newport recommends that you don’t respond to a message with these qualities:
- It’s ambiguous or otherwise makes it hard for you to generate a reasonable response.
 - It’s not a question or proposal that interests you.
 - Nothing really good would happen if you did respond, and nothing really bad would happen if you didn’t.

VII. Step 7-Hold office hours. Setup a recurring Zoom meeting for set times every week where you guarantee to be present. As much as possible, when people send you an ambiguous request or initiate a conversation that will require a lot of back and forth, point them toward your office hours schedule and tell them to stop by next time they can to discuss. It’s a simple idea, but it can reduce the number of attention-snagging back-and-forth electronic messages in your professional life by an order of magnitude.

VIII. Step 8-Do More When You Send or Respond to Emails. Let your team know when you’re available. Share your communication preferences with your team and let them know when you typically answer messages.

IX. Step 9- Schedule Time For Emails, and Stay only on those schedule time to Check The Emails.

Rule 4- Hack Whatapp and Other Technologies

- I. Step 1- Schedule Time For Whatapp and Other Technologies, and Stay only on those schedule time to Check Whatapp and Use Other Technologies.**

I Will Read or Listen Like AudioBook On Phone, On Daily Basis And Apply TO The Task, Deep Work, Deep Studies, Learning and Studies.

Stage 6: Understand Importance Of Slow Productivity And Apply Slow Productivity In My Life.

Rule 1- Slow Productivity is shift the amount of meaningful things done in the next years. Try to do lot less, but the things I am doing on larger time scale, you get sense overload. Example: you want to produce good book in the next 2 years, this is different type of initiative than trying to do as many writerly promotion things as many as possible.

Rule 2-Slow and Steady and Time Line Expansion. Working Quality of Work again and again in the right setting giving the work the respect and the support it needs to be good. You need to look at this way, did I produced at the end of this year that I am proud of. Best serve is slow, steady and Quality.

Rule 3- Do not juggle between task, but do one task at the time at normal and natural pace.

Rule 4- Do fewer things daily. But You Should Do Most Important Things. You are not a computer processor, you are human.

Rule 5- Work at a natural pace. Seasonality at various level. Instead of worrying about how much you can do in a day, worry how much you can do in months & years? This will shift your perspective.

Rule 6- Be obsessed with quality. Do less, do better. Skilled important activities gives you motivation & make you feel more fulfilling.

Rule 7- Be minimalist in your schedule. Say No often on taking more work.

Rule 8- Work Smart And Hard.

Rule 9-Constrain- We need to be careful to what we saying YES and what we saying No To. Have Rules, how I am going to Decide what I am letting on my plate and what is not.

Rule 10-General Maxim: More Haste, less speed. One should take one's time with everything (do everything at one's own pace). If a decision is to be announces in a letter, better to give preliminary answer (to be polite). Decide and acting are two different things. Slow productivity commitment- do not procrastinate and put things off, but do it slowly consistently and steady.

Rule 11-Mastering one topic at the time and no more than that.

Rule 12- Regardless of What you Get paid per Hour, Give your best. Effort + Attitude Matters. Anywhere you work, you need to work your tail off. No matter how much you paid me, I will work my tail off. This creates the reputation about you that you putting your best no matter how much you getting paid. This shows your great attitude, this will bring more opportunities in your life. Pay Attention to Your effort pay attention to your attitude.

I Will Read or Listen Like AudioBook On Phone, On Daily Basis And Apply TO The Task, Deep Work, Deep Studies, Learning and Studies.

Stage 7: How To Attack Large Project.

Rule 1: Work On One Project At The Time, And No More Than That. This is the Most Important Rule.

Rule 2: Reduce from a project to a reasonable task.

- I. Step 1 Extract Some Reasonable Task That Will Simply Move You Closer to The Full Project Goal. Reasonable in this instance, means that you have what you need to get started, and the whole task shouldn't take more than 1 to 4 weeks to complete.**

Rule 3: Construct a habit-based plan.

- I. Step 1 Figure out when and where you're going to work on your task and what you are going to accomplish. Try to find a place and time you can hit consistently – something you can transform into a habit before your excitement for the project wanes.**

Rule 4: Complete and repeat.

- I. Step 1 At this point, it's time to repeat. You are now closer to completing your project than before. Survey your options and come up with a new reasonable task that will bring you even closer to your goal. Once your new task has been selected, come up with a new habit-based plan, and get back to work. Your path toward project completion will proceed along these lines. One small task, efficiently executed, at a time, until, eventually, you get within striking distance of your goal, and make that final sprint.**

Rule 5: Consistency

- I. Step 1 The big “doers” in life tend to be those who are consistently working, piece by piece, On one Project At The Time. They get it done. Not in a week of caffeine-fueled frenzy, but in a half-year of small, frequent steps forward.**

I Will Read or Listen Like AudioBook On Phone, On Daily Basis And Apply TO The Task, Deep Work, Deep Studies, Learning and Studies.

**Stage 8: Understand The Reward Is Waiting For Me For
Doing Deep Work.**

Rule 1: Consider What Reward Can I get for Finish Up Project or Deep Work.

Rule 2: Reward once You have to Finish Up The Work Or Project.

I Will Read or Listen Like AudioBook On Phone, On Daily Basis And Apply TO The Task, Deep Work, Deep Studies, Learning and Studies.

Stage 9: Preparation Of The Task.

Rule 1-Preparation: Decide in advance what you'll work on during each deep work session. To work deeply you need to focus on one task and ignore everything else. When you decide what to concentrate on in advance, you can avoid multitasking.

- I. Step 1-Think about the tasks that you need to complete and note what time you plan to complete them. Newport recommends breaking down your tasks into half-hour blocks, making sure to schedule buffer blocks to handle emergencies or tasks that run over their allotted time.**

Rule 2-Give Yourself A time Limit for Each Task and Have Defined Clear Metrics of Success. For example, Newport suggests leading metrics like the number of pages you've written or the number of new ideas you've generated. Next to each item on the list, write about how long it'll take you to accomplish each task. Be realistic about this estimate. Then, try to complete each task within the confines of each time limit. Example you might set a goal to write 500 words every 30 minutes—this way, your task is straightforward and you naturally get two simple progress checks per hour.

Rule 3- To learn hard things quickly, you must focus intensely without distraction.”To produce at your peak level you need to work for extended periods with full concentration on a single task free from distraction.”In order to produce the absolute best stuff you're capable of, you need to commit to deep work.

Rule 4- Doing Hard Things:

- I. Step 1-Make better Goals: Goals shouldn't be way too long term. Instead make Goals that you can track, control & those which give you a clear course of action for tomorrow.**
- II. Step 2- Learn how you work: Learn how you get yourself to do that work. Also associate it with Rituals(schedule), environment.**
- III. Step 3- Break it down: Break Big goals into manageable ones by making a rough Roadmap.**

***f*I Will Read or Listen Like AudioBook On Phone, On Daily Basis And Apply TO The Task, Deep Work, Deep Studies, Learning and Studies.**

Stage 10:Remind and Understand Law Of Productivity For Deep Work.

**Rule 1- Understand Law of Productivity for Deep Work and How Do I have To Approach to Deep Work, Studies, Learning, Thinking and Writing on Daily basis:
High Quality Work Produced = (Time Spent) x (Intensity of Focus).**

- I. Step 1-Do Not Seek Instant Gratification or enjoyment of Deep Work. But Apply Compound Effect, as you taking small steps consistently, which overtime leads to radical difference in your Deep Work and Focus.**
- II. Step 2- Deep Work and Focus Make it Habit. As It takes time Deep Work and Focus to become habit. The Habits become Routine, which is something you do every day without fail.**
- III. Step 3- Concentrate on What Is Important and One Task at the time. Never Multitask. Dedicate your full attention to the task. No Multitasking is allowed.**
- IV. Step 4- Consistency is the most important habit.**
- V. Step 5-DON'T WAIT FOR MOODS- show up, whether you feel inspired or not. Do Deep Work and Be There and Do Grinding of Deep Work, even if I Don't feel it On daily Basis.**
 - A. Remind Yourself that I choose The difficult thing to do for Good reasons. You need to feel like you choose the difficult Thing To Do, as you are autonomous author, as what it is you study, or work. The Work is going to be hard, but you understand that this would lead to greater things and opportunities.**

- VI. Step 6-Remind yourself of what you're working towards. Having a goal in mind will give you motivation to finish your work, and you'll be more successful at staying focused.**
- VII. Step 7- Say NO-We need to learn the slow 'yes' and the quick 'no.' Simply being aware of what is being sold allows us to be more deliberate in deciding whether we want to buy it."**
- VIII. Step 8-Don't fall for Work Smart: Do not fall for the work smart only concept. You need to work very hard.**
- IX. Step 9- Practice: Practice if you are playing in the game, so when the moment comes in the game, its not new to me. That's the reason why you practice, thats the effort, so when you get to that moment, you do not have to think, instinctively things happen.**
- X. Step 10-Preparation: Do Proper Planning A Month, Week, Few days and night before which helps to prevent poor performance. The most prepared wins.**
- XI. Step 11-Do More: Stay back and do more work, and put effort to achieve the results I want. If the person makes 100 calls a day, you need to do 200 calls a day. If the person sells 20 products, you sell 40 products. If somebody practices 3 hours, then you do 5 hours. Do A little bit more.**
- XII. Step 12-Make One Move at A Time:You have to put one foot in front of the other. Focus on the day task. You have to have a plan in place, how you going to improve for each day to get better and stick it to the plan and trust the plan, that this brings to the end result.**
- XIII. Step 13-The market rewards people who outwork and out improve. Outwork Everyone: Try to prove that I was better then anybody else in the craft. Wake Up Early and Go To Bed Early. Get the competitive advantage by Waking up early and do the work.**

XIV.Step 14- Regardless of What you Get paid per Hour, Give your best. Effort + Attitude Matters. Anywhere you work, you need to work your tail off. No matter how much you paid me, I will work my tail off. This creates the reputation about you that you putting your best no matter how much you getting paid. This shows your great attitude, this will bring more opportunities in your life. Pay Attention to Your effort pay attention to your attitude.

XV.Step 15- Rationality. Taking an objective view of problems is valuable when you're [dealing with difficult people](#), or defusing situations where [people are angry](#). Instead of being drawn into a shouting match, a Stoic will seek a rational way to resolve the problem.

XVI.Step 16-Calmness. Staying cool and collected is seen as a characteristic of Stoics. By ignoring things they can't control, Stoics are able to focus on the things they can affect. This helps to relieve the stress that's associated with [working under pressure](#).

XVII.Step 17-Strength. Stoics are often able to demonstrate a strong, [resilient](#) attitude to work. Thinking like a Stoic won't make you immune to the demands of a heavy workload or a hectic working environment, but it will help you to recognize the stressors, and reduce their impact.

XVIII.Step 18-Flexibility. By seeking solutions to problems, and continually reflecting on their experiences, Stoics benefit from being able to [work flexibly](#). In turn, this helps them to respond to change, quickly and positively.

XIX.Step 19-Morality. Modern versions of Stoicism also emphasize the moral elements of the philosophy. Sticking up for what's right, and staying true to your values, are key steps toward achieving [ethical leadership](#).

XX.Step 20-Honesty. The self-scrutiny of Stoic meditation can help you to see what genuinely motivates you – and to communicate that motivation to others. In workplaces with a culture of [intrinsic motivation](#), that can be a particularly valuable skill.

XXI.Step 21-Understanding. Bringing reason to bear on your own behavior and motivations can also make it easier to understand other people's actions and emotions. This can help you to [empathize](#) with them, and to build better relationships as a result.

XXII.Step 22- Be tolerant with others and strict with yourself.” – Marcus Aurelius. It seems like a generic saying you’d see on a cheap mug, but to the Stoics, it’s a way of life: you can only control what you can control, and don’t sweat what you can’t prevent. And while experiencing pleasure and pain is a part of life, Stoics say these moods shouldn’t dominate your existence. While there will be moments of happiness and moments of sadness, those shouldn’t be the moments you’re living for. The only thing you can control, the Stoics say, is yourself, meaning [how you react](#) to the situation around you.

XXIII.Step 23- “Waste no more time arguing what a good man should be. Be one.” – Marcus Aurelius. Another meeting filled with talking about talking, another team huddle where you feel like you’re thinking about thinking – are you really doing your work, or just working around your work? Stoics would hate modern business culture that demands the use of jargon, unnecessarily complicated measures for accomplishing tasks, and dozens of meetings where nothing gets accomplished. And if you’re also tired of this old dynamic, refresh things yourself by streamlining your own processes and focusing on what actually matters in your job. What are your values and goals? What do you hope to tangibly achieve this week, this month, or this year? Set an example for your team and cut the fat to start working smart rather than working hard.

XXIV.Step 24-“Approach each task as if it is your last, giving up every distraction, emotional subversion of reason, and all drama, vanity, and complaint over your fair share.” – Marcus Aurelius. Stoic advice for completing tasks is to focus on one thing at a time until it’s done, which is definitely some advice that many could learn from in the technology era. While multitasking might seem like it makes things go faster, it really doesn’t, and it just crowds your mind with a thousand different thoughts. By “drama,” “vanity,” and “complaint,” Aurelius generally means that you shouldn’t dwell on how hard it is to focus. Just try it, and if you fail, that’s totally fine – the next quote has advice for that too.

XXV.Step 25- Repeat, Repeat, Repeat, Repeat, Repeat. Repeating is the Mother of All things. This helps to remember, once you constantly repeating and do it on daily or Weekly Basis.

I Will Read or Listen Like AudioBook On Phone, On Daily Basis And Apply TO The Task, Deep Work, Deep Studies, Learning and Studies.

Stage 11: Pre Deep Work Routine

- 1. Rule 1- Set Up Pre Study Routine: Have you ever watched an athlete or sportsperson prepare for an event? They tend to have a set routine. Stretch in a certain way and a certain order, put their socks on at a certain moment, say a small prayer, talk to themselves with their eyes closed.**
- 2. Rule 2-Do The Focus Training on Daily Basis. Train Your Focus Before Doing Deep Work, Do The Training On Daily Basis In The Morning:**
 - I. Step 1-Training for Focus: Put Away Phone for 2-10 minutes. Sit Down and Pick a point on the object or wall, ideally an object should be the same distance placed to which you going to that work and stare at it, you are allowed to blink, and just try and relax, while maintaining visual focus for 2-5 minutes on the Object. As Your mind Starts to Drift, every once in a while, the mind understands that there is something you need to do, and you do not want to do it, or you can't focus, you will find is it's incredibly boring and agitating, like most things you need to focus on, and having hard time focusing on. What you will find is that it carries over to a really terrific ability to Read, Study, Listen and Deep Work. And You start to notice those internal signals. There is something you need to do, and you do not want to do it, or you can't Focus. Chances are You just have not really taught your brain, how to focus. So Start with your visual focus, and then let your mental focus follow that. After doing this Focus Training for 2 to 5 Minutes, then move into the work that you are about to do and really encourage yourself to do that.**
 - II. Step 2-Practice memorising a deck of cards.**
 - III. Step 3-Learn a song or poem by hard.**
 - IV. Step 4-Commit a list of words in a foreign language to memory.**
 - V. Step 5- Memorize the order of a stack of books.**

I Will Read or Listen Like AudioBook On Phone, On Daily Basis And Apply TO The Task, Deep Work, Deep Studies, Learning and Studies.

Stage 12: Understand About Focus and Hard Focus.

1. Rule 1-Focus — the ability to concentrate all your limited talents on whatever's critical at the moment. Without that you can't accomplish anything of value.
2. Rule 2-Fortunately [sustaining focus for a long period of time] can be acquired and sharpened through training. His suggestion is to “sit down every day at your desk and train yourself to focus on one point.” To Marukami, training to write for four to five hours each morning was no different than training for the marathon that he's run every year for the past two decades. To me, this student is like Murakami's untrained novelist. School work, like any work that requires demanding thinking, is tiring. After a grace period of maybe 20 – 30 minutes, your mind starts to disengage. In [the red book](#), I compare the sensation to a weight descending inside your skull. Your energy fades and you begin to experience a desperate craving for novel stimulation. Nothing in the world seems more tempting than to go seek such stimulation — to check your e-mail, or sift through your Facebook feed like a hyper-extroverted gold prospector.
3. Rule 3-To succeed as a student (or a novelist) you have to fight that feeling and keep working. I call this ability *hard focus*. Fortunately, as Marukami explained, this deficiency can be remedied in the same way that a runner builds his endurance: you have to try to push yourself, each day, a little farther than is comfortable. Over time, your threshold raises. Systematically increased the amount of time I would force myself to work continuously without a break to seek unrelated stimulation. This culminated in my current schedule in which I write for 2 – 3 hours, take a break for lunch, e-mail, and exercise, and then work on my thesis for 2 – 3 hours, before finishing for the day.

I Will Read or Listen Like AudioBook On Phone, On Daily Basis And Apply TO The Task, Deep Work, Deep Studies, Learning and Studies.

Stage 13: Being Focus and Doing Deep and Hard Work.

1. Rule 0- Use Steps in Choosing Topic and Learning From Rules of Reading

VI. Step 1: Part 2: Steps In Choosing Topic, Skimming The Books, Articles Debate, Discussion For Deep Work Or Deep Study Or Bible Study.

- A. Step 5-How To Become Polymath. Page 25.**
- B. Step 6-Choose The Topic. Pages 26-35.**
- C. Step 7-Three Questions to Ask Yourself Before Saying YES to a New Commitment. Pages 36.**
- D. Step 8-What Tools I Will Use For Learning? Page 37.**
- E. Step 9-Narrow Down Subject or Topic. Pages 38-39.**
- F. Step 10-Information Overload: Why we're facing it and how to handle it. Pages 40-41.**
- G. Step 11-Compile Resources And Create Curriculum. Page 42.**
- H. Step 12-Filter Resources. Pages 43.**
- I. Step 13-Choose A Book, Article, Talk, Discussion, Debate, Speeches, Research, Newspaper, Journal And Give The Reason of The Choice. Pages 44-46.**
- J. Step 14 Skimming: Intelligently Skimming Through The Book or Text. VERY FAST READING AND SKIMMING Pages 47-51.**
- K. Step 15- Find Out What Kind of Resource is this? Pages 52-53.**

VII. Step 2: Part 28: Learning and Create Learning Curriculum.

- A. Step 191-Books For Studies. Pages 2123-2124.**
- B. Step 192-Classical Education Curriculum. Page 2125-2127.**
- C. Step 193- UltraLearning Pages 2128-2247.**
- D. Step 194- How To Be Straight A Student. Pages 2248-2320.**

- 2. Rule 1-Deep Work is ability to focus without distraction on a cognitively demanding task.** You Giving Your full attention. Without Distraction Piece is the most important part, and this means no Context Shifting, No Multitasking. Example When I am reading a book, I am not going to open my Email Box to glance every now and then. This creates new value, improve skills and Hard to Replicate. If there is distraction, this is not deep work, if not hard, then this is not deep work.

- I. No Context Shift At all While Performing Deep Work.**
- II. No Glancing.**
- III. No multitasking.**
- IV. No Distraction.**

3. Rule 2- Deep Work Timer

- I. Step 1-Have Deep Work Timer. If I get up for Bathroom or Coffee, then the Deep Work Timer is stoped, Once Back, Turn On Timer. Deep Work Hours Only counting, when I actually Do Deep Work.**

4. Rule 3- Study Time or Deep Work.

- I. Step 1-Our bodies follow what are known as ultradian rhythms-ninety-minutes periods at the end of which we reach the limits of our capacity to work at highest level.**

- II. Step 2- Study Or Deep Work intervals Maximum 45-90 Minutes.**

- III. Step 3- Take Break 5-10 Minutes To Do:**

- A. Coffee.**
- B. Walk Around.**
- C. No Phones.**
- D. Do the Training for your legs.**
- E. Do the training for Eyes.**

- IV. Step 4-Big Break 1-2h.**

- A. Take 20 Minutes Nap within 4 Hours, after Triggering Learning, they learn much faster, In other words the brain rewires much faster.**

- V. Step 5- Spend in Deep Work Between 1-14h a Day.**

5. Rule 4- Take Notes By Using One Of The Following Methods:

I. Use Cornell Note Taking.

- A. Name.**
- B. Date.**
- C. Class and Period.**
- D. Topic.**
- E. Essential Question at the Top of Page.**
- F. Questions and Main Ideas on the Left Page of the Blank Page.**
- G. Notes On the Right Page of the Blank Page.**
- H. Summary at the bottom of the page.**

II. Analytical Learners: Outline/ List. Good Works well for recording terms, definitions, facts and sequences.

III. Sentence Method: The goal is to jot down your thoughts as quickly as possible. Works well in meetings or lectures that lack organization. Use when information is being presented very quickly.

IV. SQ3R (Survey, Question, Read, Recite, Review). Use for dense readings (like business books, text books, whitepapers, etc.). You start the process by skimming the material for bolded text, images, diagrams and summaries in order to produce a list of headlines or main topics.

V. Mapping. Mapping is a nonlinear system of note-taking that resembles a tree and root structure. Ideas stem from one major concept and are connected by lines (or “branches”). As a note-taking system, mapping works particularly well for visual learners, but it can also be a great tool for analytical-thinkers who have trouble brainstorming because it allows you to make connections you’d otherwise miss with a linear format. Works well for planning essays, recording meetings. Use for big-picture brainstorming sessions.

VI. Smart Wisdom. It’s a tool optimised for active listening in lecture situations. Instead of taking notes in full sentences, you record only keywords and place them in a chain that maps the thought process.

VII. Diagram And Processes. Diagrams help visually represent content. However they are not always versatile. A diagram usually serves one purpose best, so selecting the right diagram will make your notes more meaningful.

VIII. Diagram And Processes. Diagrams help visually represent content. However they are not always versatile. A diagram usually serves one purpose best, so selecting the right diagram will make your notes more meaningful.

IX. Charting. Charting is a great note-taking strategies when you need to compare and contrast ideas. The most widely used charting method is the Pro and Con list.

X. CERC.

- A. Claim.
- B. Evidence.
- C. Reasoning.
- D. Conclusion.

XI. Use Smart Notes.

- A. What is big Idea.
- B. Question.
- C. Evidence.
- D. Conclusion.

- 6. Rule 5-To “do less” is to slow down. Focus on one activity at a time. Do less total activities. Be willing to pass through occasional interludes of full non-productivity.**
- 7. Rule 6- Tools Will Be Used For Focus, Pay Attention and Concentration For Any Deep Work, Studies, Learning, Thinking and Writing.**
 - I. Step 1-Use, Listen, Follow and Apply Every Steps of Feynman Technique. Step 161-Feynman Technique. Pages 2021-2033.**
 - II. Step 2- Use Rules of Reading**
 - A. Skimming:**
 - **Step 14-Intelligently Skimming Through The Book. Pages 47-51.**
 - B. Entertainment**
 - **Method 1-Speed Reading. Pages 59-64.**
 - C. Methods for Basic Knowledge For Deep Work or Bible Study.**
 - **Method 1-Survey, Question, Read, Recite, Record, Reflect (SQR4). Pages 66-67.**
 - **Method 2-Use 80/20 Principle For Reading. Pages 68.**
 - **Method 3-Preview, Question, Read, Summary,Test (PQRST). Page 69.**
 - **Method 4-Flip Through Pages and Analyse. Page 70.**
 - **Method 5-Devotional Bible Study by Using Devotional Books. Pages 71-72.**
 - **Method 6-Devotional Bible Read. Pages 73-74.**

D. Deep Work, Deep Study, Bible Study or Any Book- SLOW Reading- Complex Text.

- **Method 1-Chapter Summary Method. Pages 143-147.**
- **Method 2-Character Quality Method. Pages 148-160.**
- **Method 3-Thematic Method. Pages 161-163.**
- **Method 4-Biographical Method. Pages 164-176.**
- **Method 5-Topical Method. Pages 177-180.**
- **Method 6-Word Study Method. Pages 181-189.**
- **Method 7-Book Background Method. Pages 190-194.**
- **Method 8-Book Survey Method. Pages 195-205.**
- **Method 9-Chapter Analysis Method. Pages 206-215.**
- **Method 10-Paragraph Study. Pages 216-229.**
- **Method 11-Verse by Verse Analysis Method. Pages 230-234.**
- **Method 12-Book Synthesis Method. Pages 235-238.**
- **Method 13-Theological Study Method of Bible Study. Pages 239-245.**
- **Method 14-Studying Bible Prophecy. Pages 246-259.**
- **Method 15-Typological Study Method. Pages 260-262.**
- **Method 16- John MacArthur Way Bible Study. Pages 263-268.**
- **Method 17-Inductive Bible Study Method. Pages 269-296.**
- **Method 18-BIBLICAL HERMENEUTICS. Pages 297-302.**
- **Method 19-Theological Group of Principles. Pages 303-306.**
- **Method 20- How To Read A Book Pages 307.**

E. Deep Work, Shallow Work, Bible Study, Analysis of Text, Research, Investigative Journalism, Investigation and Syntopicon, Mixed Method.

- **Method 21- How To Read A Book By Mortimer Adler Various edition Pages 341.**
- **Method 22-How To Read A Book For Various Books. Pages 342-600.**
- **Method 23- Syntopicon Pages 601-642.**
- **Method 24-The Craft of Research. Pages 644-882.**
- **Method 25-Research Books can Be Used. Pages 883-897.**
- **Method 26-Investigative Journalism. Pages 898-923.**
- **Method 27-Mixed Methods of Rules of Reading. Pages 924-942.**

F. Part 6: Analysis Of Book By Using External Sources.

- **Step 40-Aids To Reading, Listening, Conversation, Debate. Pages 944-957.**
- **Step 41-Commentaries On Book and What Are Other's Take on? Pages 958.**
- **Step 42-Review Of The Book. Pages 959-962.**
- **Step 43-Analysing Author and Publisher and Audience. Pages 963-966.**
- **Step 44-How To Spot Bad Science. Pages 967-977.**
- **Step 45-Content Of Critical Review. Pages 978-979.**
- **Step 46-The Funding of Book, Author, Publisher, Speaker, Presenter, School, Government, Politician, Companies, Influencer, Newspaper, Journalist or Other Person. Pages 980-1017.**
- **Step 47-Was There Propaganda and Conspiracy Theories In the Book and Propaganda Analysis. Pages 1018-1025.**
- **Step 48-What did I take From the Book. Pages 1026-1031.**
- **Step 49-Implication of The Book. Pages 1032.**
- **Step 50-My Arguments For Or Against The Author, Writer, Speaker, Debater. Pages 1033-1035.**
- **Step 51-Improve My Arguments and I would Have Another Chance, how would I Approach. Pages 1036-1037.**

- **Step 52-Basic Exploration, Experimentation and Practice. Pages 1038.**
- **Step 54-Simplify The Topic For Myself First. Pages 1055.**
- **Step 55-Reflect, Refine And Simplify. Pages 1056.**
- **Step 56-Return to the source material if you get stuck. Go back to whatever you're learning from – a book, lecture notes, Journal, Newspaper, podcast or any other resource and source – and fill the gaps in your knowledge. Pages 1057-1059.**

G. Part 8: Simplify Explanation and Creating Analogies.

- **Step 70-Simplify your explanations and create analogies. Streamline your notes and explanation, further clarifying the topic until it seems obvious. Additionally, think of analogies that feel intuitive. Pages 1314.**

H. Part 9:Reflect, Refine and Simplify.

- **Step 71-Reflect, Refine, and Simplify. Page 1316.**

I. Part 10:Organise And Review.

- **Step 72-Organise And Review. Pages 1318.**

J. Part 11:Deep Work and Application.

- **Step 73- The Focus to Say No. Pages 1320.**
- **Step 74-Half Life.The Decay of Knowledge and What to Do About It. Pages 1321-1329.**
- **Step 75-Power of I do not know. Pages 1330.**
- **Step 76-Application. Pages 1331-1339.**
- **Step 77-Letting The World Do The Work For You. Pages 1340-1346.**

III. Step 3- Do And Practice Thinking, Logic and Mental Model For Deep Work, Studying, Learning and Personal Growth.

A. Part 7: Thinking, Logic and Mental Model For Deep Work or Deep Study, Or Bible Study

- **Step 57- Slow Down. Pages 1061-1063.**
- **Step 58- NOT MULTITASK. Pages 1064.**
- **Step 59-You Have Required To Do The Work For Thinking and Applying Mental Tool Models. Pages 1065-1080.**
- **Step 60-Why Critical Thinking, Logic, Thinking and Mental Tools Are Important? Pages 1081-1083.**
- **Step 61-Intradisciplinary Thinking. Pages 1084-1125.**
- **Step 62-Multidisciplinary Thinking. Pages 1126-1168.**
- **Step 63-CrossDisciplinary Thinking. Pages 1169-1211.**
- **Step 64-Interdisciplinary Thinking. Pages 1212-1254.**
- **Step 65-Transdisciplinary Thinking. Pages 1255-1298.**
- **Step 66-Journaling. Pages 1299.**
- **Step 67-Letting The World Do The Work For You. Pages 1300-1305.**
- **Step 68-Journaling. Pages 1306.**
- **Step 69-Letting The World Do The Work For You. Pages 1307-1312.**

IV. Step 4- Do Decision Making For Deep Work, Studying, Learning and Personal Growth.

A. Part 12: Deep Work and Decision Making.

- **Step 78- Slow Down. Pages 1348-1350.**
- **Step 79-NOT MULTITASK. Pages 1351.**
- **Step 80-You Have Required To Do The Work For Decision Making. Pages 1352-1367.**
- **Step 81- Use Rules of Reading for Decision Making 1368-1369.**
- **Step 82-Decision Making Books. Pages 1370.**
- **Step 83-Decision Making. Pages 1371-1408.**
- **Step 84- Thinking, Logic and Mental Model. Pages 1409.**
- **Step 85-Letting The World Do The Work For You. Pages 1410-1415.**
- **Step 86-Journaling. Pages 1416.**
- **Step 87-Letting The World Do The Work For You. Pages 1417-1422.**

V. Step 5- Communication For Deep Work, Studying, Learning and Personal Growth.

A. Part 13:Deep Work and Communication..

- **Step 88- Slow Down. Pages 1424-1426.**
- **Step 89-NOT MULTITASK. Pages 1427.**
- **Step 90-You Have Required To Do The Work For Communication. Pages 1428-1443.**
- **Step 91- Use Rules of Reading For Communication. Pages 1444-1446.**
- **Step 92-Communication Books. Pages 1447-1450.**
- **Step 93- Thinking, Logic and Mental Model. Pages 1451.**
- **Step 94-Letting The World Do The Work For You. Pages 1452-1457.**

VI. Step 6-Strategy and Tactics.

A. Part 16:Deep Work, Shallow Work, Strategy and Tactics.

- **Step 111- Slow Down. Page 1603-1605.**
- **Step 112-NOT MULTITASK. Pages 1606.**
- **Step 113-You Have Required To Do The Work For Strategy and Tactics. Pages 1607-1622.**
- **Step 114- Use Rules of Reading to Analyse The Topic For Strategy and Tactics. Pages 1623-1625.**
- **Step 115-Strategy and Tactic Books. Pages 1626-1627.**
- **Step 116-A Primer on Strategy. Pages 1628-1633.**
- **Step 117-Strategy vs. Tactics: Why the Difference Matters. Pages 1634-1637.**
- **Step 118-Thinking, Logic and Mental Model. Pages 1638.**
- **Step 119- Tiny Gains. Massive Results. Pages 1639-1640.**
- **Step 120-Letting The World Do The Work For You. Pages 1641-1646.**

VII. Step 7 WRITING

A. Part 15:Deep Work and Writing.

- **Step 103- Slow Down. Page 1494-1496.**
- **Step 104-NOT MULTITASK. Pages 1497.**
- **Step 105-You Have Required To Do The Work For Writing. Pages 1498-1513.**
- **Step 106- Use Rules of Reading to Analyse The Topic For Writing. Pages 1514-1516.**
- **Step 107-Writing Books. Pages 1517-1521.**
- **Step 108- How To Become Straight A Student. Pages 1522-1594.**
- **Step 109- Thinking, Logic and Mental Model. Pages 1595.**
- **Step 110-Letting The World Do The Work For You. Pages 1596-1601.**

VIII.Step 8- Performance.

A. Part 20:Deep Work and Performance.

- **Step 148-Performance Books. Pages 1957.**
- **Step 149- Tiny Gains. Massive Results. Pages 1958-1959.**
- **Step 150-The Ultimate Deliberate Practice Guide: How to Be the Best. Pages 1960-1980.**
- **Step 151-Review, Reflection, Review and Accountability. Pages 1981-1982.**
- **Step 152-Improvement. Pages 1983**
- **Step 153- Feedback System In Place. Pages 1983.**
- **Step 154-Repeat. Pages 1984.**
- **Step 155-Letting The World Do The Work For You. Pages 1985-1990.**
- **Step 156- Spend 5k-10k Hours On subject to Become Expert. Pages 1991.**

IX. Step 9- Review, Journaling and Visualisation

A. Part 25: Journaling and Review of 6 Month And Month.

- **Step 171-Materials Needed and Listen And Follow Rules of Reading For Journaling and Review of 6 Month And Month. Pages 2083.**
- **Step 172-Reflect. Pages 2084.**
- **Step 173-Analyse Strength and Weaknesses. Pages 2085.**
- **Step 174- Analyse Threats and Opportunities. Pages 2085.**
- **Step 175- Improvement. Pages 2085.**
- **Step 176- Steps to Take To Do Better and Improve. Pages 2086.**
- **Step 177- Ideas and Gratitude. Pages 2086.**

B. Part 26: Journaling and Review of Week.

- **Step 178-Materials Needed and Listen And Follow Rules of Reading For Journaling and Review of The Week. Pages 2088.**
- **Step 179-Reflect. Pages 2089.**
- **Step 180-Analyse Strength and Weaknesses. Pages 2090.**
- **Step 181- Analyse Threats and Opportunities. Pages 2090.**
- **Step 182- Improvement. Pages 2090.**
- **Step 183- Steps to Take To Do Better and Improve. Pages 2091.**
- **Step 184- Ideas and Gratitude. Pages 2091.**

X. Step 10- Use Flashcard. Flashcards are an amazing way to learn paired associations between questions and answers.

XI. Step 11- Active Recall. After learning something try to write all that you can remember on a piece of paper. Actively recalling the information WITHOUT ANY HELP. If you are capable of reproducing the information verbally, in your own words without looking at the textbook, you got it.

XII.Step 12- The Question Book Method. Take notes by rephrasing rather than writing down the exact wordings.

XIII.Step 13-Self-generated challenges. Create challenges for yourself to solve later.

XIV.Step 14-Closed-book learning. Limit your ability to look for hints.

XV.Step 15-Don't give up on hard problems easily. The more you push through hard problems, the easier your problem-solving skills get.

XVI.Step 16-Prove things to understand them. Your understanding can be an illusion and the only way to know for sure is to prove your knowledge of things.

XVII.Step 17-Always start with a concrete example. Humans learn mostly by doing so it is important to create concrete examples.

XVIII.Step 18-Don't fool yourself. Ask lots of questions to check your understanding.

XIX.Step 19- Train Memory:

- A. Mom (motivation, observation and Method).**
- B. Linking words to Images (Visualisation).**
- C. Linking new information to old information (Association).**
- D. Add emotion.**
- E. Creating a story to link sequence of words.**
- F. Use LOCI story method. The loci story method is basically the story method with one additional feature: Your story involves you going through different parts of a setting (such as a house), and each setting has one object that represents something in the list your trying to memorize. The benefit of this method is that you don't have to come up with a new story every time. You just use the same story, except you change the items in each setting. For example, you can imagine a big mansion with 10 rooms, and during the story you walk through all 10 rooms. In each room you find a different object, which you can change to suit the list you're trying to memorise. Again, you have to make the story vibrant by using visualisation, association, and emotion.**

8. Rule 7- In the Exam

I. Step 1- Use How To Be Straight A Student.

A. Step 194- How To Be Straight A Student. Pages 2248-2320.

II. Step 2 Plan-What you will write before writing anything down. It is extremely important to review the entire exam and skimming through all the questions. This will allow your brain to think about the topics and you'll have a better understanding of the overall difficulty and length of the exam. The next thing that you need to do is to formulate a rough schedule for answering the questions. If you are pressured by time, you should keep a few minutes as a safety buffer and distribute the remaining time as needed among the questions. By doing this, you ensure that you have enough time to go through the entire exam and that you won't get too absorbed by a single difficult question.

III. Step 3- Proceeding- Starting with the questions you can answer easily. The proceeding to answer the more difficult questions.

IV. Step 4- Proofreading- leaving yourself time at the end to go over everything. Check all the answers and fix any typos and double check your grammar. If you have spare time, you can check whether or not you might be able to improve any of your answers.

I Will Read or Listen Like AudioBook On Phone, On Daily Basis And Apply TO The Task, Deep Work, Deep Studies, Learning and Studies.

Stage 14:Post Deep Work.

Stage 5: Rules and Step To Take After Deep Work is Done.

- 1. Rule 1- Clean up Your Desk, and Put everything in their Places.**
- 2. Rule 2- Set Time For Family and Family Stuff.**
- 3. Rule 3- Set Time for Bible Read or Listen and Prayer.**
- 4. Rule 4- Set Time For Meditation.**
- 5. Rule 5- High Quality Leisure During Downtime. The Reason Prioritise Downtime?**

- I. Downtime Improves Our Thinking - Have you ever hit a roadblock in your work and ended the day in frustration, only to come back the next day with a perfectly formed solution? This is the power of the pause. Allowing your mind to rest lets you work through complex challenges with greater clarity than if you powered on empty. As Newport notes, “Providing your conscious brain time to rest enables your unconscious mind to take a shift sorting through your most complex professional challenges.”**
- II. Downtime Replenishes Our Ability to Practice Deep Work - Deep Work makes the case that “you can restore your ability to direct your attention if you give this activity a rest.” After work, don’t direct your attention to high-priority tasks. Instead, give your mind uninterrupted rest through activities like gathering with friends or family, cooking, or walking in nature. Adversely, sneaking in extra emails or group chat conversations does not allow for true rest.**
- III. Our Ability for Deep Work is Finite - Unfortunately, as valuable as deep work is, it can’t be done in unlimited quantity. Newport suggests the upper limit for deep work per day is four hours. Beyond this, our ability to direct focused attention diminishes. Given this, there is plenty of time in the evening to make room for the downtime that will serve your deep work sessions the following day.**

IV. List Of Down Time High Leisure Activities:

- **Walk.**
- **Run.**
- **Cooking.**
- **Spending Time With Family.**
- **Repair things.**
- **Read.**
- **Get New Hobby.**

6. Rule 6-Reviewing, Journaling and Visualisation. Use Rules of Reading to review My Day. If you've had a negative week, make changes to your schedule to cut out factors that led to it.

7. Rule 7- Set Time For Auditing Time Spent. Audit how you're spending your work time. Reflect on and tweak your schedule: Newport suggests reviewing the accuracy of your time blocks at the end of each day. This will help you set more accurate goals and expectations in the future. Ask Questions.

I. Did I reach My Goal For Number of Hours Spent On Deep Work This Week? Yes or No.

II. How Many Items ON My Daily Plan Did I complete?

8. Rule 8- Exercise On Daily Basis.

9. Rule 9-Eat Right: You required energy for you to last long time, stamina, efficiency.

I. Use Keto Diet.

II. Check The Food and The Minerals I need to intake.

III. Do Intermittent Fasting. Between 18/6 to 23/1

10. Rule 10-Sleep Helps To Learn and Focus: Just like downtime helps your brain process the information you've been absorbing, sleep does that multiplied manyfold. Sleep is essential. We simply cannot overstate the importance of good sleep. The Best Thing that Anyone Can Do for Mental Health, Physical Health and Performance in Athletic or Cognitive Endeavours is to make sure that you are getting enough Quality Sleep, enough of the time for you.

- I. Step 1-Avoid viewing bright lights—especially bright overhead lights between 10 pm and 4 am.**
- II. Step 2-If you wake up in the middle of the night (which, by the way, is normal to do once or so each night) but you can't fall back asleep, consider doing an NSDR protocol when you wake up.**
- III. Step 3-Expect to feel really alert ~1 hour before your natural bedtime.**
- IV. Step 4-Keep the room you sleep in cool and dark and layer on blankets that you can remove.**
- V. Step 5-Drinking alcohol messes up your sleep. As do most sleep medications.**
- VI. Step 6-Kids (and indeed all of us) have changing sleep needs over time. Adjust accordingly.**

Two Core Abilities for Thriving in the New Economy

- 1. The ability to quickly master hard things.**
- 2. The ability to produce at an elite level, in terms of both quality and speed.**

This ability to learn hard things quickly, of course, isn't just necessary for working well with intelligent machines; it also plays a key role in the attempt to become a superstar in just about any field—even those that have little to do with technology. To become a world-class yoga instructor, for example, requires that you master an increasingly complex set of physical skills. To excel in a particular area of medicine, to give another example, requires that you be able to quickly master the latest research on relevant procedures. To summarize these observations more succinctly: If you can't learn, you can't thrive. Now consider the second core ability from the list shown earlier: producing at an elite level. If you want to become a superstar, mastering the relevant skills is necessary, but not sufficient. You must then transform that latent potential into tangible results that people value. Many developers, for example, can program computers well, but David Hansson, our example superstar from earlier, leveraged this ability to produce Ruby on Rails, the project that made his reputation. Ruby on Rails required Hansson to push his current skills to their limit and produce unambiguously valuable and concrete results. book: The two core abilities just described depend on your ability to perform deep work. If you haven't mastered this foundational skill, you'll struggle to learn hard things or produce at an elite level
